VOLUME II

Foreword

It is commonly assumed that we are now living in a new knowledge economy, a post-industrial society. Groundbreaking developments in digitalisation and biotechnologies have led cyber gurus to assert that everything in the digital future will be different. Industrial technology may have had a patriarchal character, but digital technologies, based on brain rather than brawn, on networks rather than hierarchy, herald a new relationship between women and machines. Perhaps the link between technology and male privilege is finally being severed.

The realities of women's lives belie these simple generalisations. Certainly we are living in a very different world than that of even 30 years ago, and digital technologies increasingly mediate every area of our lives. This makes it even more imperative that we examine the extent to which existing societal patterns of gender inequality are transformed or reproduced in a new technological guise.

So, I am delighted that Eileen Trauth has taken on the mammoth task of bringing what is now a vast literature on gender and information technology together in these two volumes. In recent years, there has been a great deal of feminist writing on information and communication technologies. Studies on the Internet, cyberspace, and computer science, for example, have strengthened our analysis of how technology as a culture is implicated in the construction of masculinity. It demonstrates that the symbolic representation of technology remains sharply gendered. At the same time, feminist theory increasingly works from the basis that neither masculinity nor femininity are fixed, unitary categories but rather they are constructed in relation to each other. As a result, we now have a much more complex understanding of gender, of technology, and of the mutually-shaping relationship between them.

Cutting through the hype, this encyclopedia examines the relationship between gender and technology in all the major spheres of our lives. The theoretical approach that it adopts is much needed in an age when deep-seated technological determinism underpins much of the current debate on subjects as diverse as the ecological crisis, food safety, and genetic engineering. This determinist view represents technology as a separate sphere, developing independently of society, and can lead to pessimism about the possibilities for change. The rich collection of articles collected here certainly points in the opposite direction, providing a multiplicity of examples of activities, campaigns, and programs that are reshaping the landscape of women's relationships with machines.

The encyclopedia has many strengths, but there are two in particular that I would like to mention. The first is its interdisciplinary nature. The strength of gender theory over the last three decades has been its ability to cut across traditional disciplinary divides that not only made women invisible, but produced narrow, limited forms of knowledge. The most exciting developments in social science have been in areas that crosscut these old boundaries, and this encyclopedia exemplifies the fruitfulness of this approach. The authors cover a huge range of disciplines and approaches, and we are the richer for it.

The other notable feature of the book is that it uniquely contains contributions by authors from all over the world. Contemporary feminist studies of technology are characterised by more sensitivity to "the politics of difference" than some of the earlier literature. There is a much clearer realisation that gender, that what it is to be a woman, is experienced everywhere through such mediations as race, age, class, sexual orientation, history, and colonialism. Information technologies clearly have very different implications for Third World and First World women, within and between regions and countries. To date, this literature has been dispersed and hard to find. Now, given the comprehensive scope of this encyclopdia, we will be able to compare women's situation in different contexts, and our analysis will be enriched as a result.

I highly recommend these two volumes. They will be invaluable not only for academics and students, but for policy makers, educators, and the interested general reader. The authors represent a wealth of expertise and are at the leading edge of research in this area. If we are to transform gender power relations in the 21st century, we need a fully-rounded understanding of the relationship between gender and information technology. Eileen Trauth can be congratulated for providing us with just that.

Preface

As information technology has spread to all corners of the world and to all aspects of personal and work life, so too, has grown an interest in understanding more about the diverse characteristics of those who use, develop, and are affected by information technology (IT). This is a significant development because understanding the diverse characteristics of both developers and users has ramifications for the way in which work is done, user requirements for systems are understood, and interaction with computer-based tools is accomplished. One important aspect of this human diversity is gender. What has accompanied this increased interest in the role of gender diversity in understanding IT development and use, in recent years, has been heightened research interest in the influence of gender on information systems and technology.

As a result, a large and diffuse body of research related to the role of gender in human interactions with information technology has emerged in recent years. This body of research spans a number of disciplines including: information science and technology; information systems; computer science; engineering; education; women's studies; gender studies; labor studies; human resource management; and science, technology, and society. The focus of this research has been on issues such as similarities and differences between women's and men's use of information technology, variation in relationship to IT among members of each gender group, the effect of gender combined with other diversity characteristics (such as race or ethnicity) on IT use, and the underrepresentation of women in the IT profession. The audience for this research includes parents, educators, managers, policy makers, and other researchers. However, because this literature is located in so many different disciplines a number of problems have arisen. First, for students and scholars, it is difficult to locate the corpus of relevant gender research literature when one wants to learn about or is engaged in gender and IT research. Second, it is difficult for educators, policy makers, managers, and other consumers of this literature to find the relevant material. Consequently, there is a need to bring this research literature together into a single reference source.

The idea for a compilation of research on the topic of gender and information technology originated in 2001. While attending a panel on women and IT at an information systems conference in Australia, several of us who are engaged in gender and IT research bemoaned the lack of coherence in the research. The problem, as we saw it, was that too little research is informed by the existing literature. Instead, too much research appears to be informed by anecdotal data or personal bias. Hence, current research on gender and IT is making less of a contribution to cumulative knowledge about this topic and less of an impact in addressing the issues than it could. At that gathering, we began to talk about the need for a book that would bring together this disparate body of research literature. The opportunity to produce such a book came three years later when Dr. Mehdi Khosrow-Pour of Idea Group Inc. asked me to edit an encyclopedia on the topic of gender and IT. In accepting this invitation, my goal for this book was: (1) to bring together the research literature from all the different disciplines that are producing research about gender and information technology; (2) to bring together the gender and IT research from around the world; and (3) to produce a comprehensive resource that could be the first source to which people would turn to learn about the current state of research on gender and information technology.

What has resulted is this two-volume *Encyclopedia of Gender and Information Technology.* It is an international compilation of research on the topic of gender and information technology, representing a broad range of perspectives. Contributions to this important publication have been made by scholars throughout the world with notable research portfolios and expertise, as well as by emerging investigators. This encyclopedia provides comprehensive coverage and definitions of the most important issues, concepts, trends, and research devoted to the topic of gender and IT. It contains more than 200 articles highlighting this state-of-the-art research. These articles are written by scholars from around the world who are engaged with research into the influence of gender on the development and use of information technology as well as the impact of information technology on men and women. These articles include extensive bibliographies that, taken together, represent an exhaustive reference source for both the interested reader and the scholar engaged in research in the area of gender and IT.

In order to ensure that this encyclopedia has both geographical and disciplinary breadth, an international Advisory Board was established. The members of this Advisory Board introduce this volume by presenting overviews of their research programs in order to illustrate the ways in which the topic of gender and IT is being addressed in different countries.

To assist readers in navigating and identifying needed information, this two-volume encyclopedia has been organized by listing all entries in alphabetical order by title throughout the two volumes, and by including the title in the "Table of Contents" in the beginning of each volume. This important new publication is being distributed worldwide among academic and professional institutions and will be instrumental in providing researchers, scholars, students, and professionals with access to the latest knowledge related to research on women and men with respect to information technology.

Eileen M. Trauth, PhD
Editor-in-Chief

Acknowledgments

As editor of this encyclopedia, I would like to acknowledge the help of those individuals involved in the various phases of this project, without whose support this encyclopedia could not have been satisfactorily completed. I would like to begin by thanking Dr. Mehdi Khosrow-Pour of Idea Group Inc. for inviting me to undertake a project that I had wanted to do for several years. I would also like to thank the staff members Renée Davies and Michelle Potter at Idea Group Inc. who worked closely with me on the production of this encyclopedia.

I would like to thank the members of the Advisory Board—Alison Adam, Jane Margolis, Helen Richardson, and Liisa von Hellens—for their help in recruiting contributions to this encyclopedia and for writing the introductory articles for it. I would also like to thank the authors and the reviewers for their contributions to this two-volume encyclopedia. Without the interest and commitment of individuals around the world who are engaged in gender and IT research, this encyclopedia would not have been possible.

I would like to extend my deepest gratitude to my colleagues in the College of Information Sciences and Technology at The Pennsylvania State University who made this encyclopedia a reality. They helped me shepherd each article through the process from solicitation and proposal, to submission, review, and revision, to the final product. This encyclopedia could not have been accomplished without their diligence and dedication. Three research assistants—Haiyan Huang and Allison Morgan, working under the direction of Jeria Quesenberry—learned, firsthand, about the trials and tribulations of academic publishing as they developed the encyclopedia Web site, managed the article submission system, tracked down reviews, reminded authors, followed-up on revisions, and collated the finished product. David Hall, Associate Dean for Research, provided resources when necessary to complete this project, our Information Technology Office, and in particular, Steve Murgas and Ed Putt, who helped us with the project Web site and submission system, and Tracy Ray from our Research Office saw the final manuscript to completion.

Finally, I would like to thank Kathy Driehaus for her understanding and support, and for patiently listening to me talk about this project.

About the Editor

Eileen M. Trauth, PhD, is a professor of information sciences and technology and director of the Center for the Information Society at The Pennsylvania State University, USA. Her research is concerned with societal, cultural, and organizational influences on information technology, information technology work, and the information technology workforce. Her investigation of socio-cultural influences on the emergence of Ireland's information economy is published in her book, *The Culture of an Information Economy: Influences and Impacts in the Republic of Ireland.* She is currently engaged in a multi-country study of women in the information technology workforce in Australia, New Zealand, Ireland, and the U.S. Dr. Trauth has published nine books and over 100 research papers on her work. She is an associate editor of *Information and Organization* and serves on the editorial boards of several international journals. Dr. Trauth received her PhD in information science from the University of Pittsburgh.

An Agenda for Research on Gender Diversity in the Global Information Economy

A

Eileen M. Trauth
The Pennsylvania State University, USA

INTRODUCTION

There has been considerable interest of late in the topic of diversity in the IT field. This topic engages the spectrum of IT stakeholders from academics to funding agencies to industry groups to practitioners. Academic research on diversity has appeared in special issues of journals such as *Information Technology and People* (Adam, Howcroft & Richardson, 2002) and has become a conference theme for ACM SIGMIS CPR (Trauth, 2003) and IFIP 8.2 (Trauth, Howcroft, Fitzgerald, Butler, & DeGross, 2006). In the United States the National Science Foundation has funded gender research under the rubrics of the IT Workforce (ITWF), Broader Participation (BP), and Science Technology Engineering and Mathematics (STEM) funding streams. Industry groups such as the Information Technology Association of America (ITAA) have sponsored conferences dealing with diversity. Perusal of corporate Web sites gives evidence of the incorporation of diversity goals into corporate policy.

The focus of attention—whether from a practitioner or an academic perspective—is generally about how to achieve greater diversity in the IT labor force. A significant component of this diversity quest is the recruitment and retention of women in the IT field. Underlying this discourse, however, is the assumption that we currently possess the conceptual tools to understand the reasons for the lack of gender diversity in the IT field and that we know how to apply this knowledge to the task of redressing this situation. However, there are some of us who would challenge these unexamined assumptions. We would argue that part of the reason for the underrepresentation of women in the IT field is the absence of a sufficient examination of these assumptions. This, in turn, suggests a need for theoretical innovation along with the application of interventions.

In response to this need, a research program has been established at the Center for the Information Society at The Pennsylvania State University. Housed in the College of Information Sciences and Technology, this research program has both theoretical and application goals. The theoretical goal is to broaden the theory base used to understand the underrepresentation of women in the IT field. The application goals are to translate this understanding into public and corporate policy, and curricular interventions. The remainder of this article presents an overview of a research agenda for gender diversity and the IT sector that was established in order to respond in a meaningful and productive manner to the diversity challenges and opportunities being presented to the 21st century IT labor force.

THEORETICAL STANCE

The objective of this research agenda is to develop theoretical tools that help us uncover the meaning behind the statistics about the underrepresentation of women in the IT workforce. It is being achieved by focusing attention on the *differences among women*, that is, the variation that exists within a gender group rather than across the two gender groups. In doing so, this approach stands in contrast to the body of gender and IT research which focuses attention on the *differences between men and women*. The motivation for adopting this theoretical perspective arises from the awareness that gender roles, expectations, and stereotypes regarding women's involvement with information technology vary significantly when factors such as nationality, race, age, sexual orientation, marital status, socio-economic status, and education level are taken into account. To date, data from Australia, Ireland, New Zealand, and the U.S. are being used to articulate and empirically test a theory of individual differences to explain the underrepresentation of women in the IT workforce.

The contribution of the Individual Differences Theory of Gender and IT is that it focuses on differences among women in the ways they experience and respond to characteristics of IT work, the IT workplace, and societal messages about women and IT. The goal of this research is to engage in field-based theory refinement by examining the particular ways that female IT professionals are influenced by and react to the social shaping of both gender identity and IT.

DIVERSITY RESEARCH AGENDA

Elsewhere in this *Encyclopedia* the Individual Differences Theory of Gender and IT is discussed in greater specificity as are details about the theory testing research that has been conducted to date. The purpose of the discussion here is to provide an overview of the research agenda and how it is being enacted.

Field Studies of Gender and IT

Field studies have been conducted in several countries in order to further develop and conceptually test the Theory of Individual Differences as it relates to IT and gender. The purpose of these studies is threefold: (1) to identify characteristics associated with women who have successfully negotiated the IT field, (2) to deepen our understanding of environmental influences on female participation in IT, and (3) to document the variation in definition of male/female competencies, men's work, women's work, and women's responses to generalized societal messages about the IT field as a male domain.

The earliest study in this research program on gender and IT was conducted in Ireland between 1989 and 1999 as part of a larger study of socio-cultural influences in the development of Ireland's IT sector.[1] In that study, gender was not the specific focus of the attention; it was but one of a number of socio-cultural factors being explored (Trauth, 1995, 2000). A subsequent research project, which began in 2003, is investigating the impact of Ireland's information sector on Irish society. In this research, a study of women in the IT sector is an explicit component.[2] Here, the focus is on ways in which the position of women has changed as the information economy has become more central to Ireland's overall economic development (Trauth, 2004).

A third research project was undertaken in Australia and New Zealand in 2000. The focus of this study is on understanding how women negotiate the largely male domain of the information technology profession. A particular emphasis of this study is the influence of race, ethnicity, nationality, and culture on a woman's development as an IT professional (Kvasny & Trauth, 2002; Nielson, von Hellens, Beekjuyzen, & Trauth, 2003; Trauth, Nielsen, & von Hellens, 2000, 2003; von Hellens, Nielsen, & Trauth, 2001).[3] It was in the course of conducting this research that the theoretical perspective of individual differences was first explicitly articulated (Trauth, 2002).

Research in the United States began in 2002 with a multi-year investigation of women in the American IT workforce.[4] The purpose of this research is to empirically refine and test the Individual Differences Theory of Gender and IT (Morgan, Quesenberry, & Trauth, 2004; Quesenberry & Trauth, 2005; Quesenberry et al., 2004; Quesenberry, Trauth, & Morgan, 2006; Trauth, Huang, Morgan, Quesenberry, & Yeo, 2005a; Trauth & Quesenberry, 2005, in press; Trauth, Quesenberry, & Morgan, 2004; Trauth, Quesenberry, & Yeo, 2005b).

Research Methods

While a consistent research methodology and theoretical perspective have been employed in all of these gender studies, the epistemological underpinning has evolved as this research agenda has progressed. Qualitative methods have been employed in each of the projects. This consists of open-ended interviews that are complemented by participant observation and document analysis. The interviews are focused around the life histories of the participants. That is, women IT professionals are asked to describe their educational and career journeys that brought them to their current position in the IT field. These interviews draw from a script but are quite open-ended in structure. They typically last 90 minutes in duration and are recorded for later transcription and analysis.

Since the theoretical lens for this research is directed toward a better understanding of variation in receipt of societal messages and individual responses to them, this research has sought to explore the varied individual and environmental influences on women working in the IT profession. Hence the interview questions probe regional cultural influences, as well as varied individual experiences and influences.

At the outset, the epistemological orientation was completely interpretive. It was chosen over the dominant epistemology—positivism—because the objective was not to conduct hypothesis testing of established constructs. Rather, this research sought to articulate the emergent constructs of the Individual Differences Theory by developing a better understanding of the influences on women in the enactment of their careers. This was pursued by exploring the manifestation of individual differences in the women's work-life narratives. However, as this research agenda has proceeded, more recent projects have moved toward a critical epistemological orientation. As this has occurred, the focus has shifted from an exclusive emphasis on the woman's subjective representation of her career history to her reflection upon (and the researchers' critical analysis of) contradictions, and the role of external forces and power relations in shaping her decisions and behaviors (Howcroft & Trauth, 2004; Kvasny, Greenhill, & Trauth, 2005).

Future Research

Future work in this research agenda will involve further empirical testing of the various constructs of the Individual Differences Theory drawn from the interview data sets. It will also involve more extensive data collection methods such as survey research. Whereas the research, to date, has focused on women at one end of the career pathway—those who are already in the labor force—future work will also extend the examination of individual differences in relation to information technology to secondary school and university women students. The Theory of Individual Differences is also being applied to a study of masculinity and femininity in IT adoption. Finally, this research is becoming incorporated in an investigation of the role of human diversity in the development of a knowledge economy.

In addition to this work, four doctoral candidates are exploring gender diversity in IT in their own dissertation research. Jeria Quesenberry is employing the Individual Differences Theory of Gender and IT in an extension study of the underrepresentation of women in the IT profession. The objective of this study is to more deeply investigate the role of organizational factors in the underrepresentation of women in the IT profession in order to further test some of the constructs in the theory. Haiyan Huang is investigating methods for coping with gender as a feature of cultural diversity when engaging in global, virtual IT development. As part of this research she is examining cross-cultural influences on gender and their implications for work teams. Allison Morgan is employing the Individual Differences Theory of Gender and IT in a study of Web search capabilities of diverse individuals. The objective of this study is to better understand how greater attention given to the diversity of individuals can influence system design in order to overcome the digital divide. Benjamin Yeo is exploring the theme of social exclusion based upon gender as part of his study of socio-cultural factors influencing the development of sustainable knowledge economies in several countries.

CONCLUSION

At the heart of this research agenda on the underrepresentation of women in the IT profession is the recognition that the IT sector is global in nature. Hence, national characteristics, geography, economy, cultural factors, race, and ethnicity must also be taken into consideration when attempting to explain the relationship between gender and information technology. The initial work in this research program emanated from the effort to understand gender as one of a number of socio-cultural factors influencing the development of a nation's information sector. This global perspective has remained an essential feature of our research agenda. The twenty-first century is witnessing greater global dispersion of the IT sector. Therefore, it is fitting, we believe, for a U.S.-based research program to develop an understanding of gender and IT within the context of a better understanding of the global information economy.

Facing and Changing Reality in the Australian IT Industry

Liisa von Hellens
Griffith University, Australia

Sue Nielsen
Griffith University, Australia

Despite recent setbacks, the Australian information and communications technology (ICT) industry is one of the fastest growing and innovative sectors of the Australian economy with a sustained average annual growth rate approaching 12%. This is more than two and a half times the average growth rate of the Australian economy as a whole. The ICT industry is a sector in its own right but is also transforming all other industries and areas. In fact, about 60% of ICT professionals work outside the ICT sector. In 2005, Australia had 355,600 employed ICT professionals spread across all sectors of the economy (DCITA, 2006). This represents 3.6% of the workforce and is higher than in Europe (2.5%) and the USA (about 2.8%) (Petersen, Revill, Ward, & Wehmeyer, 2004).

However, recent figures from the Australian Bureau of Statistics (2003) show women comprising only about one fifth of the ICT workforce. There are different ways of measuring female participation and success but the general conclusion is that women are not only in a minority but also are concentrated in the lower level, lower paid, and lower skilled jobs in this industry. The proportion of females employed in ICT roles varies among sub-sectors; telecommunications services and manufacturing sectors are the lowest (18% and 19% females, respectively) and computer services is the highest (26% females).

The gender distribution across core IT roles shows that women are over represented in the groupings that tend to have lower formal qualifications such as computer support technicians. Statistics do not identify jobs that require "hybrid" skill sets (e.g., graphic designer or business analyst) which may be more appealing to many women. Australian labor force statistics also show that women with a background in marketing and public relations dominate occupations in digital industry management. A significant proportion of females are in occupations in the Internet and multimedia, digital industry management, and industry positions requiring high IT proficiency, such as graphic designers and illustrators.

In the tertiary education sector, admission statistics for core IT programs show declining numbers for student retention generally, and for female students in particular. Women with IT qualifications changed from 36.5% out of the total 90,704 individuals with tertiary IT qualifications in 1996 to 30.5% out of 153,183 in 2001 (Bell & Staehr, 2004). A report on industry statistics prepared for the Women in ICT Summit held in September 2005 revealed that the number of entering university students fell by 24% between 2001 and 2003, and that in 2003, of the 11,866 new students enrolling in undergraduate IT degree courses in Australia 80% were male (Department of Communications, Information Technology and the Arts (DCITA), 2005). The Australian Council of Professors and Heads of Information Systems (ACPHIS) which consists of IS professors in business and information technology schools is extremely concerned with the low student numbers and lack of women. This item has been on the agenda at the annual meetings in both 2004 and 2005. Similar concerns have been expressed by the Council of Computer Science heads. These data exist against a backdrop of overall decline in IT/IS majors in business schools, forcing IS schools to downsize their staffs.

A good deal of research and intervention has been carried out to improve the participation of women in the Australian IT industry, but the field is still too new for any conclusions to be drawn about the effectiveness of the large number of intervention programs or to understand the impact of research on perceptions of the problem. The WinIT project (discussed elsewhere in this *Encyclopedia*) is typical of research in this area, aiming to study the results of action programs as well as to investigate perceptions and behavior of potential and existing students and IT personnel. The motivations are also typical, deriving from ethical concerns about equity and representation as well as practical considerations regarding the health of the industry. However, research in this area is complicated by problems in defining the nature of the IT industry and the role that women might play in the industry.

Firstly, a lack of clarity as to what constitutes the IT industry and the rapid rate of change complicate attempts to understand the reasons for the declining participation of women in the IT industry, as well as the declining interest in IT degrees. Concerns regarding equity are based on an "equality" view of women's participation, in which women can do anything that men can do. A "difference" view of women entails considering how women might contribute "special" attributes and skills to a masculinised industry. However, the notion that women who work in the IT industry may provide some important "female" perspective and influence, which would represent and serve the interests of women as an undifferentiated group, is very contentious. The WinIT project has taken a social construction view, regarding the construction of ideas such as "female" and even "information technology" as an ongoing and negotiated process. However, regardless of how "female" is defined, the exclusion of women from an important industry limits the development of the industry within a wider context of social change and limits the capacity of women to negotiate their social identity in the "information society."

Research shows that the "masculinisation" of the IT industry makes it unattractive to many men as well as to most women. To what extent this is associated with other aspects of western culture is not yet clear, since many industries seem to transcend national culture differences. Therefore, it is important to understand how the IT industry may change over time and how the participation of women may be facilitated.

There are many programs, initiatives, and interventions aimed at women and female students across Australia which provide the opportunity not only to take action but also to carry out action research. The interventions for female students are generally: awareness raising, demystifying the industry through role modeling and mentoring; presenting career options; and improving the understanding of how technology fits with business and different industries. Interventions aimed at women are more focused on support and leadership, with themes such as mentoring, preparing for board positions and networking opportunities.

Although the effectiveness of these interventions cannot yet be assessed, there is considerable support in Australia for such programmes. A prime example is the efforts of the Minister for Communications, Information Technology and the Arts, Senator Helen Coonan. She established an Advisory Group to help her plan a Women in ICT summit that was convened in September 2005. Fulfilling an election promise, the Advisory Group was made up of prominent Australian women from both the ICT and education sectors. The Group was established to help identify key issues that needed to be considered at the summit. The intent of the summit was to feature high profile participants representing the industry, government, and academia. Breakout sessions would then focus on four topics: how the ICT professions should be represented; how to make the ICT workplace attractive for women; how to ensure that curriculum design and career advice address Australia's ICT needs; and how to coordinate future activity to enhance women's participation in ICT.

With respect to future activity, the group supported a national approach to enhancing women's participation in ICT while acknowledging that existing bodies already working on the problem would be playing an important role. For example, a National Communications umbrella organization—AWISE (Australian Women in IT and Science Entity) has recently been formed to represent a collaborative voice connecting ICT networks for women and girls. The Founding Board is populated with women active in the area of interventions for women and girls across Australia who are already involved in the many intervention programs run by state and federal government departments, education institutions, and industry organisations that have been introduced to interest more women in ICT education and careers. The group has five goals: to be a national single point of contact; to encourage more females to enter ICT;

to share information and initiatives; to be a centralised national body to influence government and media; and to obtain national funding to support agreed upon initiatives.

The group intends to maintain a national presence for certain initiatives that could result in greater exposure for the ICT industry. This would occur through regular planned awareness-raising activities and programs to either encourage females into the industry or to support them working and studying in the industry. One of the planned initiatives is a national role models day that is currently held in three states across Australia, with the support of national funds and media. This would allow the program to become more regular, more supported, have more exposure, and become part of the "norm". At least three events are planned for 2006. The aim is to have up to 7,000 female students in Australia participating in the events. Another planned initiative is to build on the success of the Queensland WIT scholarships and awards program by running it nationally. In a similar way, having a national scholarship presence would result in greater exposure for women in the industry as well as offer females from all over Australia the opportunity to win a scholarship and be rewarded. A third initiative of the group is setting up a national Board Readiness Program for women working in the industry. Also building on the success of one of Queensland's WIT Programs, this initiative will help women develop the skills and attributes necessary for them to join and contribute successfully to Board positions. The program will provide support, advice, and a structured program for women in the industry.

Australian research is tending towards action research in this area. The reflexive nature of social science research means that investigations into female participation may also contribute to the reproduction or transformation of relevant social factors. However, the effects of earlier research are not yet clear. There is a possibility that the focus on negative factors inhibiting female participation may even contribute to the perpetuation of those factors amongst the subjects studied, in the same way that media attention on the problems in the IT industry may have contributed to declining student interest. Hence, there is a strong motivation to make change while at the same time studying the effects of these changes. In such a rapidly developing industry as IT, we need to move quickly if we are to have any impact.

Helen Richardson
University of Salford, UK

INTRODUCTION

In this article we showcase the work of the GRIS group at the University of Salford in the United Kingdom. Alison Adam and Helen Richardson have been working in the field of gender and IS for many years and have recently been awarded funding from the European Social Fund (ESF) to research the under-representation of women in the IT labor market in the UK. Claire Keogh and Angela Tattersall are research fellows working on the WINWIT (Women in (North West) Information Technology) and DEPICT (Directing Pay in Information and Communications Technologies) projects and Karenza Moore and Marie Griffiths are research fellows working on the WINIT (Women in Information Technology) project. In this account we discuss the theoretical foundations of our research and our work to give gender and IS research a voice. We then present brief findings from research to date that encompasses the IT labor market, gender and online learning and in particular government strategies purported to encourage women to engage with the information society, gender, and home e-shopping, and the contribution of feminist ethics[1] to IS research.

GIVING A VOICE TO GENDER AND IS

The GRIS group at Salford consists of two faculty members (Adams & Richardson) and four researchers on funded research projects (Griffiths, Keogh, Moore, and Tattersall). In our research, we aim to bring a solidly theorized position based on feminist theory to practical empirical research on women and gender in IT and IS. In taking such an approach we critique work which adopts an often tacit liberal position[2], which does not address underlying reasons for underlying inequalities between the men and women in IT and IS[3]. We see such work as having a political dimension, where inequalities should be identified and described.

The Salford approach is exemplified in a seminal paper by Adam, Howcroft, and Richardson (2004), where we discuss a decade of neglect and reflect on the field of gender and IS, hoping to stimulate a new area of discourse and offer insight into the topic of gender in IS. The basic argument presented is as follows. First, the topic of gender is inadequately studied within the IS discipline. This is evidenced in the dearth of published papers on this topic in highly-ranked IS journals. Second, the concept of gender in IS research largely lacks theorization. IS is a field of research which has its core concern as "the development, use and impact of information technology in business and organizational settings" (Myers & Avison, 2002, p. 3). Within this article we provided a detailed analysis of recent research, which highlights a number of problems as statistical studies often take gender to be an unanalyzed variable. The gender implications of potential transformation, from new information and communication technologies, continues to be ignored. As noted elsewhere (Lohan, 2000; Wacjman, 2000), gender must be taken into account if we are to achieve a fuller understanding of technologies.

When considering the question as to why the issue of gender is largely neglected and under-theorized in the IS literature, one explanation lies in the development of IS as a discipline. The field is comparatively new and many academics are often placed in a minority position within their respective institutions, aligned with a range of diverse disciplines, such as computer science, management science, and organizational science. Many of the disciplines from which IS has arisen have been primarily associated with the functionalist paradigm which focuses on the development and use of information systems in narrow technical terms, often disregarding their organizational context. As a consequence, much time has been preoccupied with resisting technologically deterministic views of technology and by arguing for recognition of social and organizational issues.

This reaction against functionalism has been coupled with a desire for intellectual respectability and the need to create a niche for IS as an emerging discipline. As a result, it is seen as essential that "proper" research topics are established and unfortunately gender does not appear to fall within these parameters. Any claims regarding gender are claims about how we frame our social, political and organizational existence, yet these are seen as potentially threatening to the core of IS. Consequently, this adds to the dearth of research on gender and IS. Hence, we create a self-fulfilling prophecy, as the tacit lack of legitimacy of gender and IS as a research topic results in little or no attempt to progress in the area, and it then becomes viewed as a topic unworthy of publication and projects.

Dichotomizing Gender: A Problem of Statistics and Alternative Approaches

In studies which we critique in Adam et al. (2004), population samples are surveyed and gender is seen as a dichotomous variable, where specific differences in the genders are looked for and where corresponding hypotheses are of the broad form: women will do some behavior less or more than men do the same behavior. We argue that this style of statistical analysis forces gender into polarized masculine and feminine categories, therefore emphasizing differences between the two and reinforcing stereotypes. Statistical studies which cite gender differences can be analyzed endlessly, but at some point one needs to consider the deeper, underlying reasons for women's absence from the technical sphere.

Hence, we wish to contribute to research which goes beyond the traditional commentary of "add-more-women" and are instead pointing towards directions where future research on gender and IS could lead. Members of the GRIS group acted as guest editors for a special issue on gender and IS of the more critically-inspired journal *Information Technology and People* in 2002. This included: an examination of socio-cultural influences on women in the IT profession (Trauth, 2002); a consideration of discourses that represent male and female workers' social and technical skills in the software development industry (Woodfield, 2002); a study of contradiction and resistance in nursing information systems (Wilson, 2002); and an analysis of the role of gender in the domestication of computers in the home environment (Habib & Cornford, 2002). Similarly, a recent paper by Adam (2002) provides a critique of the total neglect of gender issues by IS researchers concerned with the Habermasian notion of emancipation.

GENDER AND THE IT LABOR MARKET

Our research into the UK labor market is funded by three European Social Fund projects. The aim is to consider the underrepresentation of women in the North West UK and throughout England and also to address salary secrets[4] and pay discrimination in the ICT sector[5]. In this section we focus on the state of gender and the IT labor market. In particular, we report on the key issues and themes raised by a series of in-depth interviews and an online questionnaire which were undertaken as part of our field work conducted throughout 2004.

A recent comparative survey of the IT workforce in Germany, Holland and the UK indicates that women are hemorrhaging out of the UK IT workforce. Although women are making inroads into technical and senior professions, there remains a "feminization" of lower level jobs, with a female majority in operator and clerical roles and a female minority in technical and managerial roles (Platman & Taylor, 2004).

The results of our research suggest that women often have a hard time in the IT industry, including having to accommodate a long hours culture where flexibility often means constant availability (Hoque & Noon, 2004). This culture serves to marginalize and undermine women. Our interviews with individual women in the IT industry enabled us to explore in more depth concerns raised by past and contemporary academic work, such as that of Morgan, Quesenberry, and Trauth (2004) on the existence of "Old Boy's Networks"[6] in the IT industry—we were better able to understand the organizational and socio-cultural context in which these women's experiences are embedded.

We report very briefly on some of the issues raised through our empirical work.

On What Constitutes "Working in IT"

Our interviewees and questionnaire respondents expressed job satisfaction particularly with the opportunity to combine technical skills and knowledge with "people" and communication skills. However, it is notable that these often highly technically skilled women play down their technical knowledge when talking about their work in general terms, preferring to think of their role as using technology to manage and/or help people. A striking initial feature is the vehemence of women saying "I'm not in IT but…," "I'm in sales," "I'm in the people part of the organization," "I'm a manager"—overwhelmingly "I'm not in IT."

On Being an "It" in IT

The situation of being a woman and issues of self and identity at work in male dominated IT workplaces was often discussed. As one respondent put it:

I have almost forgot that I'm a female in this business, I'm not denigrating being a woman in any way but I've almost had to push aside being a female and get on with the job like any man would do.

We argue that the ways in which women in our study distanced themselves both from IT and from their gender demonstrates that women struggle to become comfortable with gender identities in relation to IT as IT is so often related to masculine technical skill. In our study this often manifested itself in terms of a loss of confidence in the women we interviewed.

On Masculinity and Organizational Culture: Exclusion from Masculine Spaces

There is evidence of male-dominated informal social networks within the IT sector. Women felt excluded from masculine technical work in intangible ways and yet other forms of exclusion may actually be spatial in nature, in terms of women in the IT workplace being discouraged from using certain technologies, or being excluded from particular "male" spaces, as an interviewee detailed:

It took me half a year to gain access to my own training lab, because my guys considered that no girls or females should be allowed in the lab so I asked "Can I just go and see it?" and (they responded) "women are not allowed in the lab, what are you going to do there?" *I said "Excuse me there must be a difference as a manager. I must be allowed in even if it is just to look around. I'm allowed in. I'm a manager."*

GENDER AND ONLINE LEARNING

Research about Information and Communication Technologies (ICTs) in society is often set in the context of the "new orthodoxy" (Huws, 2003) using phrases such as the "era of ubiquitous computing," "information society," or "global knowledge economy." In this context from all corners of the globe, the online revolution is proclaimed. The imperative is to connect; to shop, work, learn, be governed, even fall in love online. Government initiatives proliferate globally, stressing the urgency for citizens to "engage" with ICTs. ICTs are being introduced to the teaching and learning process at an increasing pace. E-government ministers are particularly concerned about the "have-nets" and "have-nots" in this "digital revolution." Yet research in schools and the HE (Higher Education) sector looking at women learning online have indicated barriers. French and Richardson (2005) discuss how gendered relations in the home, work and education go far beyond having access to information technology (IT). They illustrate how these relations contribute to the shaping of the gendered experiences of using technology in education.

Women's overall participation in Higher Education in the UK has actually exceeded the numbers of males, yet women are choosing not to follow IT and computer science as a degree option. Women lack knowledge of IT and computing as a career and have an image of computer science as nerdy, geeky, anti-social, machine-orientated, mathematical and solitary. The finding that there are relatively few women lecturers in IT reinforces the idea that IT and computing is a male domain. If women students have to consult male lecturers, professors, and tutors every step of the way, then this gives a clear message about the world of IT and technology. Schools and universities reproduce gendered expectations about the use and capabilities of IT (Mahony & Van Toen, 1990) and computer scientists as "experts" have continued to create a "chilly climate for women" (Crawford & MacLeod, 1990).

GENDER AND HOME E-SHOPPING

Helen Richardson began this research in 1998 at the height of the dot-com boom. At the time the literature was divided. In the utopian "hyped" fantasy world, the High Street by now would have ceased to exist (De Kare-Silver, 1998). It was predicted that we would all be engaged in shopping through various media and shopping would have been transformed beyond recognition. On the other side of the spectrum, commentators suggested that e-shopping would have "no impact" (Markham, 1998) and would be an irrelevance. Of course the dot-com collapse in 1999 dented the e-shopping hype; nevertheless, the dot-com myths (Howcroft, 2001) still reappear and reinvent themselves when the next "revolutionary" media appears on the scene.

Home e-shopping though, enables consideration of engagement with ICTs in the very personal and private sphere and how technologies become embedded into everyday life. This research considers domestication of ICTs into the household—a political and contested social space (Silverstone & Hirsch, 1992) where scarce resources have to be competed for (Green & Adam, 1998).

Studies of home e-shopping need to be set in the context of cultures of consumption particularly in an "era of ubiquitous computing." We are being urged to consume and to engage with ICTs in the home. We are encouraged to use PCs in the home as an aid to study, for leisure, for electronic governance, and to e-shop, using a variety of home-based media.

Home PC ownership also has a strong association with the daily bombardment of digital divide rhetoric as well, demanding an individual commitment and responsibility to "self-help." In other words, the message is embrace the ICT "revolution" or be a victim of digital "have-not-ness" brought about, it is implied, by personal inadequacy and culpable neglect. Many people are living busy lives with an overload of domestic and work commitments in the everyday struggle to "make ends meet." Use of ICTs in the home in this context is just another thing to be dealt with.

A clear theme emerging is that household maintenance tasks are not shared equally and so there is unequal access to "spare time." Households are home to a plethora of technological gadgets associated with leisure and communication. What is absent is the leisure time to use them. Moreover, there are tensions and contradictions evident with home e-shopping where the household is also encouraged to be an arena for individualistic consumption as well as an arena for family life and relationships.

G

GENDER AND COMPUTER ETHICS

Alison Adam has been researching this area for the last five years (Adam, 2005). Computer ethics[7] research is often gender blind except for statistical studies which look at whether there are differences between men's and women's decision making in relation to computer ethics problems. Instead, a feminist approach would de-emphasize ethical decision making, looking instead to problematize gender in relation to topics such as privacy, hacking, cyberstalking, surveillance, and so on, arguing that many of these topics cannot be fully understood unless the gender dimension is analyzed. Importantly, this approach also looks to feminist ethics rather than traditional ethical approaches to emphasize care and relational networks over individual moral agents.

For instance, considering gender in relation to hacking it might be supposed that this involves the question of whether there are any women hackers. Whilst this is certainly of interest, Adam (2005) argues that there are other important issues in relation to gender and hacking. A feminist analysis of the "hacker ethic" reveals that the apparently egalitarian ethic of the hacker serves to exclude those who are not educated middle class males without family responsibilities.

CONCLUSION

In this account we have showcased the work of GRIS at the University of Salford. We intend to continue our research into many aspects of gender and information systems to shape this critical research field in our quest for transformation and emancipatory change.

ENDNOTES

1 Feminist ethics is an alternative form of ethics inspired by feminism which emphasizes relational moral theories such as maternal ethics or an "ethics of care."

2 That is, adopting an unspoken or implicit political position which recognizes that there are inequalities but does not explore the deeper structural reasons for inequalities.

3 "IT" is meant to refer to information technologies such as computers, modems, printers, etc. The term "ICT"—information and communications technology—is the broader term and is often used to encompass network technologies. However, "IT" is the older term and many people use this term to include network technologies, even though, strictly speaking, "ICT" should be used. "IS"—information systems—encompasses the study of IT and ICT in social and organizational settings.

4 Salary secrets are the situation in many IT jobs where salaries are kept confidential—often on pain of dismissal—this conceals gender pay discrimination.

5 See the project Web sites at http://www.isi.salford.ac.uk/gris/winit and http://www.isi.salford.ac.uk/gris/winwit.

6 Old Boy's Network refers to male informal networks which serve to promote and support men in organizations and which exclude women and so act as a barrier to women's progression.

7 Computer ethics is the study of ethical problems in relation to computers and ICTs.

Social Change Research and the Gender Gap in Computer Science

Jane Margolis
University of California Los Angeles, USA

Allan Fisher
iCarnegie, Inc., USA

INTRODUCTION

At Carnegie Mellon University, home to one of the top computer science departments in the country, only 7% of the students in the entering computer science class in 1995 were women. By the fall of 2000, that proportion had risen to 42%. While the percentage of women entering has declined slightly, likely reflecting the bursting of the Internet bubble, Carnegie Mellon's female computer science enrollment remains at about 30%, far higher than the average among research departments of computer science. Today, in 2005, the Carnegie Mellon School of Computer Science, with its increased number of female students, is a changed place. What sparked this development?

The story of the research that served as a catalyst for these increased numbers can be found in our book *Unlocking the Clubhouse: Women in Computing* (Margolis & Fisher, 2002). In this book we lay out the blueprints—the walls, doors, and windows—of the "boys' clubhouse" of computing education. We describe some specific institutional changes, enacted both by us and by others at Carnegie Mellon, which resulted in increasing the recruitment and retention of women students. These changes range from rethinking admissions criteria; contextualizing computer science ("computing with a purpose"); paying attention to students' experiences and the department culture; accommodating a wide range of previous computing experience; recognizing that women and students who do not fit the prevailing norm are disproportionately affected by problems like poor teaching, unapproachable faculty, or hostile peers; providing students with a broader picture of what it means to be in computer science, other than the hacker stereotype; outreach to high schools; and the formation of a vibrant women's organization.

In this article we offer reflections about some of the critical factors that contributed to our research becoming an instrument for social change. We provide some "lessons learned" for other institutions that are thinking about addressing the gender gap in their computer science departments. While the Carnegie Mellon developments began with a body of research, we do not believe that extensive research is necessary for all institutions. However, it is important to understand the local situation well enough to customize a general set of strategies. While people rightfully want to learn from successful initiatives, and not "reinvent the wheel," the constitution of each department—its history, the culture, the demographics, the leadership, the pressure points, what is known and not known about the experiences for women students—will differ from institution to institution. In most cases, but not all, initiatives can be modeled after existing programs by understanding the commonalties and differences between the situations. To achieve this, some straightforward data gathering, as opposed to in-depth research, is usually called for.

Here we present brief summaries of "lessons learned" from our research on the gender gap in computing. We believe that what we learned applies to planning an intervention as well as to conducting research.

ADDRESSING THE PROBLEM

- **Understand Your System and Know Your Numbers:** While lessons from other settings and other "diversity projects" can be instructive, the critical question is how this all applies to your own institution. The management truism that "you can't improve what you do not measure" applies here. Where is the bottleneck in your department? Is it in admissions? Is it in retention? When are people being lost? How many women students are in the department? How many women faculty? How does this compare to other technical departments in your institution? What are the retention rates of women in computer science? What have the trends been? What is the culture of your department? How do women experience the department? And, where are the relevant points of intervention within your department?

Local information is also critical to community engagement. While information about the gender gap from other places can be imported, especially when you have a "convinced audience," there is nothing like shining the light on your own backyard, and providing evidence from your own students, to make an institutional community take notice. The Carnegie Mellon research was based on some 300 Carnegie Mellon student interviews, over a 4-year period of time with a core sample group of 50 male and 50 female computer science students. We also conducted observations of computer science classes, and held interviews with computer science administrators and faculty. We lived in the department (Allan as Associate Dean of Undergraduate Education and Jane as Visiting Research Scientist) and were familiar with it from the inside.

- **Leverage Interdisciplinary Expertise:** Our research was conducted by an interdisciplinary team. Jane is a qualitative researcher with a background in Education and Women's Studies. Allan is a computer scientist and at the time of our research was Associate Dean of Undergraduate Education in the Carnegie Mellon School of Computer Science. While we originally referred to our research partnership as an "insider-outsider" collaboration (with Allan as the insider and Jane as the outsider), we quickly realized that since we were studying the dynamics of the gender gap in computer science, both perspectives were at the core of the problem. Neither perspective was on the margins. Each of us had a key to the puzzle that the other lacked. This both equalized our collaboration and opened up the range of issues that could be investigated. Our collaboration explored the traditionally unspoken issues that impact women's experiences such as confidence, sense of belonging, and different male and female motivations for studying computer science.
- **Listen to Students Holistically:** It was students' experiences (and our eagerness to hear from women's perspectives) that led us to the trouble spots in the department. But, to learn about those experiences we had to construct an interview guide that allowed us to learn more than the "party line," and more than what was "safe" to talk about. We also needed to construct a process that allowed interviewees, speaking in confidence to third parties, to talk about topics not commonly discussed in computer science culture. Open-ended questions that encourage interviewees to describe and shape their own accounts of their experiences (such as "Can you tell me the story of you and computers?" or "Can you tell me about your decision to major in computer science?"), rather than choosing amongst pre-selected generic answers, were critical to this process.
- **Take the Long View vs. a Single Snapshot:** We conducted multiple interviews with our sample of students, following some students over a four-year period of time. This longitudinal approach allowed us to take more than just a single snapshot of students' experiences. The multiple interviews allowed us to observe the evolution of students' relationship to computing. At any point along the way had we drawn premature conclusions about the student, we would have an incomplete and misleading story. We learned that we cannot think in terms of a static set of influences on students' experiences but rather must understand students' stories in terms of a web of influences and a sequence of turning points, at each of which a different set of factors may be critical. These webs of influence were only apparent over time. Long term funding from the Alfred P. Sloan Foundation made this possible, and senior faculty member Lenore Blum

and Carol Frieze have been able to use other sources of support to investigate ongoing cultural changes within the department since. We emphasize again, though, that large-scale research is not required for effective interventions—but tracking the numbers is.

- **Understand the Dynamics:** One of our interview questions was: "Can you describe your fellow computer science students?" Male and female students gave similar descriptions of their colleagues: myopically obsessed, living and breathing computers 24/7, emerging occasionally from behind the computer with a "monitor tan." Students' responses to this "geek mythology" were interesting. Despite the fact that both male and female students had similar descriptions of their fellow computer science students, about two thirds of the women and one third of the men explicitly dissociated themselves from the stereotype: "But that's not me." Yet the widely held perception of computer science students as being interested in nothing but computing became a set of expectations against which students judged themselves. Listening to the students tell of their experiences, we heard how each student's self-evaluation becomes a critical part of his or her sense of belonging in computer science. We heard how the obsessed computer whiz kids became the reference group—a frame of reference for each student's self-assessment. As a result, some students felt a good fit between their preferences and this model of what it is like to be a computer science student and others did not. Women fell disproportionately into this latter category.

  We then saw how this sense of being outside of the norm makes women students especially vulnerable to other injuries such as poor teaching, inhospitable learning environments, and unhelpful instructors. When compounded by feeling outside the norm, seemingly small and sometimes unintended slights often are magnified. All of these chip away at a student's confidence. This, in turn, often leads to a loss of interest in the discipline. We saw once-enthusiastic students, mostly female, in a descending spiral of eroding interest and confidence, driven by negative comparisons to peers and by a variety of environmental insults.

  One key observation on these influences is something that we have come to view almost as the First Law of Educational Diversity: in a situation with in-groups and out-groups, "everything bad happens worse" for the members of the out-groups. Because of doubts about fit, comparisons with members of the in-groups, and the feedback between confidence and interest, bumps in the road—poor teaching, lack of advising, weed-out experiences, and so forth—disproportionately create disaffection and attrition among the out-groups. Note that a corollary of this observation is that many effective interventions in favor of diversity are good for *all* students.

SHAPING A RESPONSE

- **Make a Leadership Commitment:** Because the initial impetus for this project came from Allan, who was an "insider" with authority over the undergraduate program, there was an unusual level of legitimacy associated with this research. It has been all too common for gender investigations to be marginalized and not taken seriously. Because of Allan's position in the department and the fact that the project was part of the department (with a department office and a title granted to Jane as Visiting Research Scientist), a legitimacy was bestowed on the project that we believe helped facilitate information gathering and cooperation from different members of the community. This commitment was continued after our departure from the scene by Lenore Blum, who has had extensive experience in gender projects, and Peter Lee, Allan's successor as Associate Dean, with support from University leaders as well.
- **Focus on the Bottlenecks:** At Carnegie Mellon, we were "losing women" in two main ways: at admission time, where all three of application, acceptance, and matriculation rates were lower for women than for men; and in the early years of the curriculum, where nega-

tive experiences and a sense of "lack of fit" created disproportionate attrition among women. In other settings we have seen, introductory courses, processes for choosing one's major, and "weed-out" courses have posed bottlenecks. We believe it is critical to monitor such bottlenecks over time, and to focus interventions there.

- **Attend to the Basics:** A few powerful heuristics apply to almost all settings. Programs should provide mentoring and community, multiple pathways into the curriculum for students with differing levels of experience, a high-quality and positive learning environment, and should develop a culture that supports and celebrates multiple approaches to the study of computer science.
- **Paint a Broad Picture of Computer Science:** Most CS faculty think of computer science as a dynamic, multi-disciplinary field that combines aspects of mathematics, engineering and science and has application in nearly every field of human endeavor. However, many prospective students, including some of the most enthusiastic, inherit from high school and society a narrow notion of computer science as focused on computers and on coding. Addressing this ongoing legacy is a key challenge for the computing community. Further, the introductory sequences of traditional curricula often reinforce narrow images of the field, by focusing primarily on equipping students with the programming tools they will use in later, more diverse courses. Carnegie Mellon's response to this issue has included the addition of an "immigration course" introducing new students to the breadth of the field. Other institutions have developed introductory courses that use integrative projects, that focus on principles over programming, or that link computer science to applications, to help to broaden students' vision.
- **Catalyze and Support Women's Community:** Upon her arrival at Carnegie Mellon in 1999, Lenore Blum led the creation of Women@SCS, an organized group of women in computer science. A professional group like this plays several important roles. Perhaps foremost, it provides an environment for women to experience being female computer scientists together with others, without feeling the need to "learn to speak 'boy'" (as eloquently phrased by Anita Borg) in order to be in the field. In this vein, it provides a venue both for professional development experiences and for mutual support. The most successful instances of such groups seem to combine substantial student leadership with ongoing faculty support.

  Beyond its direct impact on its membership, a women's group increases the visibility and influence of women in the larger community. At Carnegie Mellon, the women's group has developed representation on standing committees, has organized events for the entire community, and has developed a variety of recruiting and outreach activities—even assisting in the creation of women's groups at other institutions.

SUSTAINING PROGRESS

- **Leverage Critical Mass and "Virtuous Cycles":** At Carnegie Mellon, changes in admission policy (removing previous computing experience as a preference factor, and emphasizing leadership potential in addition to numeric predictors) were an important factor leading to the increased enrollment of women. With more women classmates, female students no longer felt as isolated. And, as these talented and able women students had more of a presence in the department, faculty and administrators began to recognize how the increasing numbers of women in the program made the program even stronger and enhanced its competitive advantage. This, in turn, helped to make the environment ever more appealing to women students.
- **Watch the Student Experience Like a Hawk:** In most academic settings, especially in large institutions, key interactions with students are factored across multiple organizations: admissions, academics, student affairs, housing, career counseling, and so forth. Each of these areas presents opportunities to foster or weaken a student's affiliation with a discipline. We believe it is critical to work cross-

functionally both to provide students with positive experiences and to head off the oversights that can miss such opportunities or, worse yet, drive students away. While Carnegie Mellon's reputation and recruiting power played a key role in the rapid increase in the involvement of women in computing, we believe that the university's culture of working across organizational boundaries was also an essential factor; at various times, we were able to work closely with admissions staff, other colleges, the student affairs office, and others to address specific issues.

- **Adapt:** Especially in a field like computing, with its rapid technological change and dynamic business cycle, change is a constant. The students whom we first studied were among the first generation to grow up with personal computers as a pervasive presence in the home; ten years later, a new generation has grown up with the Internet and all it implies. Ten years ago we saw the first inklings of the Internet boom, and now we have been through boom, bust, and consolidation. As we write this, perhaps the key human resource challenge to the discipline of computing in the developed countries is the public perception that "all the computing jobs are going offshore" to the developing world.

  Just as the external environment changes, communities change. Lenore Blum and Carol Frieze have observed a shift in the Carnegie Mellon computer science student culture, in which both men and women are likely to take a broad and connected view of the field, and in which the traditional gender stereotypes of computing are largely defused. In light of internal and external changes, it is necessary to adapt dynamically to new sources of challenge and advantage.

CONCLUSION

Our research challenges the assumptions we often heard (and still hear): that women are less suited than men to do computer science, or that the subject is "just boring" for women and girls. Instead, our research shows the weighty institutional influences that steal women's interests in computer science away from them. It is critical to recognize the "First Law" effect, that women and other students who do not fit the prevailing norm are disproportionately affected by problems within the "computer science pipeline."

The goal should not be to fit women into computer science as it is usually conceived and taught. Instead, as we suggest in *Unlocking the Clubhouse*, "a cultural and curricular revolution is required to change [the culture of] computer science so that the valuable contributions and perspectives of women are respected within the discipline." Ultimately, this revolution serves not only the interests of the women involved, but those of the discipline itself.

Gender and Information Technology General Content

Access and Use of ICTs Among Women in Jamaica

Nancy Muturi
Kansas State University, USA

A

INTRODUCTION

Information and communication technologies (ICTs) have made the global village a reality with the Internet, cell phones and other digital communication technology disseminating messages instantly through the fast information superhighway. The United Nations (U.N.) Development Program (UNDP, 2001) defines ICTs in terms of innovations in microelectronics, computing (hardware and software), telecommunications and opto-electronics—micro-processors, semiconductors and fibre optics. These technologies enable the processing and storage of enormous amounts and rapid distribution of information through communications networks. As new innovations, ICTs are also described as "the building blocks of the networked world," (UNDP, 2001, p. 30), with ICTs, particularly the Internet, being used by a variety of organizations as a global networking tool.

Access to, knowledge of and effective use of ICTs is crucial, particularly where access to the technology is equated to social, political, economic and human development. Internet usage, for example, is regarded as the standard indicator of the use of ICTs and also the most democratic of all mass media, mainly because of their low investment (Internet World Stats, 2006). This technology has been used effectively as a tool for delivery of various services and applications, including distance learning, agriculture, telehealth, e-commerce and e-governance. Individuals, organizations and institutions now use the Internet to strategically reach a large audience of markets through e-mails and other advertising strategies, since it is fast and economical, irrespective of size or location of business.

There are many gender issues, however, related to connectivity and access to available ICTs, some of which are visibly documented and most often examined as the digital divide based on gender. Rakow (1986), in her classic studies on gender and ICTs, however, points out that technology should not be examined based on the differences in the behavior of men or women towards a technology, but instead to look for the ways in which the technology is used to construct us as women and men through the social practices that put it to use. Rakow further argues that more attention needs to be paid to how communication technologies alter, aid, or construct women's opportunities for interacting with each other and with the wider public domain.

This article is based on data gathered through a detailed open-ended questionnaire, with a sample of 121 Jamaican women, ages 21 and older, and explores their access and nature of use of ICTs as well as challenges they face in their attempts to use them effectively. Like other Caribbean islands, Jamaica has embraced ICTs as a tool for national development, adopting the most recent technologies to ensure global connectivity. The study examines how these technologies could be used effectively to address some of the developmental, economical, health and human developmental challenges that face the Small Island Developing States (SIDS). These findings are used to complement existing studies, including national surveys and literature on the gender and ICT issues in the Caribbean.

BACKGROUND

Gender analysis has been applied to virtually every social, economic, political and environmental field of study, including communication technology. The latter is an area of research that has attracted interest among researchers, scholars, practitioners and policy-makers from various disciplines. Over the years, such interests have ranged from the "social shaping of technology" tradition (MacKenzie & Wajcman, 1999) to gender involvement in production and use of technologies (Henwood & Hart, 2003; Robins, 2002; Shade, 2002, 2003). These studies have questioned the existing gender imbalances in ICT access and use while at the same time recognizing the possibilities that technologies allow for gender equity and empowerment (Cooks & Isgro, 2003).

Gender equality is integral to a human rights-based approach to development (Hafkin & Odame, 2002) and for sustainable development. Since the early 1990s, ICTs have been pushed as a tool for women's empowerment and development, but the effort heightened by the U.N. declaration of the Millennium Development Goals (MDGs). Goal 3 focuses on gender equality and empowerment of women as a contributor to "free out fellow men, women and children from the abject and dehumanization conditions of extreme poverty" by 2015 (UNDP, 2005). This is done through advocating and supporting active participation of women in development while recognizing their triple role in production, reproduction and community work.

Today, a vast majority of women in developing countries use ICTs for information dissemination and retrieval, while others, mostly women's organizations, use the technology to network with other agencies in their area of operation; search for grants and other support from the international community; and promote their activities online. In Latin America and the Caribbean, there has been a felt need for gender and development through access and effective use of ICTs. One of the most successful information networks for women is in Latin America, where a gender and ICT project was initiated following an urgent need for news with a gender perspective. As a result of this need, a feminist activist in Mexico, who felt the lack of communication and the need to link women's organizations nationwide, launched the creation of an electronic communication network with minimal infrastructure and some previous training in e-mail. With a group of women they started the *Mademmujer*, an information and communication network that aimed to strengthen women's participation (Plou, 2003).

When ICTs are accessible, affordable and designed to support specific needs for analysis, storing and exchanging information, they can enable people in all sectors of society to accomplish tasks that otherwise would be too costly or impossible (Commonwealth, 2001). Several other organizations worldwide recognize that the benefits of public recognition for concerns that have been private and hidden can provide for women in contexts that would otherwise have remained peripheral or invisible.

The Jamaican ICT Situation

ICTs have been adapted in the Caribbean to a great extent within the government ministries, non-government organizations(NGOs) and the private sector, a trend that was exacerbated in the wake of the 2001 World Summit on the Information Society (WSIS). The summit facilitated the creation of an environment through which the full power of ICTs can be brought to bear on the issue of development to the benefit of all. The government of Jamaica, for example, has made the integration of information technology (IT) into the economy a high priority and a strategic imperative, thus facilitating the diffusion process. The Ministry of Commerce spearheaded this effort by having recently added "Technology" to its name to read Ministry of Commerce, Science and Technology (MCST).

Diffusion of ICTs in Jamaica has taken several approaches, but the most visible is the training efforts by government and academic institutions. Two government-supported institutions—the HEART Trust and National Training Agency—offer a range of critical skills necessary to compete in the labor market. Courses offered include MS Office; basic and intermediate IT; call center; worker training, including data entry; networks; and programming, in concert with the Caribbean Institute of Technology. These programs have had about 70% female enrollment since 1999 (Francis-Brown, 2003). At the tertiary level, the University of the West Indies has played a leading role in IT training along with the neighboring University of Technology. The Caribbean Institute of Media and Communication (CARIMAC), with 90% of female students enrollment, has a stronger focus in ICT training, offering undergraduate and graduate courses in effective use of the technology while enabling access to the technology for institutional affiliates. The graduate program, Masters in Communication for Social and Behavior Change (CSBC), launched in 2004, for instance, provides laptop computers with wireless Internet connection to participants as part of the package while the University installs hotspots on various parts of campus. Providing access to online resources and connectivity has triggered the interest and possibility of developing and offering online courses, even with limited human resources.

Women's Access to ICTs

Like the wider Caribbean, the majority of women in Jamaica have access to the most common communication technologies. Though this was a small study, findings indicate that the ICT adoption situation in Jamaica is impressive, with more than 80% of women interviewed having access to a variety of common ICTs—Internet access (81%), cell phones (99%), cable/digital TV (83%) and radio (98%), among others. The finding on Internet access is in line with the national study by the Market Research Services Ltd. (MRSL) commissioned by Jamaica Promotions Corporation (JAMPRO), which found a universal 91% awareness of the Internet among Jamaicans 15+ years. That study sought to establish current awareness and usage of the Internet, attitudes and intention to use it, and found that close to 70% of those aware of the Internet had used the Internet and the remaining 30% had an intention to use it within a short term or as soon as they gained that access.

Mobile phones have also become a permanent feature in everyday communication for women in Jamaica and the wider Caribbean. This is visibly so where prepaid mobile phones are overwhelmingly accessible to literally everyone who can afford a minimum about United States (U.S.) $25 with free activation and no signed contracts or other commitment to the provider. Making calls using a mobile phone within and outside of the Caribbean is the most inexpensive way to keep in touch, especially with free incoming calls. About 49% do text messaging, another form of affordable communication, and 3% access the Internet, while 21% play games on their phones. This, however, varies with age, where older women use their phones exclusively for making calls.

With regard to Internet access, about 98% of women in Jamaica have access to the Internet, which implies access to computers and at various locations, including home (61%), work (33%), school (15%) and other places, like the post office, public library, and friends' houses. A small minority (9%) have access at Internet cafés and a negligible 3% through their mobile phones. This small percentage is directly related to the high cost involved accessing the Internet at the cafés and via mobile phones, but one respondent noted, "Some young people use their phones to get 'blue movies,' [meaning accessing pornographic sites] and to download pictures for their phones' screens as screen savers." The Internet cafés were also not very popular with women, due to their location. Some women who had to take public transportation feared the risk of molestation either in the buses or the cafés, a major limitation for women with no access elsewhere.

Main reasons that women went online included checking e-mails (78%) and information gathering or research (74%). This included Web surfing, participating in newsgroups and other listservs. They accessed gender- and health-related information, such as chronic diseases, obesity and weight loss, mental health, cancer; and reproductive health topics, such as sexually transmitted diseases including HIV/AIDS, which has become a woman's disease affecting more Caribbean women and girls than men. Gender-based violence, a regional problem requiring multisectoral attention, is another issue that organizations such as Women's Media Watch, Sistren Theatre Collective, Crisis Center, Bureau of Women's Affairs, Woman Inc. and Fathers Inc., among others, address. The organizations go online to learn about strategies applied by other women's organizations globally and to network with others addressing the same issues.

FUTURE TRENDS

Given the current ICT situation in Jamaica and available infrastructure and support from the Caribbean governments, there is much to look forward to in the application and use of the technology as tools for human development and gender empowerment. There are limited or no problems in relation to mobile phone use as more service providers emerge in the region. Their cost effectiveness and convenience has led to their replacement of land lines in some homes, though 80% use that form of communication in addition to mobile phones. This wide access and use of this technology has prompted researchers to explore ways in which this technology could be used effectively to address some gender and development issues in the Caribbean. Health and gender organizations are currently exploring how information could be effectively disseminated to women and the wider population through mobile phones. This, however, requires ICT policy development and guidelines for such use. It is observed that policies are made to increase access and use of ICTs at various levels as a strategy for gender empowerment and capacity building without any regard for the social and cultural needs among women or other disempowered groups (Wajcman, 1995).

There are also challenges associated with Internet access and use among women, including lack of computers (51%), lack of training (56%) and lack of Internet connection (41%). The availability of land lines and monthly costs for Internet connection (at least US$35 per month) limit connectivity, and only a very few people island-wide have wireless connection. The broadband connection is gradually venturing into the Island, but costs are prohibitive for the majority of the Jamaican population. Other challenges include social, cultural and policy factors in training and other gender biases in ICT application use, ownership and other gender biases. This affects the level and type of IT training that women receive, where men become techno-savvy while women assume less-skilled ICT-related responsibilities and, therefore, less compensation. Observations indicate that as soon as the new technology starts to produce income, it is often taken over by men (Paris, Feldstein & Duron, 2001). However, women have recognized the need for training as a ticket to self-empowerment, competence and self-efficacy.

Many programs in Jamaica attempt to empower women in use of technologies in the region, but more needs to be done in providing access at various levels. The University of the West Indies has set a good example for other academic institutions through provision of laptop computers, a trend that others must follow. The Caribbean governments have also taken training and gender inclusion into consideration, establishing training institutions and other support for women (Muturi, 2005), thus playing a role toward the achievement of the MDGs. Similarly, some NGOs have realized the potential for ICTs in addressing gender-related issues, facing them through effectively using the Internet as a tool for networking and information dissemination and facilitating change among women and other stakeholders. The Women's Media Watch, for example, has taken the responsibility to support the training of its members, offering basic IT courses to willing participants, and continues to use the Internet for networking with members locally and abroad. Recently, the organization started an online newsletter, sharing information with its members and sponsors on current projects and activities in Jamaica.

CONCLUSION

It is now acceptable globally that women's participation in development is crucial, but they need to have the necessary IT skills and education for competence in a male-dominated field. Though the majority of organizations use the Internet for information dissemination, limited studies assess communication efficiency and effectiveness of the current strategies particularly targeted for women. Mobile phones, on the other hand, are easily accessible to every woman, but many Jamaican organizations have not explored their potential as a tool for achieving their development goals, reaching their target audience directly with information and at their own time and space. This, however, requires a larger study, to explore how these technologies could be effectively used to address developmental challenges such as poverty, gender disempowerment and several vulnerabilities facing the SIDS, including natural disasters such as hurricanes, tsunamis and earthquakes but with more serious consequences among women.

Gender-sensitive policies need to address the major women's concerns, including social, cultural, economic and political factors, and security issues that deter their active participation in ICT access and effective use. This article underscores the fact that such factors are unique to every country and society, and Jamaica is no exception; but research in this area is inadequate. It must be recognized that even with the global diffusion of ICTs and their applications, access to some technologies in the low-income countries is still limited and requires more attention.

KEY TERMS

Diffusion: The adoption and implementation of certain innovations, products, services or practices that have been promoted and found effective in achieving certain goals. Application and effective use of communication technologies among women has been viewed as one strategy for achieving human development goals through gender equity and empowerment of women.

Empowerment: Term commonly used in the area of gender and development referring to provision of skills, access to information and ability to make choices, and self-efficacy and self-esteem. Gender empowerment enables men and women to have equal opportunities and to participate in activities that contribute to human development.

Gender: Society's construction of femininity and masculinity. Gender to some extent determines access and use of technologies and gender roles in relation to ICTs.

Human Development: As defined by the United Nations, it is about an environment in which people can develop their full potential and lead productive, creative lives in accord with their needs and interests. Human development considers that people are the real wealth of nations and promotes investing in them through enlarging their choices for all other forms of development.

Information Communication Technologies (ICTs): All forms of development, processing, storage and dissemination of information to a target audience in an effective and strategic manner, aimed at achieving certain communication goals.

Innovations: Any idea, product or service significantly improved or viewed as new to the target audience that it is intended for. ICTs, including mobile phones, computers and other communication technologies, are considered as communication channels as tools for development and gender empowerment.

Millennium Development Goals (MDGs): Set by the United Nations to contribute to the reduction of global poverty by 2015. These goals include: eradicating extreme poverty, providing universal primary education, combating HIV/AIDS and malaria, promoting gender equality and women empowerment, reducing child mortality, improving mental health, ensuring environmental sustainability and developing global partnership for development.

Small Island Developing States (SIDS): Small countries located in the small islands of Africa, Asia and the Caribbean and other low-lying coastal regions. These states are vulnerable to several natural disasters and challenges of developing countries due to their physical size, geographical locations and archipelagic formations. Through ICTs, various agencies have addressed these challenges.

ACM's Attention to Women in IT

Orit Hazzan
Technion – Israel Institute of Technology, Israel

Dalit Levy
UC Berkeley School of Education and The Concord Consortium, USA

INTRODUCTION

The Association for Computing Machinery (ACM) is a major force in advancing the skills of information-technology professionals and students worldwide. It was founded in 1947, and today has about 80,000 members. This article summarizes how this organization views the issue of women's participation in the hi-tech field. As it turns out, though the topic is addressed extensively in the association's newsletters and reports, women representation in these fields remains low.

BACKGROUND

This article reviews *ACM TechNews*, an e-mail newsletter that provides timely information to IT professionals 3 times a week and is directed toward the wider membership of the ACM, one of the larger associations of people working in the computing fields. Each message sent to the list consists of about 10 to 15 short news items based on articles published in various hi-tech and computing magazines and journals. The short messages refer interested readers to the full articles.

We found it interesting to survey the news published in the messages sent to this list since the items are selected from the vast body of material published in the computing field according to their relevance to the majority of the community. Thus, news published in these digests reflect, in a way, the issues this community is concerned with and conceives as important.

As it turns out, the ACM community finds the topic of women in the computing fields to be highly interesting. During the past 5 and a half years (January 2000 through May 2005), 164 messages out of some 850 that were sent to the list contained a news item related to women. For illustration, during the first 4 months of 2005, 22 messages out of 43 messages sent to the list included a news item about women. This picture clearly indicates that this community finds the topic of women in the IT fields interesting. However, as we illustrate later, most of the news address, from different perspectives, the underrepresentation of women in the IT fields.

MAIN THRUST OF THE ARTICLE

This section presents the picture revealed from our review of *ACM TechNews*. Here is one example, taken from the April 20, 2005, newsletter, of how a news item appears on the list. Out of 19 news items, the 15th item was the following one.

- **What IT Women Want:** *A virtual roundtable of successful businesswomen moderated by Kathleen Melymuka discussed the challenges faced by women in IT and what recruiters and employers should do to attract and retain them. Scites Associates President Jan Scites said "the fundamental issue for women is that very few ..". [read more]*

The "read more" link refers the reader to an expansion of this short description, in this case to http://www.acm.org/technews/articles/2005-7/0420w.html#item16.

At the end of the expanded description, there is a link (indicated by the phrase "Click Here to View Full Article") to the original article, which in this case is located at http://www.computerworld.com/careertopics/careers/story/0,10801,101088,00.html. News items that address women in the IT professions also include the following note: "For information on ACM's Committee on Women in Computing, visit http://www.acm.org/women."

In what follows, we survey the central women-related topics of news items that appeared in the *ACM TechNews* newsletters. We also add our perspective on these issues. The URLs (uniform resource locators) that refer to the ACM newsletters are presented in the footnote, and the full reference appears in the reference list.

As hinted previously, one of the main issues addressed in the ACM news digest with respect to women in IT is their low representation in the field. According to the Commission on Technology, Gender, and Teacher Education, the female portion in the IT workforce in the United States has shrunk from 40% to 20% in the last 15 years (Raimy, 2002).[1] This phenomenon is called the "shrinking pipeline" (Camp, 1997).

Similar findings were presented by the U.S. Bureau of Labor Statistics (Clements, 2002).[2] In 2003, women accounted for half of the workforce in the United States, but for only 20 to 25% of the technology professionals in that country (McCarthy, 2003).[3] A more recent report from the Information Technology Association of America shows a severe decline in the percentage of women in the IT workforce. Women held just 32.4% of IT jobs in 2004 in general, a proportion that represents a 41% drop since 1996 (Wong, 2005).[4] To summarize, in IT fields, the percentage of women fell by about half between 1985 and 1995 to just 20% (Kimberly, 2005).[5]

Although women hold about 20% percent of all IT positions, reports the American Association of University Women[7], only few women hold upper level management positions. Liz Ryan, executive director of WorldWIT (Women in Technology), an international Listserv for women in the IT field, says women still confront a "slow, uphill climb" in the industry. She says the dot-com culture was a step backward for women in some ways because of the mentality that reigned at many dot-com startups (Solomon, 2000).[6] Women working their way up through the IT ranks must struggle with gender bias, cultural stereotypes, and male misconceptions that women know less about IT than men (Hogan, 2001).[8]

Different reasons are presented as explanations for the low representation of women in the IT workforce. Here are three of them.

- **Stereotype:** It has been suggested that the low representation of women in IT results from the "geeky" image of IT workers that discourages women from pursuing tech careers (Ascierto, 2003).[9] Different attempts worldwide made to attract more women to the IT industry show that the field offers creative careers that provide social interaction and make a difference in the real world. This approach is based on the assumption that women prefer professions that involve human interaction.
- **Male Dominance of the Culture and of Networking, and the Need to Adjust to This Culture:** It is sometimes argued that the IT field is a male-dominated computing culture, and that extroversion and the unabashed promotion of one's own accomplishments are signs of intelligence, whereas the low-key, self-effacing approach that women tend to use indicates a lack of achievement (Applewhite, 2002).[10] In order to succeed and gain credibility in such an environment, women must sometimes engage in male-oriented activities (Messmer, 2003).[11] It is suggested that the agile approach toward software development (Cockbum, 2001), which recently got a lot of attention in the software industry and is largely based on communication and teamwork, may fit to women's working and management style (Hazzan & Dubinsky, in press).
- **Family-Career Conflict:** Women sometimes find it too difficult to juggle work and family (Czetli, 2003).[12] This idea is illustrated in another contribution to this encyclopedia (Hazzan & Levy, in press). In that article, we present the perspective of female software engineers in the Israeli hi-tech industry by describing six typical profiles that emerge from the analysis of our data. One reoccurring theme related to all these profiles is the family-career conflict.

In addition to the decline in the overall numbers of women in the IT fields, the ACM community discusses through its *TechNews* publication other gender-related issues. Here, we mention three topics that are frequently addressed in the ACM digest: exit rates, executive positions, and salaries. Then we highlight the topics from an international perspective and address women's skills with respect to the IT field.

Exit Rates

A survey conducted in 2001 by GLS Consulting revealed that 41% of the 265 IT women surveyed were considering leaving their positions due to the stress of balancing their work with their personal lives. Sixty-five percent said that working in the IT field has had a negative impact on their personal lives (Melymuka, 2001b).[13] The exit rate is expressed in our above-mentioned article in this encyclopedia (Hazzan & Levy, in press) by one specific profile of female software engineers. This profile describes female software engineers who leave the hi-tech industry at different stages after they become mothers. According to Armstrong (2005),[14] when women leave the IT workforce, the IT industry loses, among other things, sheer talent, women's collaboration skills, and their very different way of looking at problems. For example, Armstrong indicates that research suggests that women see more nuances and have a more holistic approach than men, who are more linear thinkers. She says, "Without both kinds of thinking, you lose the breadth of perspective that can approach a problem from multiple directions, resulting in creative solutions otherwise unavailable."

Executive Positions

According to statistics offered by the nonprofit research group Catalyst,[15] women account for only 8.1% of executives at major hi-tech firms, compared with 12% at major companies across all industries, and many women who reach the upper level of management hold nontechnical positions in human resources, marketing, and sales. Indeed, according to a survey of 1,000 women and 500 men employed in the IT industry, 62% of women said a glass ceiling exists in the IT industry; 62% of men said there is no glass ceiling. When asked if too few women have IT leadership positions, 84% of women said yes, and 57% of men agreed. However, while 75% of men said there is gender equality in the IT industry, only 56% of women agreed (Melymuka, 2001c).[16] Still, according to the U.S. Bureau of Labor Statistics, in 2003, men held 69% of the 347,000 computer and information-systems manager jobs in the United States (Brown, 2004).[17]

Salaries

According to the results of InformationWeek Research's 2002 National IT Salary Survey, the salary gap between male and female IT professionals appears to be widening. In terms of total compensation, men are making about $7,000 a year more than women. Female IT managers earn $10,000 less median total cash compensation than their male counterparts (Goodridge, 2002).[18] According to a survey conducted by the Standard, women working in the Internet industry earn significantly less than men, even when adjustments are made for education, industry, and job title. The survey, given to some 2,600 newsletter subscribers, found that women in the Internet industry earn a median base salary of $60,500, compared with $80,000 earned by their male counterparts. Meanwhile, women receive a median bonus of $7,000, which is less than half of the $15,000 median bonus awarded to men. Women responding to the Standard's survey worked 9.7 hours a day on average, while men worked 10.3 hours. In addition, slightly more than half of the women worked at least one weekend per month, compared with 61% of the men (Carr, 2001).[19]

While the above data refers mainly to the United States, the low participation of women in the IT fields is well known in many other places in the world as well. Following are two examples.

- *The number of female network professionals in Western Europe is expected to double by 2004, although they will still comprise only a small portion of the employee population, concludes an IDC report for Cisco Systems ... Out of 13 countries surveyed by IDC, France is expected to have more women in the networking industry than any other country; the participation rate is forecast to reach over 12 percent by 2004.* (Mayfield, 2001)[20]
- *In the United Kingdom, although 36% of new hires in the first quarter of 2002 were female, women represented 46% of all those leaving the field. Some women are quitting*

their careers to focus on family life, but older women are leaving as well (Fielding, 2003).[21]

The underrepresentation of women in the IT field presented above contrasts the fact that women have the needed skills for this industry and that this industry does need women. For example, it is argued that "[t]he IT industry, e-business in particular, is considered to be a more favorable working environment for women than old economy corporate America" (Vaas, 2000).[22] Furthermore, according to Irene Dec, vice president for International Investments at Prudential Financial, women possess the soft skills needed to succeed in global IT initiatives. She says, "You need people who can collaborate, build relationships, understand behavior, and women tend to be more in that play." Specifically, these people have good listening skills, socialize readily, follow other people's behavioral cues, study up on the local culture, and are patient and respectful. Indeed, soft skills alone are not enough; women must also possess knowledge and expertise to establish their value (Melymuka, 2001a).[23] With respect to management, it is believed that women make ideal managers in tech organizations based on the strength of their communication, social skills, relationship management, team building, and multitasking (King, 2004).[24] As has been mentioned above, it seems that the agile approach toward software development fits these traits of women, and may partially help in expanding the shrinking pipeline (Hazzan & Dubinsky, in press).

FUTURE TRENDS

This article illustrates the gap between the attention a topic receives and its low impact on the field. More specifically, on the one hand, the ACM news digest discusses the topic of women in IT quite extensively, yet on the other hand, the representation of women in IT remains low. This situation raises questions such as what are the roles of the associations that are supposed to deal with this issue? How can this situation be changed? How can such a discussion increase the representation of women in the IT industry? These questions are important, especially in the case of the ACM since the organization boasts a designated chapter called ACM's Committee on Women in Computing, which is described on the organization's Web site (http://www.acm.org/women) as follows: "ACM-W is the ACM committee on Women in Computing. It celebrates, informs and supports women in computing, and works with the ACM-W community of computer scientists, educators, employers and policy makers to improve working and learning environments for women."

CONCLUSION

The ACM news digest is only one mailing list surveyed for the purpose of this article. We conclude with an invitation to survey how the issue of women in the IT fields is manifested in other similar lists and forums in other places on the globe.

ACKNOWLEDGMENTS

We would like to thank the Samuel Neaman Institute for Advanced Studies in Science and Technology and the Technion Fund for the Promotion of Research for their generous support in this research.

Addressing the Gender Gap in IT via Women's Preferences in Video Games

Rashaad E. T. Jones
The Pennsylvania State University, USA

Ivanna S. Terrell
The Pennsylvania State University, USA

Erik S. Connors
The Pennsylvania State University, USA

INTRODUCTION

We feel that it is essential to ask: Why study video games as a form of information technology? Are video games not a mindless and childish form of entertainment without any serious consequences requiring scholarly examination? We believe the answer to that question is a resounding "no". We propose that video games are one of the first samples of IT with which children come into contact and can have a profound effect on their acceptance of technology overall. It can be argued that the sooner children come into contact with and accept technology, the more likely they will be to sustain such activity into adulthood.

Interesting cultural aspects related to video games are arising as this form of IT generates interest in research communities, especially when examining the social dynamics of video game players (e.g., real time strategy (RTS) gosus, arcade junkies) and video gaming communities (e.g., role-playing game (RPG) clans, first-person shooter (FPS) sects). Similarly, the recent influx of games with mature content has increased the number of older video game players (Snider, 2002). Moreover, there are observable emotional and psychological effects that video game players experience. For example, some reports suggest that video games with violent themes can desensitize individuals (Violent Video Games, 2000).

Video games have become so popular and pervasive that they are transforming the modern world, and these effects are measurable at the individual, organizational, societal, and even global levels. The sheer economic impact alone of video games cannot be ignored; a recent article reports that the video gaming industry generated $9.9 billion in revenue for 2004 (Richtel, 2005). Finally, video games can be considered a "gateway to computer literacy" for children (DeBare, 1996). This also implies that video games have more of a role in a child's lifestyle than simply mindless entertainment.

Studying video games as they relate to gender and IT is thus a worthwhile endeavor with non-trivial ramifications. Specifically, studying how playing video games relates to gender differences in the IT work profession may provide interesting results because such an inquiry would identify a possible contributor to the gender gap noticed in the IT workforce today. Males have traditionally possessed a strong desire to interact with technology, which we posit is partly driven by increased exposure to video games. Males therefore appropriate artifacts of technology (e.g., computers, wireless, handheld devices, etc.) more readily than their female counterparts. Contrarily, females are being alienated from technology, which we believe is a causal result from their lack of positive video game experiences.

How video games affect the gender gap in IT could be explained in the following manner. The IT profession is considered a male-dominated and male-oriented field. If we include game developers as part of the IT profession, we find little exception to this dominance. Video games are thus designed from the minds of male game developers; Saltzmann (2001) reports that 99% of all game developers are men.

Video games conventionally have had a stronger appeal to males than females. Less than 30% of all video game players are female and the number of "serious" female game players is considerably lower (DeBare, 1996). For example, only 5% of *GamePro* magazine readers are female and only 8% of the buyers who returned product registration cards to Electronic Arts, a leading game design company, are female (DeBare, 1996). As a result, the majority of video games contain an emphasis on overtly male-oriented themes such as gratuitous sex and violence, extreme action, science-fiction themes, mythical fantasies, and sports. Due to this overly male-oriented content of video games, young males are naturally drawn to them. Therefore, we posit that young males have a "fun" or positive interaction with technology, while young females do not. Young males thus have an initial attraction to technology that is driven by video games, and consequently may have a strong desire to seek professions where technology is central to the work (e.g., programming, animation). Conversely, young females who lack this "fun" interaction with technology may miss the attraction, thus resulting in a lack of interest in pursuing a career where technology is essential.

Thus, we propose a research agenda that examines female interest in video games as a method to address the gender gap in the IT profession. We speculate that investigations into the gaming habits and gaming preferences of females can not only provide an understanding of women's interests in video games, but also lead to characteristics that can be emphasized to increase female interest in technology.

BACKGROUND

Much of the literature concerning gender-related video game preferences focuses on negative appraisals of the depiction of women by the gaming industry and its predominantly male design and programming staffs. Research has found that pre- and post-adolescent females are displeased with many of the features in video games. This is most clearly evident in research where avatars, the electronic representation of a player in a video game, are critically examined. Avatars can be graphically represented on a video screen, or consist of sets of textual descriptions including vital statistics such as height, weight, and age. Lois Salisbury, president of Children Now, is quoted in a CNN.com feature (2000, para. 13) as saying, "there is an interactivity, there is an absorption, and the children who are playing are actually assuming different characters [avatars]. That does a lot for identity formation."

Many female interviewees reported that they find much of the content in video games sexist and degrading due a continual display of female avatars as enhanced sexual objects (Cassel & Jenkins, 1998; Saltzmann, 2001; Swanson, 1995; Wilcox, 1996). In a study commissioned by Children Now, the child advocacy group found that in the top ten best selling games for three popular game console systems, female characters were displayed in an "exaggerated and stereotypical manner" (CNN, 2000). Children Now also found that 38% of female avatars were depicted with considerable body exposure (CNN, 2000). Girls tend to not only disdain the prototypical large breasts coupled with an impossibly small waist of female avatars, but also the use of high-pitched giggles, sighs, and whimpers in voice-acting (Cassel & Jenkins, 1998; CNN, 2000).

Body image, while a prevalent topic in today's gaming market, is not the only feature alienating female gamers. One of the more established stereotypes of female characters viewed negatively by female respondents is the "damsel-in-distress" character, such as the tried-and-true "trapped princess formula" used in games such as *Super Mario Brothers* or *Prince of Persia* (Kiefaber, 1998; Saltzmann, 2001). Likewise, in instances where male characters are in need of rescuing, women rarely save them (QuickFacts, n.d.).

Female interviewees cite violence as another detractor in video games. Violent games, such as *Mortal Kombat* or *Quake*, are shunned by females for several reasons, including lack of intellectual stimulation (Wilcox, 1996), repetitive structure of violent behavior (Wilcox, 1996), and aversions to blood and gore (DeBare, 1996). The results of a survey administered to 137 high-school teens by the National Institute on Media and the Family and the University of Oklahoma show that the average teen enjoys a "moderate amount of violence" in video games, "roughly 5 on a scale of 1 to 10" (QuickFacts, n.d.). Unfortunately, this statistic is skewed since it incorporates young males' perspectives as well as their female classmates. When limited to male responses only, the average teen "likes a fair amount of violence", which was determined from an average response of 7 on the same 1 to 10 scale (QuickFacts, n.d.).

Inspired by an article written by a female staff member from GameGirlz.com, Phillipe O'Connor (2000) put forth a biological argument to explain women's deterrence of video games. His work states that feminine instinct directs women away from deriving pleasure from violent games whereas, based on evolution, males may experience satisfaction in such aggression. The argument is further supported by showing the significance of childhood games such as "House" and "Hide and Seek" in the following:

If we accept the fact that playing is a type of animal behavior that evolved to help us survive ... a primarily instinctive behavior, as opposed to learned, then we can move onto the specific topic of male and female play, which dare I suggest, is also largely based on instinct. (The Biological Roots of Gaming section, para. 6)

This article insists that women receive pleasure from personal interaction in a social group, and thus video games containing content similar to soap operas would be successful.

Identification of these factors by researchers has led to the creation of several female-owned and largely female-staffed companies such as HerInteractive, Girl Games, Girltech, and Purple Moon. Even so, a dichotomy exists regarding the success of these companies and video games targeted specifically towards a female audience. Cassel and Jenkins (1998) cite that *Barbie Fashion Designer* sold over 500,000 copies in its first two months, a figure which exceeded sales of so-called male-centered games such as *Doom* and *Quake*, as a positive. In her thesis, *Computers and the Internet: Listening to Girls' Voices*, Dee Dee Wilcox (1996) presents a contrasting viewpoint based on her respondents, stating that games such as *Barbie: Super Model* or *Girls Club* were not appealing since they focused on outward appearance and sexual appeal. Similarly, many girls regard these games as too "girly-girl" (Girls and Video Games, 1999; Hamilton & Hokanson, 1999), or representative of stereotypical, even sexist, viewpoints of male software designers (Cassel & Jenkins, 1998; Wilcox, 1996).

MAIN THRUST OF THE ARTICLE

Two insufficiencies surfaced during our examination of the literature. First, there is an incomplete treatment of the full age range of young females. Much of the research detailed in the previous section focused on young girls, mostly pre-adolescents between the ages of 6 and 12. In fact, the literature reviewed is rather exhaustive in covering this age group. While recent studies have extended attention to high school-aged teens, they lack significant examination of collegiate-aged and older women. Statistics show, consequently, that the gaming age of women has extended well beyond 21 in recent years, especially as technology becomes a more central part of lives (Snider, 2002). Thus, we consider it important that research conducted on this topic include collegiate-aged and older women audiences, presumably females between the ages of 18 and 27 since this would follow the demographic makeup of workers in the IT sector.

Similarly, the literature is "inadequate" in that it does not "sufficiently incorporate different perspectives and views of the phenomena under investigation" (Golden-Biddle & Locke, 1997). There is an extreme emphasis in many sources on the negative aspects of video games that have led females away from video game playing. Additionally, there is disparity over preferences, particularly those voiced by proclaimed feminists (Cassel & Jenkins, 1998) against those of female-owned and operated gaming companies and even the females interviewed and observed in some articles (Bergman, 1998; Wilcox, 1996). Several articles (Buchman & Funk, 1996; DeBare, 1996; Girls and Video Games, 1999; Kiefaber, 1998; Saltzmann, 2001) attempted to explain what females preferred, but most often strayed from the features that could build a "pro-female" game, and focused upon what was perceived as poor with current designs. This article asserts that research should seek the characteristics of video games that women prefer and build upon those preferences in a positive manner.

We focus the remainder of discussion using the following research question: *What features/characteristics of video games are most likely to appeal to a female audience?* This question is intended to drive a research program to discover and be able to describe the specific features and characteristics that attract females to video games. We propose that such a study should be performed qualitatively, rather than quantitatively, for three reasons. First, the research question seeks to understand the meaning behind the quantitative data consistently cited in the literature. As detailed in the previous section, females are an underrepresented group in the video gaming industry, both as players and designers. The reasons behind this lack of representation are complex and require a deeper level of analysis than quantitative methods afford. Our suggested research program seeks to understand the features of video games that women find most appealing and engaging. Thus, the data that this research would obtain will not be numerical in nature, but rather richly descriptive and qualitative in nature.

A second rationale is the amount of uncertainty concerning female video game preferences. Such game features are not well understood, as we have shown in our discussion of the literature. The disparity and conflict over what game features women find most appealing creates ambiguity. Additionally, what women find appealing about video games is not clearly documented, though there is considerably more literature concerning this phenomenon than we initially anticipated.

Finally, we suggest approaching this research with an emic, or insider, perspective. Through this research, researchers will delve deeper into the mindsets of female video game players and discover what women desire in a video game. The research seeks the reasons and influences for why women do or do not play video games. Additionally, the research focuses on the discovery of what features alienate women from playing video games and identification of the characteristics that increase their desire to play. Previous experience and the knowledge level of video games by researchers will affect perspective and determine whether qualitative methods are appropriate. However, we feel that researchers should feel comfortable immersing themselves in the research due and possess a certain amount of familiarity and interest with the research topic in order to be successful.

FUTURE TRENDS

We recommend two research methods for studying this phenomenon: a case study involving collegiate-aged women and an ethnographic study (if possible) of female video game players. Additionally, research instruments such as surveys and semi-structured interviews, as well as participant observation opportunities, would provide researchers with rich, descriptive data. Table 1 details possible survey and interview questions appropriate to this research initiative. These instruments would also allow researchers to immerse themselves in the female video gaming culture. For instance, the semi-structured nature of the interview allows researchers to ask additional questions of participants, particularly when an interest in a particular question or certain topic is noticed. As an example, suppose one participant mentioned that she liked playing the game *Tomb Raider*, which features the buxom lead character Lara Croft, in response to an interview question (see Table 1). The researcher could then inquire about the participant's feelings regarding the design of the avatar. Having such a flexible format allows researchers to more readily gather finer grained information from a participant.

The information we regard essential for discovering the video game preferences of women is gaming history, current gaming frequency, favorite video games, and the features that are most appealing about those games. Gaming history and current gaming frequency present preliminary background about a person's gaming habits. We define gaming

Table 1. Possible survey and semi-structured interview questions

Survey Questions
• *Have you ever played a video game?* • *Do you currently play video games? If so, how often?* • *What are your favorite game titles?* • *What games are you currently playing?*
Interview Questions
• *Have you ever played a video game?* • *If so, what are your all-time favorite video games?* • *How often did you play in the past?* • *Do you currently play video games? If so, what games?* • *How often to do you play?*

history as the types of video games the person played in the past and how often they played video games. Subsequently, current gaming frequency is the amount of time a person currently plays video games. Thus, these two factors together provide a clear picture of overall gaming habits for a person. For example, the information that a female who has played one video game in the past, played it sparingly (gaming history), and is not currently playing any video games (current gaming frequency), yields that this person has had little exposure to video games and/or may dislike video games in general. Conversely, a female that has played a large number of video games in the past, played them at a high frequency, and continues to play video games regularly shows that this individual has an avid interest in video games.

Knowing a person's favorite video game allows the researcher to examine the characteristics that are common among them. Knowing interviewees' favorite games allows us to uncover the qualities and features of video games that appeal to them. Therefore, even though the features of video games that women prefer can be sought by asking straightforward questions in a survey or interview question, popular features, which may be more subtle, may be drawn out by examining the person's favorite games.

CONCLUSION

Past studies have attempted to generalize the video game preferences of women. We feel, however, that female interests in video games are too divergent to be generalized. In fact, we suggest the opposite of what was discovered in the literature, namely, that the video gaming industry needs drastic transformations if it is to appeal to women. We recommend that qualitative research methods be employed to uncover the video gaming preferences of collegiate-aged women. By performing case studies, ethnographic observations, and conducting surveys and semi-structured interviews, we believe that the gaming habits and gaming preferences of females can be revealed. Video game developers should treat women as individuals, rather than a group when it comes to addressing their interests. Perhaps only then can women feel included in the video game community.

KEY TERMS

Avatars: Graphical representation of a user in video games, usually associated with the main character or player.

Console: A dedicated electronic device designed to play video games.

First-Person Shooter (FPS): A video game that is played from the first person perspective (e.g., looking out of the eyes of the main character). To achieve the "shooter" aspect, the character usually wields some type of weapon.

Gosu: Refers to a person with great skill in video games, especially RTS games.

Real-Time Strategy (RTS): A type of strategy game that progresses in "real time"; that is, it is continuous rather than turn-by-turn. The word *strategy* originally referred to planning at the level of armies and squadrons rather than giving orders to individual units or persons.

Role-Playing Game (RPG): A type of game where players assume the roles of fictional characters and involve interactive and collaborative storytelling; typically take place in fantasy/science-fiction settings.

Video Games: A game composed of a computer-controlled virtual universe that players may interact with in order to achieve a goal (or set of goals). *Video game* is frequently used as an umbrella term for interactive game software.

A

Age, Gender, and Cognitive Style Differences in IS Professionals

Michael J. Gallivan
Georgia State University, USA

INTRODUCTION

There is a long tradition of research on IS professionals that has examined potential gender differences between men and women, beginning with early studies by Igbaria and his colleagues (Guimaraes & Igbaria 1992; Igbaria & Chidambaram 1997; Igbaria & Siegel 1992). While these and many subsequent studies posited differences between men and women IS professionals, very few differences have been found—particularly for variables that are commonly studied: job satisfaction, turnover intentions, organizational commitment, and stress. I first summarize the results from many survey studies published in leading IS scholarly journals, as a way to frame my research on the adaptation of IS professionals to innovations in work practices. Then I summarize my program of research examining demographic variables, including age, gender and cognitive style differences as explanatory variables for a range of outcomes among IS professionals.

LITERATURE REVIEW

Research on Gender, Job Satisfaction, and Job Turnover

Numerous studies have consistently sought—and failed to find—gender-related differences in job satisfaction, turnover intentions, organizational commitment, and other job-related attitudes. One difference that has been frequently noted in studies of IS professionals is that women, in general, have fewer years of experience in the IS profession—not surprising, considering the delayed entry of a sizeable number of women to the IS field (Baroudi & Igbaria, 1994/1995). Various comparative studies have reported that the average job tenure of women IS professionals is less than for men, and that women respondents are younger than their male counterparts (Sumner & Niederman, 2003/2004). However, with the exception of a few studies of job stress among IS professionals, most studies that have posited gender differences in job satisfaction, turnover intentions, and organizational commitment have come up "empty handed." One recent study, in fact, examined 34 potential differences related to the career history, salaries, job search behaviors, and job satisfaction of IS graduates in the U.S., finding surprisingly few differences in the career experiences of men and women. The only differences noted were that women were more satisfied with their pay than men (despite women's lower salaries), and that, when they did change jobs, women took longer, on average, to actually leave (141 days for women vs. 75 days for men). All other variables were similar for the men and women, prompting the authors to remark that employees seem to "experience an even playing field in the IS profession, regardless of gender" (Sumner & Niederman, 2003/2004, p. 36).

While it is widely believed that women IS employees have higher turnover rates than men, no empirical study has documented such an effect. The one study that found a significant difference in turnover intentions between men and women reported that "a woman is more likely to estimate *longer* continuing employment at her firm than a man" (Baroudi & Igbaria 1994/1995, p. 198).

Studies of Job Stress

While there has been a growing literature on job stress among IS employees, few consistent gender-based differences have been found. Of more than a dozen studies that have examined job-related stress among IS professionals, however, we note that half of the studies neglected to conduct *any* gender-related analyses (Baroudi, 1985; Igbaria, Parasuraman, & Badawy, 1994; Sonnentag, Brodbeck, Heinbokel, & Stolte, 1994)—in many cases, even neglecting to mention what proportion of the sample was women (King & Sethi, 1997). Of the few studies that reported what proportion of the sample was women and provided at least a rudimentary analysis of gender differences, most researchers found no gender differences in job stress (Guimaraes & Igbaria, 1992; Igbaria & Chidambaram, 1997; Moore, 2000). One study of IS workers in Singapore, however, identified differences—with women reporting higher levels of work-family conflict, as well as greater stress arising from interactions with supervisors and coworkers (Lim & Teo, 1999). Another recent study of U.S. workers also found that women reported higher levels of job stress (Sethi, King, & Quick, 2004).

Studies of Job Performance

While many studies of IS professionals have examined affective constructs (such as job satisfaction and stress), few studies have examined job performance—and the few studies of job performance have generally neglected gender (Rasch & Tosi, 1992; Wade & Parent, 2001/2002). While most of these studies have reported the proportion of women in their sample (and nothing more), some studies have neglected to report even this (Clark, Walz, & Wynekoop, 2003). One study that conducted a gender comparison of supervisors' ratings of IS workers' performance found no gender differences (Igbaria & Baroudi, 1995). A second study found that women IS workers were more *conscientious* than men and that conscientiousness was, in turn, strongly related to two dimensions of IS professionals' performance (Witt & Burke, 2002). The latter study examined the relationship between performance and the "Big 5" personality factors often studied in psychology research.[1]

MAIN THRUST OF THE ARTICLE

Given this body of prior literature and my own interest in studying how knowledge workers adapt to using new technologies in their jobs, I have been engaged in ongoing research to understand what factors shape individuals' abilities to adapt to using new technologies. My research examines whether demographic variables (e.g., age, gender, job tenure) or cognitive style differences explain IS professionals' ability to adapt to technological innovations and related changes in work practices. Over the past decade, there have been numerous technological innovations that have been introduced in the work of IS professionals and many early writers posited that demographic variables—namely age—would explain the difference between those employees who successfully adapt to these changes vs. employees who do not adapt well. While researchers in this area rarely mention gender as a factor that affects IS professionals' ability to assimilate change, scores of studies appearing in IS trade magazines posited age as a factor—often labeling older IS workers as "old dogs" incapable of learning new tricks (Ambler, 1994; Betts, 1992).

I conducted a longitudinal, mixed-methods study during the mid-1990s to understand how organizations were implementing one popular innovation that changed the practices of IS workers at that time (client/server development). In my study, I examined the implementation processes in four large organizations in the northeastern U.S., combining interviews of IS managers, IS employees, HR managers and training specialists with surveys of IS employees and managers. Interviews in the four firms showed that companies used a broad range of approaches to implementing client/server and "reskilling" their IS employees. These approaches ranged from firms that conducted a highly-structured, centralized initiative to reskill employees—as occurred in one financial services organization (Gallivan, 2001a) to another firm that essentially paid "lip service" to the notion of reskilling their employees to perform client/server development. The latter organization, while promoting the need for employees to "take charge of their careers," was actually in the process of drastically reducing the size of their IS workforce through voluntary lay-offs and other involuntarily measures (Gallivan, 2001b).

The two other firms followed different approaches—with one firm simply hiring new employees with the requisite client/server skills rather than retraining current employees, and the other firm expecting its employees to maintain their technical currency mostly in their "spare time." Not surprisingly, many of these employees in the latter firm (an engineering firm) emphasized the long hours they had to spend to keep up (Gallivan, 2003a). One of these employees referred to his approach to learning client/server as "baptism by fire," while another explained her approach as:

The brute force method: dive into the books and don't come up for air until the final page. Immediately apply [what I've learned] until everything clicks!

In another case, an IS manager from the engineering firm explained which employees succeeded:

We hire good people, throw them in a slot, and get the work done. We see which ones [rise] up. One example was a woman who had her nose in front of the computer terminal all the time, working on it. We had to throw her out [of the building] at night.

In both my interviews and subsequent survey research, I sought to identify whether individual demographic factors (e.g., age, gender, and job tenure) could explain employees' ability to assimilate client/server development–and their attitudes toward it—or whether personality and cognitive style attributes were the underlying factors that shaped employees' outcomes. In the interviews I conducted, neither age nor gender was mentioned by my informants as an explanation for employees' ability to adapt to using client/server. Rather, they mentioned a host of factors—ranging from having experienced other skill transitions in the past to cognitive style attributes. I examined these three cognitive style attributes in my survey—*tolerance of ambiguity* (Gallivan, 2004), innovativeness, and personal *resilience* (Gallivan, 2003b).

My survey examined five sets of outcome variables as indicators of employees' ability to adapt to client/server development and associated changes in work practices. These included (1) attitudes to the client/server innovation itself; (2) employees' job satisfaction; (3) job stress; (4) turnover intentions; and (5) the supervisor's evaluation of employee's job performance. I examined job performance along several dimensions that had been reported in prior studies (Goldstein, 1988)[2]. My employee and manager surveys (based on two of the original firms) showed that gender was related to only one of these outcome variables at conventional levels of statistical significance: job stress. Women employees reported higher levels of job stress, as a whole, and especially in the engineering firm that expected them to "reskill" themselves largely on their own time (Gallivan, 2003a). In fact, women in this firm reported much higher levels of stress than all other employees; moreover, both the men and women in this firm reported insufficient supervision—revealing the belief that they were expected to do too much on their own (Gallivan, 1997).

Other than this difference in job stress, there were no other statistically significant gender differences for any of the other outcome variables—which is consistent with prior studies of IS professionals that examined gender. There was a slight trend in my survey data for women IS employees to report higher levels of job turnover intentions (which was weakly significant, at $p < 0.10$), but this result appeared only after statistically controlling for employees' job satisfaction. I interpret this finding to mean that after controlling for employee job satisfaction (which is the *primary* determinant of job turnover intentions); women IS professionals were slightly *more* likely to consider leaving than men. There was no difference in the level of job satisfaction for men or women, however. There was some anecdotal evidence (based on responses to general, open-ended questions at the very end of the survey) that the women's slightly higher turnover intentions were due to their concerns about childcare. Several optional, open-ended comments added by some women suggest such an explanation (although it is impossible to know for certain whether this accounted for the women's slightly higher turnover intentions):

With regard to [my plans for] leaving this company, I'd like to clarify that I sometimes think about leaving to become an independent consultant. I already have ... the skill set to work on my own. This is attractive to me primarily because I'd like to cut back on the number of hours I work to spend more time with my daughter; however, I haven't done this yet because of the benefits I receive here.

Regarding the question of leaving my employer, I would very much like to work closer to home. The convenience of a workplace is very desirable to me, and working [here] is not very convenient.

In summary, my survey data showed that gender had a statistically significant relationship with job stress only (which was exacerbated in the engineering company), but no differences in the other four outcome variables. In contrast to the general lack of gender differences, I found that employees' age was inversely related to their supervisors' evaluation of their technical skills, but age was not related to the other dimensions of job performance (business knowledge, job attitudes, and communication skills). Based on my results, there appears to be some truth to the conventional wisdom that younger employees are more technically adept than their older counterparts. However, it is also worthwhile to consider that perhaps IS supervisors "buy in" to the notion that older workers are less skilled technically, since the job performance data were based on subjective evaluations from supervisors, rather than objective measures of employees' skills or work outputs. Moreover, the fact that there were no other age-related differences on other dimensions of performance raise questions about the conventional wisdom that older IS workers are "dinosaurs" (Betts, 1992) or "old dogs" (Ambler, 1994) who cannot adapt to new technologies. I even found that supervisors' ratings of employees' business knowledge were *positively* related to how long employees' had worked in the IS field—thus suggesting that more experience on the job is an asset—not a liability—for IS workers.

In examining the three cognitive style variables (tolerance of ambiguity, innovativeness, and personal resilience), I found that all three attributes were positively linked to employees' job satisfaction but all were unrelated to gender—as I had hypothesized. To my surprise, however, none of these cognitive style attributes were positively associated with job performance. In fact, personal resilience was *inversely* related to supervisors' evaluations of employees' business knowledge (Gallivan, 1997, 2004). This was a startling finding, and one that I have struggled to interpret. Yet the interpretation is revealing: employees' stock of business knowledge increases with their length of time in the company and in the IS field; however, more resilient employees have a greater "appetite for change," and thus, the highly-resilient employees are less likely to remain in a given job than their less-resilient peers. Thus, IS employees who are highly resilient are more satisfied in a given job but, in part, because they are so attractive to other employers, they tend to be lured away to new job opportunities (Gallivan 1997). This reflects a "double-edged sword" to having employees who are highly resilient: they may not remain in a given firm as long and hence, may not amass as much knowledge of the firm's business.

CONCLUSION

To summarize, I found four results for the demographic variables that I studied: first, gender was related to job stress, with women reporting higher levels of stress; second, age was inversely related to supervisors' ratings of employees' technical skills; third, all three cognitive style variables were positively related to employees' job satisfaction following adoption of client/server; and fourth, personal resilience was inversely related to supervisors' ratings of employees' business knowledge. While my findings are consistent with prior research in terms of the general *lack* of differences between men and women IS professionals on most outcomes (e.g., job satisfaction, job performance, turnover intentions, etc.), the higher levels of job stress that I found for women IS professionals were consistent with two recent studies (Lim & Teo, 1999; Sethi, King, & Quick, 2004).

FUTURE TRENDS

It is not known whether *all* IS jobs are more stressful for women IS professionals, or whether this effect is only present when women perceive themselves to be token workers within a "male-dominated majority culture" (Kase & Trauth, 2003, p. 1559). Some evidence for the greater incidence of stress among professional women who work in male-dominated fields has been documented by management scholars in a range of industries (Gardiner & Tiggeman, 1999). Although my results cannot shed light on this question, an interesting question for follow-up research is whether higher levels of job stress among women IS professionals disappear or become less problematic in firms that have a large proportion of women IS professionals (or women employees, in general). While the issue of turnover as a function of the proportion of women employees has been examined by management researchers in other industries (Elvira & Cohen, 2001)—with mixed results—I consider this to be a worthy topic for follow-up studies by IS researchers.

KEY TERMS

Client/Server Development: An approach to developing software applications, introduced in the 1990s, that uses PCs with graphical user interfaces and specialized application development tools to replace conventional programming with third-generation languages (3GLs), such as Cobol or C.

Resilience: The psychological attribute of being able to endure stressful life events.

Reskilling: A term, popularized in the early 1990s, to describe IS employees learning new skills.

Tolerance of Ambiguity: The ability to feel comfortable in unfamiliar, new, or ambiguous situations.

Technological Innovation: A new tool or software development methodology.

ENDNOTES

1. The "Big 5" personality variables are conscientiousness, agreeableness, extroversion, emotional stability, and openness to experience. Witt and Burke (2002) found that women were more conscientious which was, in turn, related to supervisors' ratings of employees' relationship management skills and quality of technical documentation.
2. I examined four performance facets: technical skills, business knowledge, communication skills, and job attitudes.

Analyzing Gender Segregation in Computing

Leena Ghoshal
New Jersey Institute of Technology, USA

Katia Passerini
New Jersey Institute of Technology, USA

INTRODUCTION

Gender appears to be a fundamental category for ordering and classifying social relations in the world (Evans, 1994). The first thing we are told about a newborn is whether it is a boy or a girl. Gender as defined by Acker, (1992, p. 250) is a "patterned, socially produced distinction between female and male, feminine and masculine" and is a key concept for understanding the degree of male and female participation in any field, including information systems. This review aims at developing an understanding of some of the reasons that underlie (a) the gender segregation that exists within the broad, interrelated fields of computing (information systems (IS), information technology (IT), and computer science (CS)) and (b) the declining levels of female participation in the computing industry across the continents. The three computing disciplines (IS, IT, CS) and the computing profession clearly appear gender segregated, with a male dominance at all levels. As Booth (1999) noted, while one of the first software ever written for a machine was produced by a woman—Ada Lovelace in 1840, it is a male, Charles Babbage—the inventor of the difference calculating machine—that is generally accepted as the founding father of computing. Booth concludes: "And that, in microcosm, has been how the IT industry developed over the next 160 years—a combination of rapid technical advances leading to skills crisis while half the nation's workforce has been routinely overlooked" (p. 47).

BACKGROUND: THE GENDER DIVIDE

Even if recent data and trends show a slightly improved scenario, the number of women in computing still remains a minority. Women participation rates in the IT sector have fluctuated somewhere between 19% and 22% during the 1990s (Robertson, Newell, Swan, Mathiassen, & Bjerknes, 2001), whereas since the early 1990s the overall female participation rate in the labor force has never fallen below 45% (Panteli, Stack, Atkinson, & Ramsay, 1999).

Women continue to be segregated both horizontally and vertically, both in academia and business. In terms of horizontal segregation, women are found working much more often in what are considered to be "softer" aspects of this profession, for example, in sales, marketing and support functions such as help desk and customer service. These areas require superior interpersonal skills and women tend to be gender-stereotyped as almost naturally having such skills (Wilson, 1999). Men continue to dominate in technical areas such as analysts/programmers (Panteli et al., 1999). In terms of vertical segregation, computing is still dominated by men and the imbalance is more striking on the higher levels of the corporate hierarchy (Candee, 1997). Candee provides a number of examples to illustrate this vertical segregation. For example, in the Society of Information Management (SIM), a U.S. organization of senior IT executives, only 195 of its 2700 members were women in 1997. This segregation is reflected in continued wage differential (Panteli et al., 1999) as the average compensation does not rise equally. According to a CRN (2004) salary survey, solution providers handed out bigger raises to male managers than to their female counterparts. In 2003, wages grew an average 7.7% to U.S. $101,000 for men, while compensation for female managers grew an average of 2% to U.S. $87,900. Nevertheless, the gender gap among IT managers was found to be smaller than in most U.S. industries. The government accounting office (GAO) reported that women in 2000 were being paid 80 cents for every dollar men were paid for similar positions, a gap that has remained relatively steady over the past two decades (CRN, 2004). In contrast, solution providers were paying their female managers 87 cents for every dollar paid to the male managers. The 2004 CRN report also noted that while large IT companies tend to pay better than their smaller counterparts, when it comes to raises, smaller companies tend to be more generous.

Male dominance in the business areas of computing is similarly reflected in academia both in teaching and student enrollment levels. In the teaching area, for example, in the 1998 European Conference on Information Systems (ECIS), only 35 of the 300 participants were women. Female students enrollment rates in computer science courses across the U.S. and Europe at all levels (undergraduate, Masters, and PhD) declined quite dramatically throughout 1980s and 1990s (Lander & Adam, 1997; Panteli et al., 1999). The number of women enrolling in computing courses fell from a high of 28% in 1978, to 13% in 1995, and down to 9% in 1998 (Booth, 1999). In other words, the computing discipline continues to mainly attract men to educational courses and, subsequently, to more senior technical positions in this industry.

This situation is distinctive of the computing field and appears to be the core of the problem. While female participation in computing is at a decline in many other academic fields, women representation in other disciplines has steadily increased and is becoming more reflective of overall population patterns. For example, in the UK, the number of women across all academic disciplines constitutes almost one-half of the undergraduate population (Robertson et al., 2001). Many traditionally male dominated academic disciplines—such as medicine and veterinary sciences—are witnessing significant increases in female participation rates (Grundy, 1996).

In view of the previously mentioned findings, and in an attempt to better understand the reasons of this "gender divide," it is worthwhile to examine the specifics of gender segregation in computing.

ANALYZING GENDER SEGREGATION IN COMPUTING: A REVIEW OF KEY ISSUES

The gender-based segregation in IT could be considered a reflection of the broader pattern of horizontal and vertical segregation that exists in society, rather than anything specific to computing. This presumption frees the professional community from any responsibility to take action to promote change. If we are to encourage women to enter the field of computer science, information technology, and management information systems, we should focus on promoting a debate within the field to stimulate the necessary changes. Understanding the drivers and key examples of gender segregation is a pre-requisite to initiating a dialogue.

Techno-Hazing (or Overt Gender Bias)

In some cases, the segregation of men and women within the computing profession is a result of blatant/overt gender bias. For example, DiDio (1997) interviewed a number of women in Silicon Valley and found numerous examples of women still grappling with problems of being assigned manual tasks, whereas their male colleagues with similar backgrounds were given a "choice" of assignments. DiDio coined the term "techno-hazing" to describe this phenomenon of gender bias. Techno-hazing refers to the bias that results from the assumption that women cannot be technically competent; and even when qualified, they are given lower complexity jobs or are supervised more closely. When blatant discrimination is visible, there is room for fairly direct actions, such as legislations. Many companies and Universities already have Equal Opportunities Policies that attempt to go further than simply complying with the legislation. For example, many Universities require employees across the organization to take sexual harassment and sensitivity classes (and they require that all employees be certified in such courses).

Latent (or Covert) Bias

However, while initiatives such as those described above can help to combat direct discrimination, they do little to eradicate indirect, subtle, and insidious discrimination. This indirect gender bias is not really seen or acknowledged. Therefore, it is more difficult to address. As Meyerson and Fletcher (2000) observe, gender inequity across the industry has not vanished, but has simply gone underground, perpetuated "in a plethora of work practices and cultural norms that only appear unbiased" (p. 127). Covert discrimination continues to take place because of gender-biased beliefs about jobs, tasks, roles, and people that are communicated and indirectly reinforced continuously within organizations (Wilson, 1997).

There are three processes perpetuating these covert biases: (a) the marketing and pedagogic design of IT and IS; (b) the exclusion of women from important and influential networks; and finally, (c) the difficulty in gaining legitimacy as experts in IT and IS fields. Each of these processes is briefly described as follows.

a. **TheMarketing and Pedagogic Design of IT and IS:** Part of the problems in recruiting female graduates relate to the course content and how it is presented and taught. As Booth (1999) comments: "Few women yet see IT as a desirable profession, which is a reflection of its techie image." While the computer itself displays no gender bias, the computer culture and the socially constructed discourse that surrounds computing is not equally neutral. Wilson (1997) suggests that there is a legacy in computer cultures of masculine images of competition, sports and violence, enhanced with a discourse that resorts to using phrases such as "killing a job," "aborting a program," "work-benches," "tool-kits," "drives," "engines," and so forth that are commonplace jargon with masculine connotations. How can we begin to address the dominant socially constructed masculine world of computing if technical courses display computing as a "man's job"?

b. **The Exclusion of Women from Important and Influential Networks:** While female student numbers are small and appear to be falling, there is an even greater problem in terms of women actually working in the profession in industry or academia. According to a study entitled "Opportunities and the Gender Pay Equity in New Economy Occupations" issued by the White House Council of Economic Advisers in May, 2000 (Bentsen, 2000), it was noted that women in the U.S. make up only 29% of workers in IT occupations, compared with 47% in the general workforce. The White House study also found that women in IT earn an average 60% more than women in other occupations. Even though the opportunities are there, female IT share in the workforce fell from a peak of 40% in 1986 to a current low rate of 29%. Robertson et al (2001) noted that across University computing departments in the UK, women constituted only 13.4% of lower level teaching and research posts, falling to 6% at senior levels. About 18% of computing departments did not have any women among the faculty (Grundy, 1996). Since these departments are responsible for the pedagogical design and marketing of computing courses, the lack of women, particularly in influential positions, must be considered a critical issue. If there are too few female academics within the field, their presence and influence within important powerful networks in the computing arena will also be minimal (an example was the 2000 ECIS conference attendees' distribution).

   Networking has always been recognized as a crucial element in career progression. Because of such poor representation, it becomes difficult for women to affect changes to the current status quo. As Hemingway (1995) and Meyerson and Fletcher (2000) noted, women actually encounter a "Glass Door" on entry to the international computing community rather than encountering the better known "Glass Ceiling" as their careers progress.

c. **Legitimizing Claims to Knowledge:** Finally, legitimizing claims to knowledge- legitimacy as a female expert in the computing field is yet another issue centering on gender related segregation. A number of studies have shown that successful completion of computing courses in college is only a beginning.

Women in the computing industry often encounter further problems associated with patterns of communication between genders that can make some aspects of IS/IT projects or research problematic. The academic literature presents examples that when attempting to negotiate access to data in organizations, a female researcher is confronted with communication barriers (Robertson et al., 2001). Robertson states that these barriers did not apply in the same way to their male research fellows, perceived as more reliable content exerts even when they were less qualified than their female counterparts. Robertson also found that women in IT face fewer problems in Sweden than in the UK. Institutional differences in training and education, the perception of IT management in these nations as well as national differences in managerial attitudes towards university-based research is responsible for such disparity.

Women's Attitude Towards IT/IS

In a two-year study released in April 2000 entitled "Tech-Savvy: Educating Girls in the New Computer Age", the American Association of University Women (AAUW) suggests that the vast majority of girls and women hate information technology. The AAUW study indicated that girls are not necessarily computer phobic but they prefer occupations that are more socially inclined. Most of the women are unaware of the social implications of computing and more creative career paths within IT are not pursued. The academic literature presents numerous studies related to various aspects of women involvement in management information systems. Dattero, Galup, and Quan (2004) noted that most women in the MIS/IS/IT field work in mainframe systems and COBOL programming, whereas newer technology areas like Oracle, JAVA, and C++ are dominated by men. Women in MIS focus more on reporting functions rather than engineering new ones. In studies conducted on 80 MBA students (52 men and 28 women), Hartzel (2003) found that males and females differ in their self-efficacy levels of software use. In the post trials, there was an overall increase in the perception of self-efficacy both among men and women. However, men tend to have significantly higher self-efficacy (a mean pretest score of 4.89) as opposed to women (mean score of 4.64). Supporting self-efficacy is important because it affects one's willingness to invest efforts into purchasing, learning, and using specific software applications.

FUTURE RESEARCH AND RECOMMENDATIONS

The age-old arguments of physical weakness which led to lower payments for women in manual (labor) jobs do not have any basis for such inequities when it comes to the field of IS, as computer related tasks are not managed through physical force. Has this led to decreased discrimination in employment rates, compensation, promotion, and training for women compared to her male counterpart? Based on the review conducted in this article, it does not seem to be the case. The old gender-divide survives across nations. The UK, Scandinavian countries (Sweden) and the U.S. are just some of the economies analyzed. The review still points to the fact that women are under-represented in the field of IS, whether in the academic or business areas. In order to understand the overall gender issues in computing, considerable attention needs to be given to the interrelationships that exist between communication processes, social networking, and legitimizing claims to knowledge overlaid by gendered-powered-relations.

This discussion opens a number of suggestions for future research and provides some recommendations.

FUTURE RESEARCH NEEDS

Communication is essential for understanding gendered relations which are formed and affected through socialization and mutual interactions (Newell, 1999). Gendered relations of power within organizations and academic disciplines are reproduced through communication networks and interactions. Exploring the connections between communication practices and the underlying power structure might help understanding the patterns of overt and covert discrimination.

Studying the reasons behind the lower female representation in MIS is particularly important in view of a collapsing birth rate in the developed world (also termed "collective national suicide" by the renowned thinker of management studies, Peter Drucker) (Drucker, 2001). In the next couple of decades, there will be a decline of skilled workers in every industry, including the field of IT/IS. This being the case, it becomes important to be prepared to deal with the severe labor problem that may arise. This implies empowering the entire labor force, including the women currently excluded from the field, to take a more active role in knowledge capturing, maintenance and creation.

Finally, technology has enabled human beings to work through telecommuting. Physical distances have been rendered meaningless. Women can finally attempt to reconcile an ideal career path, which provides flexible hours and working from home, with a number of household and childcare responsibilities that still affect their lives even when they are part of a shared commitment and distribution of family responsibilities. Sue Rosser (Rosser, 2003) conducted a longitudinal survey contacting the POWRE Awardees (Professional Opportunities for Women in Research and Education), an NSF program that funded tenure-track women engineers and scientists at large universities. She contacted the awardees first in 1997 asking what significant issues they faced as women scientists and engineers. Nearly 63% of respondents singled out "balancing work with family responsibilities" as their biggest challenge. She repeated the survey with POWRE awardees in 1998, 1999, and 2000, and found even greater consensus—73 to 78% of respondents said that balancing career and family was their major problem.

The questions on how to reconcile the conflicting needs of being part of a physical network with the needs of obtaining a work-life balance (through disconnecting from the same face-to-face network) still remain open.

RECOMMENDATIONS

Computer science should be presented as a field that is interdisciplinary and focuses also on a social purpose. Stimulating interest and awareness in the IS/IT/CS curriculum across a far more diverse range of individuals is likely to be the most successful strategy for encouraging gender mix. A radical redesign of computing courses is highly recommended. For example, offering combination of group dynamics, and even home-science courses with IT courses would be a good mix to attract women to a computer science curriculum. The London School of Economics (LSE) has been able to increase the number of women enrolling in computing courses by introducing home science across programs. By changing the computer science courses and the admission procedures, Universities could replicate Carnegie Mellon's success in increasing the percentage of women entering the School of Computer Science from 7% in 1995 to 42% in the year 2000. The debate about serious gender-unbiased curriculum changes has yet to be opened.

KEY TERMS

Covert Discrimination: (Usually negative) behavior manifested to make distinction based on some external characteristics of an object or person, usually in a negative way**.**

(Gender Defined) Horizontal Segregation: Can be understood as separation of women work force from the men in terms of the type of work which requires less technical skills**.**

(Gender Defined) Vertical Segregation: Separation of women work force in terms of low paying, low ranked jobs which involves relatively low decision-making powers in an organizational context.

Gender Divide: Can be defined as an unseen boundary that exists between men and women in terms of the overall differences in their attitudes, habits, preferences and interests.

Glass Ceiling: Following the definition of the Germany's Gender Research Group funded by the German federal government, the "glass ceiling" phenomenon is the invisible but nonetheless rigid barrier that blocks women's access to leading positions whereby women can advance in an organization, but only to a certain point, usually in middle-management, not to upper management or administrative roles.

Home Science: The study of home economics and the relation of the home to the community. It includes many aspects of domestic science, parental education, consumer education, and institutional management (food and nutrition science, clothing and textiles, household economics, hygiene, institutional management and dietetics).

Self-Efficacy: A measure of one's confidence in mastering new challenges. When self-efficacy is high, one believes a high probability exists that one will be successful; while low self-efficacy suggests a limited belief that one will be successful in accomplishing an objective.

Techno-Hazing: Refers to the bias that results from the assumption that women cannot be technically competent; and even when qualified, they are given jobs that lower complexity jobs or are supervised more closely.

A

Approaches to Conceptualising Gender

Darryl Coulthard
Deakin University, Australia

Tanya Castleman
Deakin University, Australia

INTRODUCTION

When people refer to gender issues in information systems, they draw on an implicit understanding of what this means, but may be unaware of the history of the concept of gender or the theoretical debates that surround its development. A thorough understanding of the conceptual and theoretical issues can, however, add much to the quality of research on the gender patterns that are observed in attitudes to and usage of information technologies and in organisational practices. Similarly, a good conceptual understanding will benefit those seeking to launch practical initiatives, including increasing women's access to and involvement with information technology. By building on the work of others, especially in the fields of psychology, sociology, women's studies, and political theory, information-systems researchers will avoid the conceptual pitfalls into which others have fallen.

The term gender usually refers to the socially acquired characteristics of men and women. It is distinguished from sex, which has come to be defined as biological characteristics. We now conventionally use the term gender as a variable in empirical research, although this is simply dichotomised into male or female and thus is really used as a proxy for sex. This distinction between sex and gender arose as a result of debates about gender issues in Western society generally, and with the development of feminist thought in the late 20th century, gender is now widely acknowledged as a key structural principle in society and as a topic of study in its own right (Chafetz, 1997; Tong, 1989; Weedon, 1999). In this article, we briefly discuss the issues underpinning the concept of gender and how this concept has developed.

BACKGROUND

The Rise of Gender as a Concept

Until the mid-20th century and the rise of feminism, gender was not the topic of serious academic discussion. In fact, the term was rarely used. Most traditional social theories simply assumed that conventionally understood differences between men's and women's experiences were the result of their respective innate characteristics and did not require any theoretical explanation. Traditional social theory accepted the view that men and women were natural categories with different behavioural and psychological dispositions (West & Zimmerman, 1987).

Public debates about women's roles gathered strength from the 1960s (second-wave feminism), and writers began to distinguish sex (the immutable biological component of human life) from gender (socially acquired characteristics of the two sexes; Eisenstein, 1984; Millett, 1971). This distinction focused attention on gender as the result of arbitrary and oppressive social practices and strengthened the critique of naturalistic or biological explanations. As social explanations for these phenomena gathered impetus, biologically based explanations were also more clearly articulated.

MAIN THRUST OF THE ARTICLE

Biologically Based Explanations of Gender

Biologically based explanations vary, but the most influential have come from sociobiology (Wilson, 1978) and its recent successor, evolutionary psychology (Pinker, 2002; Wright, 1994). Both approaches argue that evolutionary adaptation has led to behavioural differences between the sexes. Highly complex behaviours were attributed to evolutionary development rather than to social learning and social influences. Versions of these theories often find their way into explanations for behaviour in the popular media, typically to explain courtship, sexual, or reproductive behaviours. Biologically based explanations for the lower number of women in mathematics and computing argue that the sexes have different natural predispositions and innate skills. This approach does not recognise that this is a “complex and multi-faceted problem” with clear social forces at play (Gürer & Camp, 2002, p. 124). Such *biologically reductionist* explanations are, at base, ideological and are used to justify social inequalities (Montagu, 1980; Sayers, 1982).

Steven Jay Gould (2000) outlined a number of reasons why such biologically reductionist accounts are flawed. These include the following:

- The lack of evidence for biologically based claims (Connell, 1987; Fausto-Sterling, 1985; Greene, 2004; Montagu, 1980; Sayers, 1982). The variability of human behaviour within the sexes is simply too great, and the mechanisms by which sex chromosomes influence behaviour is too obscurely defined to explain complex human behaviour in biologically adaptationist terms.
- The inappropriate application of a biological evolution model to explain cultural change, which develops through diffusion, accommodation, and learning from others rather than through differentiation and selection.
- The a priori and consequently unscientific logic of biologically reductionist views. Such claims are not subjected to critical empirical testing or logical scrutiny.

Sex-Difference Research

The interest in identifying biological differences between men and women has persisted. Particularly within psychology, sex-difference research developed into a speciality (Bem, 1985). It has been subjected to strong methodological and theoretical criticism (Ashmore, 1990; Crawford, 1989; Maccoby & Jacklin, 1974). Underpinning much of the *sex-difference research* is the assumption that observed differences between the sexes are due to their innate dispositions. The social scientists’ job is to identify these differences and their causes. For example, girls and women are commonly believed to be more empathic, while boys and men are said to be more rational. This may be used to explain the reasons why fewer girls may take up IT; they are put off by the cold logic of technology (see Barnett & Rivers, 2004).

This approach can be criticised on a number of grounds. It has been very difficult to demonstrate empirically that differences between the sexes are significant (Ashmore, 1990; Crawford, 1989), and most differences cited are slight or trivial (e.g., ability to throw). Moreover, gender is too complex a phenomenon (culturally and historically) to be explained simply as an attribute of individuals. It may be more like a force acting on the individual than something within the individual. It has also been pointed out that sex-difference research does not adequately deal with motivations for maintaining and producing the current relations between the two genders. For example, how do we explain the resistance and hostility often expressed against women who enter nontraditional occupations such as IT (Foster, 1996)? As with biologically reductionist accounts, sex-difference research was accused of attempting to find differences in order to defend the social and political status quo (Ashmore).

Feminist Approaches to Gender

A body of scholarship emerged in the 1970s that took a critical approach to gender and sought both theoretical explanations for the social positions of men and women and a political strategy for addressing gender inequality. This field is described as feminist theory. Several strands of theory appear within the feminist tradition.

Some theorists saw gender differences as based entirely on the social shaping of individuals from infancy. People are taught to think and act in a particular way based on their physical sex characteristics. This sex role learning is seen to account for most of the observed behavioural differences between men and women. Gender socialisation (sometimes described as conditioning), in turn, limits the options of individuals. This approach highlights the importance of learning in the production of gendered behaviour and the arbitrary and changing nature of many gender traits, and it is related to different practices in educational institutions that subtly (or otherwise) encourage boys into appropriately masculine fields (e.g., mathematics) and girls into feminine fields (e.g., humanities and nurturing activities; Gilbert, Bravo, & Kearney, 2004).

Another strand of feminist theorists located the motivation for socially created gender differences in the political and economic sphere (see Barrett, 1980; Burton, 1985; Hartmann, 1981). By linking gender differences with the system of production, they argued that the underlying motivations for shaping the experiences of men and women differently included the ability to exploit women both as employees and as childbearers (Eisenstein, 1978).

In contrast to theories that minimised gender differences, some feminist writers emphasised the differences between men and women (see Connell, 1987, for a discussion). They argued that there are real differences that have been misinterpreted to the disadvantage of women. The origins of these differences were variously explained in terms of the parental division of labour (Chodorow, 1978), thinking and moral reasoning (Belenky, Clinchy, Goldberger, & Tarule, 1986; Gilligan, 1982), reproductive and sexual function (Firestone, 1972), and the distinctive social location of women (Collins, 1990). Others argued that women had a special (collective) understanding and sensibility arising out of their social location or standpoint (Harding, 2004; Hawkesworth, 1989).

Within information technology, this tradition can be seen in the work of Adam (1998), which seeks to transform information technology into more feminist understandings of technologies, sciences, and cultures rather than to seek to fit girls and women into the current masculine approaches. Women are seen to have a different perspective on the world that at once excludes them in the world, but on the other hand provides them with a special insight into that world and its alternatives.

Such views, sometimes described as radical feminism, are ultimately as *essentialist* as are those associated with sociobiology (Eisenstein, 1984). To be able to treat women as a universal and homogeneous category, it is necessary to identify just what it is that all women have in common. The problem is that within the category of woman is a diverse range of experiences that must be accounted for. It became recognised that neither women nor men are homogeneous social groups (Butler, 1990; see also West & Fenstermaker, 1995), and generalisations about sex groups are problematic.

Through three decades of research, theory building, and debate, it has been recognised that gender is an important social dimension and infinitely more complex than the simple dichotomies of man-woman and masculine-feminine encapsulate. Gender is not reducible to biological sex, and is not an essence or a set of core attributes of two mutually exclusive groups. This does not mean that gender is unimportant; there are real differences in outcomes in occupation, income, status, and life experiences for men and women. The theoretical challenge has been to develop a new approach to gender that recognises these differences but does not reduce them to biology or simple social conditioning.

Contemporary Approaches to Gender

West and Zimmerman (1987) and Butler (1990) independently developed similar approaches to this challenge. West and Zimmerman made an important distinction between sex, sex category, and gender.

- **Sex:** Sex is "a determination made through the application of socially agreed biological criteria for classifying persons as males or females" (West & Zimmerman, 1987, p. 127). What counts as male or female is not a given but the outcome of a social process. Certain attributes of the baby's anatomy are taken as indicators of the child's sex according to custom and science. We are placed at birth into one sex category or another. Subsequently, we relate to people not primarily on biological grounds, but on their "identificatory displays" (e.g., hair, clothing, bodily posture, and behaviour) that proclaim them as one sex or another. Sex category stands as a proxy for sex.
- **Gender:** Gender is the process by which one continuously demonstrates one's sex category (which may be either different from or the same as one's sex). It is the "activity of

> managing situated conduct in light of normative conceptions of attitudes and activities appropriate for one's sex category" (West & Zimmerman, 1987, p. 127). Gender is not something one is—some inner core or essence—but something one does in order to demonstrate membership in a sex category.

Butler (1990, 2004) similarly argues that gender is a style or act that has "no ontological status outside its performance" (p. 136). She posits gender as a set of performances, gestures, and enactments that produce the appearance of a gender essence, an essential "gender core." Gender is not a "stable identity," but is an "identity tenuously constituted in time" and "instituted in a stylized repetition of acts" (p. 140). Gender does not exist outside its enactment, and being male, for example, does not refer to some inner essence of maleness. Butler uses the term "performativity" to avoid implying that there is an underlying self or subject that directs the performances or enactments. Just as gender is produced through its enactment, so the subject, "the speaking 'I'," is formed as part of the production of gender. The fact that individuals are usually completely committed to their identification as males or females is a separate issue.

Gender as a concept has moved from being an assumed natural category to one in which gender is a process, an ongoing unfolding act that is continually shaped and refined. Gender behaviour is not informed by an inner core, biological or otherwise. It is informed by the mundane, everyday need to make sense to oneself and to others (West & Zimmerman, 1987). The "doing of gender" (West & Zimmerman) is not a trivial undertaking or easily displaced, but instead forms a framework in which the individual can understand himself or herself and others.

These formulations are known as practice or process theories of gender. On the one hand, they argue that the different attributes and behaviours of men and women are arbitrary and historical products. But they recognise that gender forms part of our very identity and understandings of the world, and they are no less real, nor less tenaciously held, as a result. Gender practices are socially constructed but nevertheless extremely difficult to change.

FUTURE TRENDS

The implication of this changing concept of gender for information systems is that we must recognise that the problem of gender imbalance in the discipline is both multifaceted and embedded within our identities, our social practices, and the social fabric. This, rather than biological factors, is why gender patterns in fields of study are seen as natural. The lack of change reflects not only an overdetermination of practices, but our constructions of our everyday practices. This suggests that any change is likely to be slow and difficult.

Those who want to explore gender phenomena in information systems will find value in postmodern feminist approaches that challenge both the naturalness of gender and the alternative: socially determinist explanations (e.g., Adam, 1998; Butler, 2004; Green & Adam, 2001). They will recognise that the technologies themselves are imbued with our gendered understandings. This will strengthen the objective of using research to help achieve greater involvement with information technology by girls and women.

CONCLUSION

In this article we have seen how the conceptualisation of sex and gender has developed since feminist scholarship raised both theoretical and social issues, and how different schools of thought have treated these concepts. The importance of gender has been acknowledged, and biological sex is less commonly invoked to explain behaviour. We are now less likely to see gender as an attribute and are inclined to recognise it as a process, both socially imagined and individually performed.

These new conceptualisations do not imply that gender as a social category or an individual identity is infinitely malleable or less real than biologically based sex. It cannot be readily engineered, discarded, or ignored (Shapiro, 1991). The challenge is to understand the substantial and ubiquitous nature of institutionalised gender patterns without suspending our critical ability to contest and alter them.

KEY TERMS

Biological Reductionism: The attempt to reduce all significant human behaviour to biological and adaptationist causes, and more specifically, to attribute any significant differences in male and female behaviours to the different biological roles of males and females.

Essentialism: The belief that a particular group or set of elements shares a common and invariable thing, substance, or thread. Gender essentialism argues that women share different attributes, behaviours, and emotions that are intrinsic to women and that are not shared by men.

Gender: Definitions may range from an attempt to distinguish the socially acquired rather than biologically determined differences of men and women, to contemporary views that argue that gender is the process by which one continuously demonstrates one's membership to a sex category.

Sex: A determination made through the application of socially agreed biological criteria for classifying persons as males or females (West & Zimmerman, 1987).

Sex Categorisation: The placement of an individual into one categorisation or another. Sex categorisation may be independent of biological criteria.

Sex-Difference Research: An approach, centred in the discipline of psychology, to identify the psychological differences of men and women, and girls and boys.

Socialisation: A general process by which members of a society learn or are otherwise enculturated into the ways of the society. Different theories identify different mechanisms for socialisation.

Articulating ICT Use Narratives in Everyday Life

INTRODUCTION

The most common definition of the information society lays emphasis upon spectacular technological innovation and the transformative effects of new information and communication technologies. The key idea is that breakthroughs in information processing, storage, and transmission have led to the application of information technology in virtually all, public and private, sectors of society (Webster, 1995). By the 1990s, to admire and indeed enthuse over new ICTs had become highly fashionable and popular. Such technological enthusiasm has become so pervasive that it has seeped not only into political and policy discourses, but also into the whole spectrum of the media and fora of public communication (Preston, 2001). In addition, discourses of the information society are often dominated and shaped by male commentators (e.g., Castells, 2000; Gates, 1995; Kelly, 1999; Negroponte, 1995). For example, when compiling a collection of the dominant players of international information-society discourse, Cawley and Trench (2004) were hard-pressed to find female commentators, succeeding only in finding 3 out of a total of 18 critics.[1]

We argue that the focus on the artefact, and thus technological celebration, takes precedence over the largely ignored field of technological uses and consumption issues. Hence, we present a study that analyses the individual user experiences to challenge the stereotypical user traditions represented by the information-society discourse. We wish to present a counternarrative that shifts the emphasis from technical expertise, and technological and transformative benefits of artefacts to more individual-user-focused narratives.

As a result, this brought about a dual-narrative process through which the respondents described their experiences. We found that when people described their uses, consumption patterns, and domestication[2] experiences of ICTs, they tended to do so by employing contrasting frames of reference. These frames of reference we have termed the objective lens (or narratives) and subjective lens (or narratives). Through what we term objective narratives, we found that some respondents would describe their use through official and technical frames of reference. For example, they employed primarily dominant information-society jargon to frame how they made sense of technologies and their use experiences. Through subjective narratives, we found that respondents would describe their use and experiences from primarily a personal perspective to explain how the technology fitted their lives, the role it played in their everyday routines and habits, and the associated meaning and significance of the artefact.

While these contrasting narratives are not mutually exclusive or contradictory, it became clear from the interviews that a pattern of use narratives was emerging. We found that such narratives slightly reinforced traditional gender roles in which men tend to talk about technologies in highly technical terms of reference, while women portray themselves as technologically helpless or ignorant (Gill & Grint, 1995; Gray, 1992; Lie, 1995). Although we did not look for or find stable gender categories, the emergent gender narratives seem to renew the existing gender roles that link masculinity and technology (Vehviläinen, 2002).

With the development of computer technologies, we have witnessed a shift from IT to ICTs. This has resulted in a redefinition of the computer as an artefact: from a mere computational device to the newly emergent multimedia-enhanced computers, or what Paul Mayer (1999, p. 1) calls a "metamedium." Today, the conceptualisation of the computer is more problematic. It may be thought of as the Web or Internet, computer games, CD-ROMs (compact disc read-only memory), reference works, e-mail, and a diverse range of applications for displaying and manipulating text, images, graphics, music, databases, and the like. Spilker and Sørenson (2000, p. 270) argue that computers are no longer "primarily about programming, systems, control and calculation," but instead "a gateway to communication and cultural activities." The shift in identity has opened up or unlocked the conceptualisation of the computer. Therefore, it is possible for wider audiences and previously excluded groups (such as the elderly and women) to translate the computer into something meaningful in their everyday lives. As a result, we were not solely focused on the computer as a separate technology, but instead on the wide range of information and communication technologies that are available in the domestic setting.

BACKGROUND

While the concepts of objectivity and subjectivity are not novel terms to describe contrasting positions, we have used the concepts to facilitate the understanding of how our respondents talk about their experiences and uses of ICTs. Orlikowski and Robey (1991) have employed this approach to address the relationship between information technology and the structuring of organisations. The authors argue that the essence of both social reality and ITs can be described by using objective and subjective perspectives. In Orlikowski and Robey's approach, the objectivist relationship to technology underlines the importance of the material characteristics of the artefact, while the subjectivist approach focuses on the importance of the subjective human experience in the interpretation, creation, and modification of the social world.

Although Giddens' (1976) theory of structuration bridged the gap between the objective and subjective social reality in academic circles, and in particular technology studies, the emphasis lies firmly in the objective approach (Orlikowski, 2000). We argue that one must consider both subjective and objective approaches to ICT discourse. The division is maintained in this article as it is constructive and valuable in the ways it enables us to discuss how and why the objective approach to articulating ICT use is publicised, overvalued, and hyperbolised. On the other hand, the subjective approach is often neglected and confined to private, domestic, and unofficial realms. The aim of this article is not to merely point to the existence of both discourses of ICT use, but instead to argue that it is important to locate the common ground between the discourses in order to provide a grounded and holistic picture of the ways people talk about their ICT use.

NARRATIVES OF ICT USE

The data for this article are drawn from a larger study of Finnish families looking at ICTs in everyday life and the use of electronic services.[3] The objective-subjective theme discussed here emerged while analysing the ways family members talked about their ICT use. For the purpose of this article, we draw on selective excerpts from the interviews to illustrate the contrasting narratives.

Pure Objective Lens

The dominant narrative of information-society discourse presents ICT use in a normative way, for example, by urging universal access and consumption, which is mirrored through official discourse in the ways everyday users express their personal experiences. This way of describing ICT use was also reproduced by several respondents, as can be observed in the following quote.

Ville: We had our first computer ... [it] was 2-8-6 ... quite interesting. We have it actually still somewhere; I don't know where.
Interviewer: Was it about when ... [W]ere you still in school?
Ville: Well, it was when [it] cost thirty grant[s] of old money.

Here, Ville was asked about his early memories of the family's first computer, and he replied listing only the technical particulars and the price of the machine. The quote gives an interesting insight into how male respondents often shied away from using personalised or subjective narratives to articulate their everyday use of or relationship with the artefact. Instead, they preferred to employ objective or dominant information-society narratives to describe their relationships with ICTs. We found male respondents would employ such narratives even when discussing Internet use.

Information-society discourse, as we stated earlier, adopts the classic determinist position whereby technical advances are celebrated using hyperbolic expressions (Preston, 2001). This technical enthusiasm is picked up by ordinary users (mostly male) who tend to reproduce these official narratives to describe their own use.

Pure Subjective Lens

We also identified another narrative used by the respondents to describe their use in a more personal or subjective fashion. To illustrate this alternative narrative, we present one example of a female respondent who expresses her use and consumption of the Internet by relating its use to her everyday routines and habits. Here we notice a shift in the respondents' narratives from objective discourses of use to narratives of personal and individual ways of describing how the artefact fits into everyday life.

[On the Internet] there is lot of instructions, people's gardens, advice. Then there is from these willow works. You find really those instructions, real illustrated, and they talk [on Web pages]. I just devour those. (Helena)

When talking about her use of the Internet, she gives very practical (or subjective) descriptions of her Internet habits, incorporating emotive and expressive language to articulate her use patterns: "and then I can manage without [the] machine [computer], but it is nice to visit [Web pages] if I just can."

She also makes it clear that using the Internet is not an overwhelming activity for her, but one she can do well without. This she explains partly due to the everyday situation in the family, as access to the computer is compromised due to other family members being active users.

Mixed Objective and Subjective Lens

Helena's husband Heikki gives us a very useful insight into the dilemma users face when trying to balance the objective and subjective relationships with the computer. He explains,

I don't really like [to] use it much then ... I don't know if it's character or what, but I feel bad if I'm not working; then when I'm by [the] computer ... I feel I'm wasting my time ... but I do sometimes [on] weekends. (Heikki)

In this quote, we get a sense of how users strive to reconcile the work-related or non-hobby-related uses of the computer and the Internet (objective) with the leisure or entertainment features and functions, and perhaps even communicative elements of ICTs (subjective). Objective discourses tend to focus on "worthy" or beneficial uses of ICTs while perhaps overlooking the everyday uses such as music downloading, game playing, surfing, and e-mailing. It is only through a subjective discourse analysis that we get a sense of the reality of everyday uses of ICTs and accordingly develop an understanding of the meanings and significance users assign to them.

TRADITIONALLY GENDERED OR GENDERED TRADITIONS?

This section will explore whether gender differences between masculine and feminine users are reinforced, reproduced, or challenged. Ostensibly, there existed some gender differences in describing one's own ICT use. It became apparent during the respondents' narrations that both men and women appeared to adhere to traditional gender stereotypes, in which men are presumed to be technologically oriented and women technologically helpless, or at least not interested in technology (Gill & Grint, 1995). In doing so, they do not just express their own interpretations, but they appear to also confirm and renew the connection between technology and masculinity.

However, on deeper analysis, we found some interesting similarities between the male and female approaches to describing ICT use. We suggest that the presence of such similarities can be argued perhaps as a weak indication that signals the diminishing traditional bond between technology and masculinity (Lie, 1995).

In our interview material, the men, Pekka, Heikki, and Ville, used all three narratives (objective, subjective, and mixed narratives). In spite of this, there also emerged some crucial differences between the men as Ville employed almost exclusively the objective narrative, even as he presented his individual ICT experiences. The other men, Heikki and Pekka, employed mixed narratives when articulating their ICT use. This reinforces the position held by Lie (1995), who argues that "the connection between technology and masculinity does not imply that all men are equally attached to technology, or that one can prove empirically that majority of them are" (p. 382).

Alternatively, the interviewed women, Paula, Helena, and Leena, employed subjective and mixed narratives. Significantly, they did not employ objective narratives at all. It became apparent that Leena was more aware of the objective discourse, but chose instead to articulate her ICT use in more subjective tones. Paula was quite enthusiastic about computer use and the potential benefits of the information society, using objective narratives to express her opinions. But when she described her individual role as an ICT user, she presented herself as "not the good and legitimate user," which can be seen as reverting back to subjective narratives. In essence, the female respondents knew of the dominant narrative of information-society discourse, but they used it as a mirror to present their own subjective experiences.

FUTURE TRENDS AND CONCLUSION

Although the objective lens continues to be used as the dominant narrative, we believe the subjective lens will become increasingly pervasive with more user- and consumer-focused research (such as Hartmann, 2003; Miller & Slater, 2000; Ward, 2003). This type of research mirrors the changing faces of ICTs from highly technical artefacts (bound up with programming and networking identities) to technologies with everyday uses for domestic users (with communicative and interactive functions). This shift brings about opportunities for ordinary users to articulate their own subjective relationships with ICTs while lessening the need for dedicated technical expertise and skills to operate information technologies. From a cultural- and media-studies perspective, Silverstone, Hirsch, and Morley (1994) view the "double articulation" of ICTs—both technological texts and media texts—as having an influence on relationships with ICTs, and in the case of this article, on the discourses people use to describe those relationships. As a result, ICTs are not solely studied from a technological perspective, as by computer scientists, but also from social and human-centred perspectives (e.g., Castells, 2000; Hine, 2000; Lie & Sørensen, 1996).

Furthermore, the scientific paradigm is recognising this shift as studies become less positivist in nature and instead focus more on areas such as interpretive studies (see Walsham, 1995, 2005). In the information-systems field, interpretive studies provide space to consider alternative explanations of ICT use and practice, in particular in new gender studies where the focus is not typified by the differences between the genders but instead on subjective differences, for example, between women's use of technology. Therefore, we suggest that the subjective analysis of technology use and its discourse should be considered a valuable insight into how users construct individual interpretations of ICTs. In cultural and media studies, the concept of domestication is employed to achieve insights into the experiences of individuals as they tame wild technologies and make them fit into their everyday surroundings, routines, and patterns. Domestication, as an analytical tool, gives scope to researchers to consider the technological and social characteristics of technology and the social factors that influence its use and identity. This approach to technology and everyday life marks a move away from the understanding that technologies appear in society ready to use, to an understanding of technologies as unfinished artefacts. It provides a very useful way of exploring the social complexity of how people experience ICTs beyond any simple idea of the benefits and uses of technology.

In conclusion, as ICTs become more a part of everyday life, we believe the stereotypical connection between technology and masculinity will focus less on male users and female nonusers, but will focus more accurately on the kinds of uses there are and how those uses are articulated. We posit the technology-orientated male will be replaced, for example, by the sophisticated image and narrative of the open-source programmer, with all the superfluities of high technical expertise. Meanwhile, the technologically helpless female is interchangeable with representations of unsophisticated use or everyday uses of information and communication technologies.

INTERVIEWS

The interviews conducted in South Ostrobothnia, Finland. Names of the interviewees have been changed:

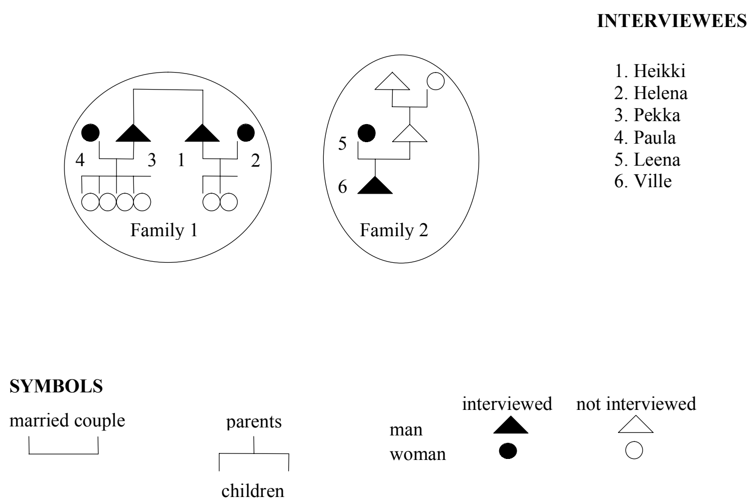
Heikki, interviewed June 2, 2003, by E.-R. Koivunen
Helena, interviewed June 2, 2003, by M.-K. Paakki
Leena, interviewed June 24, 2003, by M.-K. Paakki
Paula, interviewed July 16, 2003, by M.-K. Paakki
Pekka, interviewed July 16, 2003, by E.-R. Koivunen
Ville, interviewed June 25, 2003, by E.-R. Koivunen

APPENDIX

Two of the project members, researchers Koivunen and Paakki, collected the empirical material and interviewed the respondents in the summer of 2003. The interviews were conducted in a South Ostrobothian village in Finland. In the village, there are 400 inhabitants, a school, a shop, a bank, and a church. The interviewees are members of two extended families (see Figure 1).

Family 1 is comprised of the households of two brothers and their families living next to each other. The brothers, for whom we use the pseudonyms

Figure 1. The interviewees and their family relations



Heikki and Pekka, are both married and have young children. Heikki and Helena have two daughters, while Pekka and Paula have four daughters. In these families, all members use the computer and the Internet. We interviewed the brothers and their wives. These interviews took place at their homes.

Family 2 includes a grandmother, grandfather, father, mother Leena, and a 20-year-old son, Ville. They all live on the family farm. From this family, we interviewed only the mother and the son, who are both known in the village as active and innovative users of ICTs. The other members of the family do not use the computer or Internet. Leena was interviewed at her workplace, which she called her second home, while Ville was interviewed at home.

KEY TERMS

Domestication: Domestication refers to the process whereby technological artefacts are fitted into the routines and practices of the everyday lives of users. It is a process whereby technologies are consumed within specific and localised contexts and become inscribed with meanings, while reproducing values and transforming relations.

Dominant Narratives: Dominant narratives are part of our shared cultural knowledge about standards, which we refer to in explaining our acting, knowing, and thinking, and they are produced and reproduced in the discourses of everyday life.

Double Articulation: Double articulation refers to the concept that media lead double lives as both communication media and artefacts. Technologies are doubly articulated in the ways we need to address responses to particular texts or genres brought to us by the media and, on the other hand, the significance of media technologies themselves.

ICTs: Information and communication technologies such as televisions, telephones, the Internet, computers, and so forth.

Information Society: This concept is characterised by a new kind of information-led, service-oriented society that will replace the industrial-based model that had been dominant in the West in the 19th and 20th centuries. Information, and those who know how to create, assemble, and disperse it, is deemed more valued than labour.

Objective: The objective is nonsituated, impersonal, and not dependent on or influenced by personal opinions or prejudices.

Subjective: The subjective is based on thoughts or feelings derived from individual experiences and personal interpretations.

ENDNOTES

1. Those female commentators are Sherry Turkle, Esther Dyson, and Robin Mansell.
2. Domestication here refers to the process of rendering new technologies as tame as they enter the domestic setting.
3. See Appendix for an extended account of the empirical data sample.

Attitudes Towards ICT in Australian High Schools

Kaylene Clayton
Griffith University, Australia

INTRODUCTION

Information and communication technology (ICT) is integrated into almost every daily activity. Yet, few females today are choosing ICT based careers; a large percentage prefer to work in "pink collar" jobs such as childcare, education, and nursing. A recent report (Queensland Government, 2004) states that the average weekly earnings of full-time female workers in ICT, personal services, education, and health careers are $883.30, $513.10, $802, and $854.20 respectively. Furthermore, even though females consistently earn less than males, female ICT workers record the highest average earnings for all female occupations. Not only are females rejecting the financial rewards associated with ICT careers in favor of jobs that are seen to have a high human concern, they are also denying their voice in the creation and development of future technologies and applications. However, why are they shunning ICT study and careers? How does their educational environment and their perceptions of ICT impact ICT study and career choices? This article explores these questions through the 2003 case study of Year 9 and 12 students, teachers and guidance officers at two co-educational schools in Queensland, Australia. Data was collected from 490 participants through questionnaires and six students and four teachers took part in interviews. Two theoretical frameworks, organizational culture and information quality, were used as a lens to view the situation.

BACKGROUND

The longstanding debate over whether females are not engaging in ICT careers because they are biologically not suited to technical work (essentialism), or that they have been nurtured to believe that they are not suited to technical work (social construction), continues to be contested. However, new theories, including Trauth's (2002) theory of individual differences, are emerging to address the flaws and gaps within these theories. The underrepresentation of females in ICT is also not a global phenomenon; there are cultural pockets in the world, including Mauritius, where females represent a relatively equal proportion of the ICT vocational and educational cohort (Adams, Bauer, & Baichoo, 2003). However, it is a well-documented problem in Western cultures, including Australia.

Research shows that females are methodically guided away from technical fields during school through classroom culture, traditional gender roles and other societal pressures (Gorski, 2002). Some of the enduring ICT stereotypes are that ICT professionals are Caucasian males with antisocial tendencies (Countryman, Feldman, Kekelis, & Spertus, 2002; Gürer & Camp, 2002) and that ICT is boring and "geeky" and involves working long hours in social isolation, (Joshi & Kuhn, 2001; Myers & Beise, 2001; Newmarch, Taylor-Steele, & Cumpston, 2000). Popular media has enabled mass reinforcement of these established and often undesirable ICT stereotypes and there is a distinct lack of both fictional and real ICT role models who are given media coverage (Multimedia Victoria, 2001). Job security is also important to senior school students (Multimedia Victoria, 2004). Today's youth witnessed the "dot-com" boom and skills shortage followed by mass redundancies and unemployment in ICT during the bust. This episode was highly publicized by the mass media, but the recovering ICT job market has not been given the same level of publicity. According to the Oliver Group director, the technology sector grew almost 56% in the twelve months from March 2004 (Foreshew, 2005). Anecdotally, many students and their parents believe that the ICT job market is still depressed and express surprise when informed about the recovering market.

Many students lack information about ICT work and exhibit little understanding of the nature of ICT jobs (von Hellens, Nielsen, & Beekhuyzen, 2004). They do not know about established ICT occupational roles, such as being a computer scientist, let alone the new opportunities that are being created and thus do not know how their talents and skills apply in that field (Jepson & Peri, 2002). However, describing the ICT area, including job roles and areas is a non trivial exercise, even for experts in the area (Spencer, 2003). Australian students are also receiving limited information about ICT subjects and choices available to them (Van Der Vyver, Crabb, & Lane, 2004). Students have been exposed to ICT integrated into the general school curriculum, but few have a clear idea of what is involved in ICT subjects (Sheard, Lowe, & Markham, 2001). Compounding the issue within vocational education, career advisors often admit to struggling to understand ICT jargon and job descriptions (Standley & Stroombergen, 2001) leading to the lack of confidence in giving ICT career advice (Multimedia Victoria, 2001).

The way that the ICT curriculum is introduced and the learning environment impacts on the ICT attitudes of students is of high concern. It is imperative that the curriculum provides future ICT students with coursework which interests both sexes whilst providing them with the appropriate skills to enter ICT career paths (Gürer & Camp, 2002). Yet, many students report negative opinions of ICT specific subjects and general dissatisfaction with the ICT curriculum (Carey, 2001; Multimedia Victoria, 2001). These opinions could be partially because the predominant content of ICT subjects in schools involve word processing and spreadsheets (Downes, 2004) providing the students with a skewed perception of the true nature of ICT careers (Multimedia Victoria, 2001). ICT educators must not only focus on good teaching, but they must also evaluate whether the subject is seen to be challenging, useful and interesting (Mitchell, Sheard, & Markham, 2000). The ICT learning environment has a number of unique features including a predominantly male teaching cohort, who usually have a science or mathematical background, and a curriculum and associated assessment and exercises driven largely by masculine interests (Logan, 2004). Also, according to Carey (2001), teachers presently receive little or no training in the ways that technology can be used to create an equitable, innovative and engaging learning environment.

IMPACTS ON ICT PERCEPTIONS

Organizational Culture

Culture is the product of a social environment and evolves through the course of social interaction (Hofstede, 1997, p. 5; Morgan, 1998, p. 130). Cultural influences can shape perceptions about ICT, how ICT is used, and in turn the potential entrants to vocational and occupational areas in ICT and related fields (Harris & Wilkinson, 2004). Allaire and Firsirotu (1984) created a conceptual framework to assist in the analysis of organizational culture that consists of three inter-related components: a cultural system; a socio-structural system; and the individual actors.

The cultural system is a system of shared and meaningful symbols, which is shaped by its surrounding society and organizational history (Allaire & Firsirotu, 1984). There were a number of symbolic artifacts specific to ICTs that were observed amongst the responses from teachers and students, including terminology such as "hacker," "geek", "nerd," and "square" when talking about ICT workers. The students linked ICT success with these symbolic artifacts when 24% of Year 9 students and 41% of Year 12 students stated that it was necessary to be nerdy/geeky to be successful in ICT careers. However, these symbolic artifacts are commonly used in a negative social context and tend to deter students from engaging in activities that would have them labeled as such. Other common beliefs repeated in teacher comments were that computers are seen as toys for boys and tools for girls. Female teachers also identified with these beliefs and one commented: "[computers are] strictly a tool to be used, not to be aspired to." If computers are continually portrayed as something serious, rather than enjoyable, this may explain the reluctance of students to become involved in ICT. Students and teachers often regarded ICT subjects as being difficult with some students rejecting ICT subjects out of concern for their academic results and university entrance scores.

The socio-structural system consists of management strategies and policies and formal structures (Allaire & Firsirotu, 1984). All schools must comply to a certain level, with standardizing educational policies of the government, but the way that the curriculum is developed and delivered can affect the way in which the subject is viewed. The cost of providing and maintaining ICT resources and infrastructure is an issue and the lack of financial and physical resources affects the delivery of the ICT curriculum and how it is (negatively) perceived by the students and teachers. One teacher also felt that if a student was ICT inclined then that they would find alternative ICT resources outside of the school. Yet, in low socio-economic areas, many families still do not have access to computers at home and rely on schools and libraries to provide those resources. Many teachers and students complained about the quality and quantity of resources available, with only 25% of teachers at one school saying departmental budgets allowed the purchasing of adequate resources to deliver the curriculum. Teachers also commented that students sometimes cause further damage to broken computers out of frustration or boredom.

Personnel, classroom availability, and timetabling were other ICT resource issues that caused tension. Students were foregoing ICT subjects because of timetabling conflicts saying that "[ICT subjects] have to be sacrificed to fit other first priority subjects in." Teachers also identified that ICT subjects were the most time consuming to prepare for. "It needs more preparation time because things change so rapidly … I could go back to teaching chemistry tomorrow and yes, the syllabus has changed fractionally, but the basic chemistry hasn't changed in 50 years and the level we teach at high school won't change." Another teacher also conceded that it was difficult to foster and maintain student interest in relation to ICT saying, "it's hard to interest them because they have computers and the Internet at home."

Individual actors bring their own experience, personality and legacy to an organization and depending on their status can contribute and mold reality (Allaire & Firsirotu, 1984). Students have their own motives in relation to whether or not they enroll in ICT study and factors influencing these motives include enjoyment of the area, career aspirations, and opinions of friends, family, and role models. When students were asked what influenced their career decisions, the top responses included family and friends, but also high on the list was TV shows. Most students found that ICT subjects were boring, but others planned to combine ICT with other interests: " … this is a way of doing music and technology at the same time." When students were asked about the most appealing factors for an ideal career, the top response was interesting work followed by high salary and working with/meeting other people. These factors recognize social, remuneration and lifestyle aspects of future careers and are generally opposite to what ICT is perceived to involve.

Information Quality

Individuals often have differing opinions, wants and needs, and as such, each individual's definition of quality may vary significantly (Garvin, 1984). Schools are required to teach a certain amount of core information, but the way that this information is taught will differ between different schools and teachers. A teacher reiterated this when asked whether the ICT curriculum prepares students for ICT careers: "Depends which school." Some schools do not offer compulsory foundation ICT subjects in Year 8, whilst others do. Consequently, students who need to make informed decisions about subject selections in Year 9 and 11 may be disadvantaged at schools who do not offer these foundation subjects. Students also recognized the impact of foundation subjects on subject decisions in senior high school. Comments included: "in Year 9 we do Web pages and in Year 10 we do programming and that whole last semester of programming is like an introduction to IPT [a senior ICT subject]" and "you do math from Grade 1, but you don't do computer programming from Grade 1; you don't know what you are walking into."

Teachers are expected by society to have a wide range of knowledge, skills, and ability in their area of teaching. However, the rapid changes in ICT create problems for ICT teachers. Teachers also recognized the need for qualified ICT teaching staff. One teacher also told of his entry into the ICT classroom: "I arrived in my second school as a third year teacher and the computer teacher had gone away on leave for 6 or 12 months and they said, 'you're young, here is the computer room, you are teaching the class tomorrow' … and that was my first introduction to computers." ICT teachers also recognized that the ICT curriculum was dated and lacked relevancy, possibly because of the limitations of subject texts. One teacher also commented that the senior ICT subject "is too narrow a context for the modern use of computers … " Students also expressed general dissatisfaction with the ICT curriculum saying that it was boring and that theory outweighed the practical work. Another problem with ICT subjects in high school is that they are not a prerequisite for tertiary ICT study. Teachers and guidance officers also face difficulties with is the changing job roles in ICTs. As advisors, if they are not well informed, it is difficult to understand how they could give accurate, current, and reliable ICT career information to the students. Who is educating the students about their ICT career options?

FUTURE TRENDS

Investigation into the declining number of females entering ICT study and career paths has been underway for over two decades. Today, we are no closer to finding a solution to this problem, as we were twenty years ago. In fact, the decline of females entering ICT tertiary education is becoming worse over time. Previous studies, including this one, have investigated various points of view and factors that may influence female ICT career decisions. Some of the factors identified include national and organizational culture, lack of or poor quality ICT career information, societal influences, discriminatory work environments, practices and policies along with the need for appropriate ICT role models. Another complicating factor is that the world and the ICT industry are not static. If you add to this volatile mixture, the changing and individual needs of the girls, the puzzle becomes increasingly complex. While these studies have contributed by identifying these issues and making recommendations for change, some which have been instituted, this complex social problem has not been solved.

These factors, however, cannot be looked at in isolation. All things being equal, it would be expected that girls who are given the same information and experience the same social and cultural values and information, would have similar career goals and paths. However, this is not the case. Could it be that we are concentrating on the negativity of this problem rather than celebrating the positive outcomes that already have been achieved? Perhaps researchers in this area need to reverse the question and ask the individual girls already enrolled in ICT subjects and careers, what drew them to the area and what drives them to achieve and succeed. Additionally, individual personalities and academic abilities cannot be disregarded when investigating career choices and the declining female ICT cohort. Individuals have distinct personal likes and dislikes; it has to be remembered that some females, and males for that matter, will never find ICT interesting, and it is an exercise in futility, to change them.

CONCLUSION

Although the ICT industry is known for its cyclic nature, people working in it are generally well remunerated and seen as being in a position of power and status because of the enormous role that ICT plays in business and everyday life. These benefits of working in the ICT industry, along with having a voice in the design and use of ICT, can impact positively on the quality of life and the lifestyles that women and their families experience. This study found that Australian girls are continuing to reject ICT careers partially due to negative perceptions and stereotypes. There also is a lack of adequate resources and trained ICT teachers passionate about teaching ICT, and students are frequently rejecting ICT subjects because they are seen as dull, boring and not meeting their needs. They are also rejecting the opportunity to work in ICT careers because of school experiences, the lack of accurate, meaningful, and timely ICT career information and positive role models. Finally, the influence of popular media on career decisions is an important area that should be exploited. Perhaps, in the future we may see shows about sophisticated and powerful women in ICT careers leading to increased ICT interest. We can only try.

KEY TERMS

Essentialism: The belief that traits are biologically determined and do not vary between individuals or genders.

Guidance Officer: A person whose role in a high school is to assist students with career information and guidance, assess students with special needs and provide students with support and personal counseling.

ICT: Information and communication technology is a broad grouping of technologies which include IT and telecommunications. Areas incorporated include computer science, software development, the study of organizations and society, mobile telephony and networks.

ICT Role Model: A person who has an interest, background, or career in ICTs whose behavior, attitude, or achievements make them worthy to be admired or imitated.

Pink Collar Jobs: Jobs that generally have a female dominated workforce such as: nursing, cleaning, childcare, primary school teaching.

Social Construction: Hypothesizes about the way that we analyze and categorize our experiences that influence and form our understanding of reality in our own social context.

Symbolic Artifacts: A way of making things known by signs and symbols which can include language.

Australian IT Enrollment Trends and Model of Contributing Factors

Catherine Lang
Swinburne University of Technology, Australia

Judy McKay
Swinburne University of Technology, Australia

INTRODUCTION

Australia, like other western nations, is experiencing a *downturn* in overall *enrollments in higher education information technology (IT) degree courses* as well as in the proportion of females selecting these courses. The percentage of women enrolled at a university in Australia, as a proportion of all enrolments, has increased steadily over the last decade from 52% of the total student body in 1993, to 54% in 2003 (DEST, 2004). This increasing number of females on campus is not reflected in *IT degree course enrollments*, where the number of female commencing students is steadily declining.

BACKGROUND

In Australian universities, IT courses cover a range of specialties: information systems, computing, computer science, software engineering, computer graphics, and database management are some example titles. The many names associated with the discipline, its relatively new nature, and the continuing growth in its application into new fields may account for this range of university courses offered in the discipline. The broad classification provided by the associated government department that gathers statistics divides the discipline into thirteen areas, which have been grouped in to four main categories for the purpose of this article: computer science, information systems, information technology, and information technology not elsewhere classified[1]. Figure 1 clearly shows the declining popularity of all IT courses with young women.

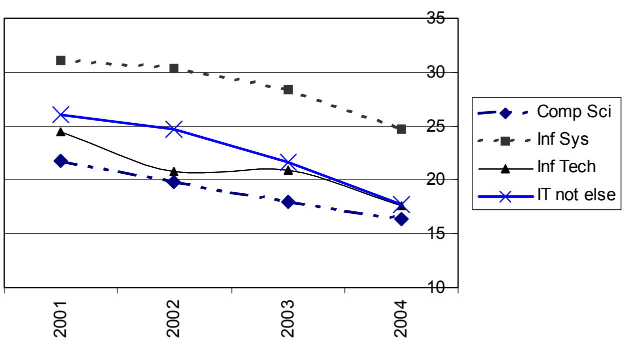
The downturn in popularity of IT degree courses is also evident in statistics related to student selection of university courses. Since 2001, there has been a decline of 46% in the number of students choosing IT as their first preference university course (VTAC, 2004). Divided by gender, there is an overall decline of IT course popularity of 65% in females and 40% in males (VTAC, 2004). This trend of declining popularity of IT degree courses is against the trend of young women embracing university education in general.

This apparent under representation of women in IT raises two questions. Why is the under representation an issue and why is there an under representation? An examination of the literature in this field and further discussion of these two questions is covered in the next section of this article.

WHY FEMALE UNDER REPRESENTATION IS AN ISSUE

A primary concern of IT academics and IT professionals as a result of the under representation and apparent declining interest in IT courses amongst

Figure 1. Female commencing students as % of total commencing students (within IT streams)



women is that the pool of talent being attracted to this discipline is not diverse enough and there is a "latent IQ" being overlooked (Richardson, 2003). The discipline is poorer because the under-utilisation of women results in a lack of the female perspective being reflected in IT projects in general (Richardson, 2003). Arguably women are excluding themselves, or being subtly excluded by social norms, from the opportunity to influence and shape future applications of IT in business, health, industry and education through not being involved in its design and application to an equivalent extent as men. The international women and computing literature expressing this concern can be traced back over twenty years, and provides information of government, education and industry funded programs to attract females to the discipline since the 1980s (Craig, Fisher, Scollary, & Singh, 1998; Wardle & Burton, 2002).

WHY THERE IS FEMALE UNDER REPRESENTATION

Efforts and intervention programs to attract women to IT appear to have had limited success and often negligible impact beyond the local area. Some programs implemented at secondary and tertiary levels in Australia and overseas have produced increases in enrolment numbers (Jewell & Maltby, 2002; Margolis & Fisher, 2002), but have not led to increases in the enrolment statistics in Australia in general. One particular study at a Victorian university found that a government funded Australia wide program initiated in 1990 to attract and retain women in IT fell well short of its aim of 40% female enrolments in higher education IT degree programs by 1995 (Byrne & Staehr, 2003). At the Australian Women in Computing conference in 1997, a collection of data from participating institutions showed that only two universities had met the government target of 40% female participation in only two of their degree programs (Byrne & Staehr, 2003).

The explanations given for this under representation will be discussed in the following sections. They have been logically grouped to provide a hierarchal overview of the extent of their influence. Overriding all is culture, which influences family, then education experiences, and last of all, the individual.

Culture

An overview of the cross cultural aspects of gender and IT is provided by Galpin who uses the "internal self-selection" model to explain why the lack of females in science in the U.S. cannot be applied to countries like India for example, where the family and not the individual is the decision maker (Galpin, 2002). While there is no evident pattern across countries, the expected role for females in the society, who the main decision makers in the family are, religious beliefs and education opportunities of females vary between cultures and all influence the decision to pursue a science or IT career (Galpin, 2002). An earlier study found that Asian women are less discriminated against and encouraged more by parents to follow career paths in IT (Clark & Teague, 1994). Preliminary results of a study across three countries (Australia, Hong Kong, and England) found a common perception of the IT discipline (male, isolated) held by both genders. This perception, rather than perceived academic difficulty, was the main reason given by participants for not choosing an IT career path (Craig, Paradis, & Turner, 2002).

Nielson, von Hellens, Greenhill, and Pringle developed a useful diagram that summarised factors affecting student perception of IT careers (1998). They included the key factors of gender, life history and cultural values that were influenced strongly by cultures of collectivism and cooperation (an aspect of Eastern cultures) or individualism and competition (an aspect of Western cultures). They concluded that national culture appeared to strongly influence perceptions of IT, more strongly than gender factors (Nielson et al., 1998). The strength of influence however cannot be measured and with the evidence in enrolments of fewer western females studying IT than females from Eastern cultures, the influence of culture appears quite strong.

Family

Family expectations are intertwined with culture and are a contributing influence to account for why women choose to study IT. The education level of parents influences whether girls decide on engineering, science or computing career path. This seems to be more applicable to females than males and the education level of the mother tends to be more influential in this decision that that of the father (Gayle, Berridge, & Davis, 2000). If the parents were also engaged in science and engineering the probability of child majoring in this area is increased (Leslie, McClure, & Oaxaca, 1998).

In families where there are high expectations placed on females to get an education and pursue a career, there is also typically existence of family friendly workplace policies, including a high level of provision of affordable childcare places and flexible working hours. Israel and some Mediterranean countries have family friendly societies (Galpin, 2002) where crèches and flexible working hours are provided to allow females to be equal contributors to the workforce. Before unification East Germany had over 90% of females in the workforce and a healthy 58% in IT (Oechtring & Behnke, 1995) and all workplaces provided crèches. Since unification the number of females in the workforce is less and the number of females in IT had declined to 9.5% (Oechtring & Behnke, 1995). While this decline cannot solely be attributed to childcare provision, the reduced support for females in the workplace is a contributing factor.

Arguably the economic situation of a family influences whether girls choose to study an IT degree or not. It can be surmised that the economic stability of the family directly influences whether a higher education degree for a daughter is feasible or not.

Education

The educational climate of the secondary school can strongly influence the expectation and feelings of self-efficacy students experience towards maths and technical subjects like IT (Bandura, 1997). According to Bandura (1997), as children master cognitive skills at school, they develop a growing sense of their intellectual efficacy. Cooperative structures in which students encourage and teach one another generally promote higher performance attainments than do competitive or individualistic ones (Bandura, 1997). Perceptions of self-efficacy have a direct effect on student choices in educational fields. According to Reeve (1996), students seek out situations that they judge themselves as capable of handling.

Experiences and opportunities in education also influence females' feelings of confidence when dealing with computers. Huff writes about the effect of "situational stress" on females and males (Huff, 2002). This is the effect of using a computer in a public setting, which negatively impacts on females to a greater degree than males (Huff, 2002). Unfortunately, computing and IT classes are often "bastions of poor pedagogy" (Margolis & Fisher, 2002). Many girls have commented on the intimidation they feel by being a minority in IT classes (Lang, 1999; Margolis & Fisher, 2002; Spertus, 1991) and the negative effect this has had on participation in classes. An encouraging and cooperative environment in secondary school, be it girls only classes or otherwise, is more likely to build an interest in IT than an individual and competitive environment.

The Individual

A common thread in successful IT programs initiated to attract women to the discipline is that personalised contact and on-going support is required (Clayton & Lynch, 2002; Jewell & Maltby, 2001; Margolis & Fisher, 2002). The basic premise that females need to be encouraged to persist in a male dominated field is reiterated by Townsend who purports that if the average female is to be given the same chance as the average male, there is still a need to counteract the unequal technical socialization that males get, in particular from the computer games market (Townsend, 2002).

Trauth's (2002) theory of individual differences employed empirical data to theorize the relationship between the social shaping of IT and gender identity. She explored "the way in which social shaping of gender and the IT profession operates at an individual level" (Trauth, 2002, p. 103). This theory has the underlying assumption that "inherent IT capability and interest spans the gender continuum" (Trauth, 2002, p. 104). Trauth emphasised the lack of cross-cultural identification with what is male and what is female in the research to date. "There are as many different 'women's experiences' as there are types of women" (Trauth, 2002, p. 102). Her study explored how the IT profession operates at an individual level. The individual differences theory is an extension of the argument that individual differences are a product of gender and socialisation within and between cultures. This theory is added to and extended in the model of contributing factors presented in the next section.

Figure 2. Model of contributing factors

The Individual	*Self-efficacy; ability to withstand implications that individual may not meet society's expectation of a female; ability to work in an occupation where they are a minority.*
Education	*Pre-school, primary, secondary, and tertiary educational experiences and opportunities.*
Family	*Influenced by culture; parental expectations; education experiences. Economic situation of the family is directly relevant to opportunities presented.*
Culture	*The root of it all. Where does culture place females in society? What role is expected of them?*

MODEL OF CONTRIBUTING FACTORS

The preceding model represents the layering of factors that contribute to the decision to study an IT degree course. It draws on the individual differences theory, and adds to it the influence of education, supported in the literature. Many aspects interact and build upon each other to influence the type of woman who will choose an IT career path. The model emphasises the base of culture and the overlays of family expectations, educational experiences and individual characteristics that will influence whether a woman chooses an IT career path or not.

To test the model of contributing factors a pilot electronic survey was carried out on female students enrolled in an IT degree at an Australian university. The aim was to determine if these students had commonalities in culture, family expectations, and educational background and whether or not these factors influenced their decision to study IT courses. Questions were designed to determine if there were patterns in prior education, (single sex school attendance, previous mathematics and science education) and family expectations (position in family, education level of parents, siblings already in university). Students were asked to indicate their familiarity with computers (at what age did they start using them, personal knowledge of a computing professional). The survey was created using specific software to allow for anonymity and made available via a secure Web-server. The URL for the survey was mailed to all currently enrolled students in four IT degrees. The survey was open for one month only. The response rate was 15%, but considering the time frame chosen for the administration of the survey (during the examination period) this rate is considered acceptable. This pilot study will provide a framework for a much larger survey, across the whole university, in the coming year. The results of the pilot survey with future relevance will be discussed in more detail in the next section.

FUTURE TRENDS

There are some emergent trends in relation to culture, family expectations, and educational background. The results of the questions to determine cultural background indicate that, in this sample, only half the students completed their final year of secondary school education in Australia which indicated that half the respondents were overseas students or very recent migrants to Australia. Given Australia's location in the world, it is not surprising to see that slightly more than half reported their cultural background as Asian (53%). Australia is considered a multi-cultural society, and this is reflected in the places of birth of these students. Only 40% were born in Australia. The emergent trend of half the students being Asian supports the individual difference theory of the culture of "collectivism" overriding individualism when choosing career paths (Neilson et al, 1998). IT is considered to operate at a particularly individual level (Trauth, 2000) and arguably, these results indicate that the collective nature of Asian family culture influences student career choice and overrides individual preferences and differences.

Family expectations are influenced by the culture in which the family live. The parents of more than two-thirds of these students were educated beyond secondary school (66% fathers and 77% mothers with 72% of the students having one or more parents who hold bachelor degrees). On closer inspection, the survey responses show that these students are the daughters of engineers, doctors, and education professionals (46% mothers, 57% fathers). They generally come from households where both parents work (85%). Two-thirds of the respondents are the first among their siblings to attend university (half of them are the oldest or only child) and 74% reported that their family had strong expectations of them attending university. The emergent trend is of high family expectations influencing career choices of these students, and supports the earlier findings that technically educated parents strongly influence the career paths of their daughters. It can also be surmised that the economic situation of the family has an influence, with the majority of families having both parents in the workforce.

The majority of students in this sample completed mathematics to the final year of their secondary school (92%), two thirds also completed science subjects, and IT subjects to final years of secondary school. They are computer literate, with 78% using computers before or during junior secondary school years. This could be a reflection on the self-efficacy of the students in relation to their education experiences, and that the math and technically capable students are choosing IT courses. To establish if this pattern is significant the survey will be widened in 2005 to determine the profile of students in other disciplines and to see if males fit the same profile as females in IT.

CONCLUSION

Educators are aware that there is no simple way to increase female participation in IT. The issue is multi-faceted, and despite over 25 years of intervention programs, the declining enrolments of women in IT are still a major issue. This article has provided a statistical overview of trends in higher education IT enrolments in Australia in the first few years of the 21st century. A model of influences has been tested against a small sample of current females enrolled in IT to determine if it is effective. This model adds the feature of educational experiences and gives this more prominence in influencing student career choice than earlier models. Some trends have emerged that need further investigation with a wider study.

KEY TERMS

Collectivism: Society culture that favours group decision making, group well-being and group progression over individuals.

Database Management: Creation and maintenance of an electronic database system.

Gender Continuum: Movable division between male and female genders.

Individualism: Society culture that promote ego and self beyond group culture.

Knowledge Poor: Lacking resources or facilities to access information.

Knowledge Rich: Having a plethora of resources available to access information.

Latent IQ: Potential knowledge not presently available.

Self-Efficacy: Belief that one is able to succeed in a given area.

Software Engineering: A systematic approach to the analysis, design, implementation, and maintenance of software.

Technical Socialization: Opportunity and resources available to enable familiarization with computer hardware and software.

ENDNOTE

[1] For the purpose of this paper DEST classifications for the broad field of study Information Technology have been used. They have been grouped by the authors as follows:

- Computer Science (020100 Computer Science; 020101 Formal Language Theory; 020103 Programming; 020105 Computational Theory; 020111 Data Structures; 020113 Networks and Communications; 020115 Computer Graphics; 020119 Artificial Intelligence; 020199 Computer Science not elsewhere classified)
- Information Systems (020300 Information Systems; 020301 Conceptual Modelling; 020303 Database Management; 020305 Systems Analysis and Design; 020307 Decision Support Systems; 020399 Information Systems not elsewhere classified)
- Information Technology (020000)
- Information Technology not elsewhere classified (029900 Other Information Technology; 029901 Security Science;029999 Information Technology not elsewhere classified)

The Beijing World Conference on Women, ICT Policy, and Gender

J. Ann Dumas
The Pennsylvania State University, USA

INTRODUCTION

The 1995 Fourth World Conference on Women, Beijing, China, addressed gender equality issues in many areas of global society, including information, communication, and knowledge exchange and the associated technologies. The Beijing Declaration called for action to promote gender equality in human rights, economic autonomy, domestic responsibility sharing, participation in public life and decision making, access to health services and education, and the eradication of poverty and all forms of violence against women. The Beijing Platform for Action contained strategic objectives and actions for governments and others to implement to increase gender equality in 12 critical areas, including Section J, Women and the Media. Article 234 of the Beijing Platform Section J acknowledged the important need for gender equality in information and communication technology:

advances in information technology have facilitated a global network of communications that transcends national boundaries and has an impact on public policy, private attitudes and behaviour, especially of children and young adults. Everywhere the potential exists for the media to make a far greater contribution to the advancement of women. (United Nations [UN], 1995, p. 133)

Section J defined two strategic objectives that address issues of access to and participation in ICT and media development.

J.1. Increase the participation and access of women to expression and decision making in and through the media and new technologies of communication.

J.2. Promote a balanced and nonstereotyped portrayal of women in the media. (United Nations, 1995, pp. 133-136)

Governments agreed to implement the Beijing Platform for Action and use gender-disaggregated data to report national progress on objectives during Beijing +5 United Nations General Assembly Special Session (UNGASS) in 2000 and Beijing +10 in 2005. This article reviews progress reported on ICT-related Section J strategic initiatives and trends for ICT and gender between 1995 and 2005.

BACKGROUND

The gender equality objectives in Section J have been rooted in international agreements among United Nations member nations since 1947. The Universal Declaration of Human Rights (UDHR) recognized that "the inherent dignity and the equal and inalienable rights of all the human family is the foundation of freedom, justice and peace in the world" (UN, 1948, p. 1). UDHR Article 19 affirms the right to communicate and "to seek, receive and impart information and ideas through any media and regardless of frontiers" (UN, 1948, p. 1). These human rights, equally inalienable for women and men, are affirmed in the international treaty Convention on the Elimination of all forms of Discrimination Against Women (CEDAW; UN Commission on the Status of Women, 1979). Prior to the Beijing conference, CEDAW was referenced in the preamble preceding the 1989 UNESCO Convention on Technical and Vocational Education, which "provides for the right to equal access to technical education and pays special attention to the needs of disadvantaged groups" (Hamelink, 2005, p. 128).

The United Nations Commission on the Status of Women organized four world conferences on women. The first was in Mexico in 1975 at the beginning of the United Nations Decade for Women and focused on equality, development, and peace with the subthemes of employment, health, and education. The second was in Copenhagen in 1980. The third, in Nairobi in 1985, produced the Nairobi Forward-Looking Strategies for the Advancement of Women (1985), which affirmed that the:

realization of equal rights for women at all levels and in all areas of life will contribute to the achievement of a just and lasting peace, to social progress and to respect for human rights and fundamental freedoms. (United Nations, 1985, p. 1)

Beijing 1995

The Fourth World Conference on Women in Beijing in 1995 built on the Nairobi strategies and created the Beijing Platform for Action (1995). Just prior to Beijing, the United Nations Commission on Science Technology and Development Gender Working Group (UNCSTD-GWG, 1995) compiled research on gender, science, and technology interactions, particularly on applications that serve basic needs in the developing world. Most of the case studies focused on technical change that had differentially impacted the lives of women and men, and found men benefiting more from technical change. Further analysis identified male dominance in the decision-making chain as a prime reason for gender inequalities (UNCSTD-GWG). The Beijing Platform for Action helped situate gender equality as central in the global development-policy agenda by creating a gender-sensitive policy framework for achieving development goals through action targeted to human needs. Governments agreed to the Beijing Platform for Action and committed some resources to implement the objectives of its 12 target areas and to monitor progress at 5-year intervals.

Beijing + 5

The Beijing Platform for Action Section J had affirmed the importance of gender inclusion in ICT policy development at local, national, regional, and international levels. By 2000, policies to direct the ICT tools, so celebrated for their potential to effect change in developing nations, were only sparsely implemented toward programs for women's development. UNIFEM executive director Noleen Heyzer (2000) voiced concern that "globalization has failed to generate formal employment for women, but instead shifted their work to the informal and casual sectors." She stressed the "pressing need to assist countries to develop new frameworks that transform globalization to become pro-poor and pro-women, a globalization that is more socially accountable" and to utilize "the possibilities for connecting women and markets worldwide through the democratization of information and communication technologies and policies." She addressed the issue of the representation of women and called for greater gender equity in "expression and decision-making in and through the media and new technologies of communication."

Toward this objective, UNIFEM partnered with Cisco Systems to host the gender and ICT session at the Beijing +5 UNGASS. The session reported on women's leadership in ICT capacity building and information sharing for development. Discussion focused on best-practice action programs for the Section J objectives expanded to include ICT. New media ICT access and participation had moved toward gender equality in ICT-rich nations. In ICT-poor nations, data were less available. Many cases were reported of women's empowerment through ICTs for education, political voice and decision making, employment, and capacity development, but key obstacles of poverty and illiteracy kept most women in developing countries from ICT access and participation (United Nations, 2000).

The United Nations (2000) report on trends and statistics published for Beijing +5 identified the "need for new data on new media" (p. 100) and found new media boundaries are blurred between "genres and delivery systems" and "producers and users" (p. 100). Support for gender equality in hiring and gender sensitivity in programming was recommended in order to address escalating trends of gender stereotyping, pornography, and other degrading images of women and girls in media. The 2000 report also found "almost no data" (p. 100) on gender portrayal in new media, including Internet broadcasts, games, and newsgroups. The report recommended the development of complex measurement instruments to do this because "representations of women cannot be separated from construction of identity, use of language and new styles of interaction" (p. 100).

Beijing +10

Ten years after Beijing, the United Nations Research Institute for Social Development (UNRISD, 2005) analysis and report on progress focused more on the broad global challenges to women's well-being than on the specific progress of Section J, Women and Media, including ICT. The Beijing +10 UNRISD report found overall "uneven progress in an unequal world" (p. 5) in part because the state, a central instrument for human rights protection, must be "democratized to deliver gender justice" (p. 258).

UNRISD (2005) reported that "market fundamentalism has reduced the legitimacy of the state as the maker of national rules about the obligations and rights of citizens" (p. 258). The report acknowledged some gender-equality gains in primary education, political representation, and reproductive rights, and the fact that there are more women in the labor market. However, ILO data in the report showed increased jobs for women in ICT and other sectors, but most were in informal and low-wage labor, so there was little overall economic progress for women since Beijing +5. ICT and economic development progressed concurrently in China and India, but without concurrent development of gender equality in education, health, and economic distribution (UNRISD).

The Beijing platform and subsequent progress assessments in 2000 and 2005 also considered research evidence that policies, guidelines, and perhaps technologies are more gendered than gender neutral, strengthening the argument for gender-inclusive data collection and analysis:

> *Project-level data has well established that telecommunication and ICT are not gender-neutral. They impact men and women differentially, and in almost all cases, women have lesser access to and use of the media and lesser representation in the power and decision-making positions related to telecommunications and ICT ... special attention is needed. Without it, women will have fewer opportunities to benefit from the myriad possibilities of the information age.* (Hafkin, 2003, p. 1)

Nations and international organizations continue to monitor progress on the Beijing objectives, which remain a policy framework to guide the slow progress toward gender justice in ICT and other development areas.

FUTURE TRENDS

Beijing 1995, Beijing +5, and Beijing +10 have influenced the development of gender-focused research, analysis, and advocacy in ICT in the International Telecommunications Union (ITU), the UN ICT Task Force, and the 2003 to 2005 World Summit on the Information Society (WSIS). The ITU Task Force on Gender Issues (ITU-TFGI, 2001) developed "gender-aware guidelines for policy-making and regulatory agencies" intended to assist decision makers in their work to ensure that "both women and men are considered in the process" (p. 1). TFGI also found that

> *so-called gender-neutral policies or rules are not enough…women are vastly under-represented in government, business, political and social institutions; men still hold most of the management and control positions in telecommunication companies and regulatory or policy making bodies; regulatory decisions are often made without impact analysis; and service licenses are attributed to companies without equal opportunity policies and are controlled mostly by men. The following are a set of guidelines ... They can be used to ensure that gender-sensitive analysis becomes an integral part of licensing and regulatory activities. Successful implementation of these guidelines requires the development and promotion of such policies within the institutions seeking transformation into a gender-aware environment.* (p. 1)

The United Nations formed the UN ICT Task Force in 2001 to help mainstream ICT into development as a tool for digital opportunities and Millennium Development Goal (MDG) achievement. Gender inclusiveness and awareness have been evident in UN ICT Task Force policy and practice. Members are just under 20% women, and gender issues are regularly addressed in task-force work. The UN ICT Task Force has collaborated with the WSIS Gender Caucus and UNIFEM on the Kampala conference Bridging the Gender Digital Divide through Strategic Partnerships, which produced policy recommendations for gender and ICT including more research on ICT and gender issues.

Society of Women Engineers (2005) research using U.S. data showed that women in ICT education for electrical engineers, programmers, and software engineers progressed slowly from less than 10% of enrollment in the 1970s to 20% in 2000. Data showed similar ratios in these same ICT professions.

Graham and Smith (2005) found U.S. college-educated women represented only 24% of science and engineering (S&E) jobs. Women were underpaid, making 22% less than men. Though gender differentials in pay were even greater in non-S&E jobs, the authors recommended increasing S&E pay overall with policies to reduce gender earning discrimination in S&E jobs because gender inequalities negatively impact the growing information society's need for scientists and engineers.

Women are underrepresented and underpaid in S&E fields outside the United States as well. Data for world nations ranked by the United Nations Development Program (UNDP) Human Development Index (HDI) showed that women held less than half of professional and technical jobs in 26 of the top 50 nations. A comparison of earned-income data for all of the top 50 showed that women's pay ranged between 17% and 63% less than men (UNDP, 2004).

Research has established strong links between ICT growth and economic development, and between gender equality and human development, but ICT growth alone does not necessarily lead to gender equality or human development. King and Mason (2001) compiled substantial research that demonstrated the gendered nature of poverty and its effects, and therefore the need for gender-aware programs to combat poverty. Proactive policies for overcoming gender-equality obstacles in ICT access and growth are more common in ICT-resource-rich countries. Yet it is as important in ICT-resource-poor countries. A gender-sensitive ICT policy, even with scarce ICT resources, can direct ICT applications to the needs of women, their dependent children, and the poor.

A specific policy for gender equality in ICT development is needed if ICT is to contribute significantly to achieving an end to poverty as envisioned in the 2000 Millennium Declaration's eight MDGs.

Gender equality, one of the MDGs, is central to achieving the other goals. Women and their dependent children represent more than two thirds of the world's hungry, poor, and illiterate (UNDP, 2004). Understanding this, the UNDP developed the Gender Development Index (GDI) compiled from economic, education, and health indicators using gender-disaggregated data. The GDI is used to help assess progress toward the MDGs and the advancement of women in all areas of development. Gender-focused ICT education programs can prepare women for more skilled ICT jobs, improve local family incomes, and expand the national ICT skills base, addressing both poverty and gender inequality toward MDG achievement.

Gender research and analysis were part of the civil-society work prior to, during, and after the WSIS during the 3-year summit process. Plou (2005) described how gender relations in the ICT field sometimes reinforce old gender roles and power relationships, sometimes change them, but always require gender awareness in the developing information society. Plou says it is

> *not possible to think of new communication technologies as gender neutral. The absence of women's voices and perspectives in the information society also shows us that power relations in the new media replicate in many ways those in conventional media ... Women's access to information sources and communication channels are crucial if they are to attain democratic participation, respect for their human rights and an equal voice in the public sphere.* (p. 11)

Women are ICT users and content developers, particularly in new media, but are underrepresented among ICT policy makers. WSIS working groups for global policy development included Internet governance in their focus, which addressed technical standards, security, privacy, intellectual property issues, and financial mechanisms, and considered the Digital Solidarity Fund. Though women were well represented among the civil-society participants of WSIS, few women were represented among the thousands of government and business decision makers at WSIS (author's observation at Geneva WSIS; gender-disaggregated data not yet available). Even with much gender advocacy throughout WSIS, gender imbalance in policy making was still evident in the formation of the UN Working Group on Internet Governance (WGIG), which included only 4 women of 40 members (ITU, 2005).

The WSIS Gender Caucus and the NGO Gender Strategies Working Group negotiated strongly for gender to be included as a fundamental principle for action in the policy development process. Gender Caucus convener Gillian Marcelle (2003) said,

Women's perspectives can contribute to making the difference between an Information Economy where gambling and pornography account for the most profitable applcations and a true Information Society that serves human development ... making that leap will require radical transformation of the ICT sector so that all people, including girls and women of all ages, participate fully, not only as consumers but as citizens. This vision requires dramatic changes in the policies, practices and values of the ICT sector and the governance of the sector.

ICT and gender were critical issues debated and eventually included in the World Summit on the Information Society Declaration of Principles and Plan of Action. *The ITU World Telecommunications Report* (2003) focused specifically on how ICT applications could contribute to the achievement of gender equality, the empowerment of women, and the fulfillment of the other MDGs. Research and evidence show that continued attention to gender in monitoring the progress toward all the goals could help catalyze their achievement.

CONCLUSION

Gender-equality strategies, action plans, policy development, and monitoring processes were initiated through the UN decade for women, CEDAW, and the world conferences on women. The 1995 Beijing conference recognized and articulated how creating greater gender equality in ICT access, participation, and capacity building was important to the achievement of sustainable development with gender justice. Gender-equality conditions in the rapidly changing information society are interactive with progress toward ending poverty, hunger, illiteracy, preventable disease, violent conflicts, and social isolation. ICT also plays an essential role in creating informed political participants and decision makers. The Beijing process and the ongoing evaluation of Section J objectives continue to support proactive efforts through WSIS, the UN ICT Task Force, and the MDGs to create more gender-inclusive and gender-sensitive ICT policy-making bodies capable of enhancing gender justice in the information society.

KEY TERMS

Beijing Platform for Action. Section J: Women and the Media: Strategic Objectives J.1., to increase the participation and access of women to expression and decision making in and through the media and new technologies of communication, and

J.2., to promote a balanced and nonstereotyped portrayal of women in the media (United Nations, 1995, pp. 134-136).

Millennium Development Goals: Eight goals agreed on by member states of the United Nations that address the effects of poverty and resource distribution inequities. The Millennium Declaration goals to be achieved by 2015 are the following.

1. Eradicate extreme poverty and hunger
2. Achieve universal primary education
3. Promote gender equality and the empowerment of women
4. Reduce child and maternal mortality
5. Improve maternal health care
6. Combat HIV and AIDS, malaria, and other major diseases
7. Ensure environmental sustainability
8. Develop global partnership for development

World Conferences on Women: International UN-sponsored conferences that addressed gender issues of human rights and equality important to local, regional, national, and international development and cooperation.

- **1975:** First World Conference on Women, Mexico
- **1980:** Second World Conference on Women, Copenhagen, Denmark
- **1985:** Third World Conference on Women, Nairobi, Kenya
- **1995:** Fourth World Conference on Women, Beijing, China
- **2000:** United Nations General Assembly Special Session on Beijing +5, New York
- **2005:** Beijing +10, New York

World Summit on the Information Society (WSIS): A two-phase international summit from 2003 to 2005 organized by the United Nations and the International Telecommunications Union to address the need for international policy and agreement on ICT governance, rights, and responsibilities. The WSIS Gender Caucus is a civil society representative of gender and IT issues.

Biographical Stories of European Women Working in ICT

INTRODUCTION

There is a deep gender imbalance in information and communication technology (ICT) professions which are only about 17% female (compare Valenduc et al., 2004, p. 19) and, simultaneously, an unsatisfied demand for ICT professionals at intermediate and high levels. Although varying in different sectors and countries, a gender imbalance and a skills shortage are common features of the ICT labour market in Europe. This is an obstacle to the development of the knowledge economy and the achievement of social cohesion.

The project WWW-ICT[1] implements an integrated approach to the various aspects and dimensions of gender gaps in ICT professions, covering explicative factors linked to education and training, working and employment conditions, professional and technical culture. Most existing studies have limitations and gaps. They are often limited to classical computer professions, while WWW-ICT intends to encompass new professions linked to new communication technology, also taking into account the vocational training system. Studies of the shortage of ICT professionals are mostly centred on the demand/supply relation, while we focus more on the role of professional models and professional trajectories as a factor of integration or exclusion.

In general terms, employment in the ICT sector has been growing very markedly across the EU in recent years. The sector is increasingly dominated by specialist firms, which have taken over the provision of computing services for client companies. Computer services in the EU are dominated by SMEs; the majority of computer services businesses are micro-businesses employing less than ten employees (Björnsson, 2001). Despite the predominance of micro-businesses, there is a huge concentration of employment in bigger companies. This is the context within which women are employed in ICT.

BACKGROUND

Under-representation of girls and women in computing is a reality and "the reasons why women are not attracted to engineering in great numbers are subtle and complex defying monocausal explanations and solutions" (Adam, 2001, p. 40).

Much of the current discourse around the gender gap in computing is grounded in the debate on women in science and technology that dates back to the early 1980s. This debate revolved around some of the fundamental theoretical difficulties of addressing gender issues. One of these difficulties is to do with a dualistic notion of the world. Criticism of a dualistic construct of gender led to an increasing interest in "difference" (rather than sameness) on the one hand.

On the other hand the first studies of practising women scientists suggested that women choose science for similar reasons as their male colleagues: for the adventure of abstract thought, for the intellectual pleasure that analysing a problem, looking for details, isolating and manipulating variables provide (e.g., Carter & Kirkup, 1990). It was argued that people with the bodies of women do not necessarily have the minds of women. Evelyn Fox Keller (1987) was among the first feminist scholars who used gender not as an empirical category but as an analytical tool to elaborate and concretise the idea of difference and dissent within the sciences. Feminists introduced notions such as polyvalence, epistemological pluralism, and partial translations into the discourse on gender and technology (Wagner, 1994).

Much of this older debate has been absorbed by Judith Butler's notion of gender as "performed" (Butler 1993). It has been taken up by many feminist scholars and, interestingly, extended to technology. Jennifer Croissant argues: "We gender a technology by painting it blue and handing it to a boy. We gender the boy in this interaction, providing a frame of reference for appropriate technological and masculine identity associations and expectations. We of course provide a frame of reference for the girl to whom we do not hand it. We perform with technologies. The technology, with its scripts, schemes, and codes, also performs us in that we become subject to its affordances designed or there by happenstance when we start the performance" (Croissant, 1999, p. 278).

This argumentation leads to a second difficulty of theorising about technology and gender. Assumptions about the technologies that are examined in studies of gender differences are often quite general and superficial. In an early essay on women and technology Knapp (1989) argued that women's ways of doing and thinking are not independent of the object world. Her main criticism of studies of women's relations to the natural and technological world was that these almost exclusively look at the subject—women—disregarding the interactive nature of appropriating a technology. Not only are computers different from other technologies in ways that may affect the ways women and men interact with them. The range of computing applications dramatically expanded during the last decade and with it the range of computing professions. Looking at gender as performance and performed and at computers as highly specialised and varied technologies, has consequences for the method of 'measuring' gender differences. Kay (1992) has argued, "that to fully understand whether gender differences exist in human-computer interaction, a qualitative, contextual, developmental approach should be employed to examine specific tasks. He stresses that without this comprehensive understanding, researchers will continue to identify only pieces of a very complex puzzle" (quoted in Mitra et al., 2001, p. 228). A good example of such a contextual approach is Linda Stepulevage's (1999) reconstructing her own making into a technology expert using the method of autobiographical narrative. She emphasises the actual everyday practices that surround technologies—"people making and doing things." Understanding this "making and doing" is tied to particular locations and contexts (Stepulevage 1999).

It has been argued that in IT as a relatively young field women would not face the same barriers for working careers existing in other fields with a traditional male dominance. Ahuja (2002) argues that this viewpoint does not "adequately take into account the variety of structural and social factors that inescapably and inevitably shape women's careers in IT throughout industry and academia" (p. 22). Noticing a lack of academic studies on gender differences in IT careers she claims that it is important to understand the role of women in the field of IT and "how or if IT differs from other professional endeavours in offering opportunities to women" (p. 21). With that aim she proposes a conceptual framework that covers social factors as well as structural ones influencing women's professional careers in IT.

METHOD

Our qualitative research is based on biographical interviews. The analysis attempts at preserving the biographical aspect of informants' narratives while at the same time looking at more general patterns across individual biographies.

The aim of a biographical interview is to develop an understanding of a person's biography or trajectory—her development as based on opportunities, choices, and individual coping strategies. Crucial concepts are developmental tasks in particular phases of one's life, individual coping strategies in relation to given structures, detours and their implication for the person's biography, transitions (changes of field of work, occupation, life situation, etc.) and life themes (Thomae, 1996) (i.e., topics that emerge in the women's own accounts as crucial for understanding their choices).

The focus of our interviews was on the women's work biographies, with an understanding that these

Table 1. Characteristics of interview partners

Age	from 22 to 55, highest proportion between 31 and 40 years
Qualification	from no ICT related initial training to university degrees in ICT and other subjects
Job Profiles	project management, developing, leading position, Web design, support, marketing, teaching
Firms	large/small companies (more/less than 100 employees)
Status	salaried, self-employed, full-time, part-time
Residence	city/countryside, different regions within the countries

are inseparable from their identity and concept of a good life. Silvia Gherardi's narratives of "women travellers in a male world" come closest to this notion of biographical interviews (Gherardi, 1996). Our interviews are what Flick (1995) calls episodic interviews with a strong narrative character. The main idea is to stimulate a person to tell "stories"—significant episodes in her life that illustrate the whys and hows of important events in her biography. We interviewed 107 women (15 or 16 in each of the seven countries) who were selected according to a set of criteria (see Table 1).

LIFE STORY PATTERNS

The categories we use in our analysis of biographical (life story) patterns are not theory-based but empirical, grounded in the material itself. They reflect some of the colour the women themselves gave to their narratives. We discovered eight main patterns. Each pattern has its own characteristics and its influence on the informants' career paths in ICT.

For this article we have selected four patterns that we found among the women interviewed. These patterns represent different paths into or in ICT professions. All the women belonging to the selected examples manage their working life rather successfully and are on the whole satisfied with their jobs. This selection is due to our focus, namely to emphasise successful careers, in order to find a new quality of research and recommendations. As a lot of existing studies focus on deficiencies, we try to find out positive role models of women, who found a way to manage their professional lives in the ICT sector. To our opinion women's careers are rather defined by their contents, their work practices, interests, opportunities and motivations behind than by obstacles and barriers. Positive examples in this sense give us the possibility of formulating recommendations for "agents of change" more precisely and realistically.

Straight Careers in ICT

Straight careers in ICT can be found in all the different national cultures. They are moved by strong interest in math and sciences and in some cases, looking for a field with good job prospects. This is reflected already in the first educational choices the women take: They follow a technical education from the start, studying computer science or maths or engineering. One of the women says that what she likes about her work is "solving riddles and generally the curiosity to get to the bottom of things."

These women follow one of the predefined trajectories in ICT. They pursue a university career or very consequently climb up the career ladder in the ICT industry. They are extremely hard working. They may have a broad range of interest in their private lives but in their work they are very focused, taking extreme pleasure in mastering the intellectual challenges of their discipline. They have high ambitions and strive to the top. The conditions for being successful—a hierarchical structure, a competitive environment, and long working hours—are accepted. One woman describes that work had become very much a life style. The definition of her identity included late working hours and socialisation over a drink.

Combining Art with Technology

In these careers, it is not technology that is in the foreground but a passion for art or journalism, with ICT entering later as an important tool and skill.

These women work in publishing or advertising. Typical of all these careers is the ease with which the women integrated ICT into their work, developing a passion for both fields, but with their artistic interests and ambitions staying in the foreground. Regarding their life style and way of working they are more artists than computer professionals.

Typically for these careers that are close to the arts is that there are no boundaries between professional work, social commitment and private life.

From the Margins to a Field of Opportunities

There are life stories in which ICT is strongly connected with moving out from one's milieu or region into promising and relatively secure jobs. While in several cases informants come from marginal regions—the countryside in the case of Austria, the South (Sicily) in the case of Italy—in a few other cases it is ethnicity which creates a potentially marginal position from which the women escape. In some cases the women rebel against their home environment. For example for one British woman of Indian ethnic origin the expectations of her parents that she would simply marry and have children in fact gave her a strong motivation to pursue her education and get a good job. However, in most cases the women stay emotionally attached to their original family offering them different kinds of support.

These women are interested in working with technology but not passionate. ICT opens a field of opportunities to these women. Entries into ICT vary. While some of the women studied informatics or something related, others encountered ICT in their first (clerical) jobs, seizing the opportunity to qualify themselves, either through learning by doing (the older ones) or through additional training. One of the prime movers of these careers is the chance to get a well paying job offering security, possibly in a large company.

Building One's Own Environment

Some informants' stories show a strong will and skill to shape their own environment so that it fits their idea of good work and a good life. This is a theme in their accounts which they address explicitly as "building". These women are very self-confident. They have clear goals and set the steps to achieve their ideas and ambitions. Their strong motivation takes them into different directions. It includes going abroad as a single woman to be exposed to other cultures, being in charge of their own life from a quite young age on, founding their own company, carving out their own field of expertise, building things on their own, fighting for a good position.

Some but not all of them come from supporting families. Their parents and often especially the mothers encouraged them to go their own way and get independent. Many of these women also chose supporting partners with whom they share child caring responsibilities and who support their careers. However, there are also women who have to manage job, household and family on their own with no encouragement or help from other family members.

These women define themselves through the content of their work. This may also include broader interests, such as political commitments or artistic interests. Some of the women work as mentors and encourage other women in ICT.

CONCLUSION

Among our interviewees we found a great variety of jobs, entry routes, education as well as motivations and interests in working in the ICT sector. With the life story patterns we tried to capture this diversity without disassembling it into single "influential factors." For the women in our pattern of "Straight careers in ICT" the focus of their motivation is clear on technology. They like the challenges of their work and they are very ambitious. Contrary is the motivation of women who come "From the margins to a field of opportunities." For them ICT offers the chance to get out of their milieu. They usually have a quite "natural" relationship to technology, seeing it as a means to fulfil their tasks, but they are not passionate about it. Women who are "Building one's own environment" are very successful in realising their goals. They actively use the openness of the ICT sector that often lacks predefined job profiles to create their own working environment. The ICT sector is also open in another sense. This can be seen from the experience of women who are "Combining art with technology." These women come from other educational backgrounds and find ICT as an important tool for their work in art, graphic design, or journalism.

Our results from the interviews and case studies show that ICT professions are more varied than often assumed. By using a qualitative approach we were able to understand the motivation of women working in ICT professions from their own viewpoint in the context of their life stories. The result is a lively picture of the situation of women in the ICT sector that sheds light on the women's motivations and needs as well as on the working conditions in the ICT sector. These insights can be used to formulate recommendations[2] that are based on women's experiences from their work practices in ICT professions and that go far beyond the elimination of constraints.

FUTURE TRENDS

The ICT sector is a rather dynamic field. The permanent changes of the sector are tightly connected to the development and the growing of new jobs and new professional areas. Due to the rapid technical improvement it is a challenge to imagine future scenarios. As the ICT sector is a rich area of opportunities for men and women with different educational and qualification backgrounds we notice the necessity of continual research to analyse what is changing. It would be very helpful to improve and update the existing job descriptions and opportunities and to connect research institutions, labour market experts, and counsellors. We observe a great lack of comparable quantitative data as well as a sufficient number of qualitative studies, among them our study is just one contribution to a deeper understanding of the ICT sector. Quantitative and qualitative research should lead to better information about the chances and career options women may have in the ICT sector and so work against the under-representation of girls and women in this area.

KEY TERMS

Agents of Change: Experts and institutions connected to the labour market, the educational and vocational area, industry and politics who should work against the gender imbalance in ICT following the recommendations of research projects. Agents of change are e.g. vocational advisors, counsellors, human resources managers, trade unionists, European and national institutions, social partners, public institutions, teachers, parents and students.

Biographical Interviews: Qualitative interviews, partly pre-structured with a strong narrative character; stimulates a person to tell "stories"—significant episodes of his/her life. Normally the interviewee covers several topics in his/her narration in his/her sequence.

Gender Imbalance in ICT Professions: Various aspects and dimensions of gender gaps in ICT professions, covering explicative factors linked to education and training, working and employment conditions, professional and technical culture.

ICT: Information and communication technologies.

ICT Professions: Rely on professional ICT skills in the ICT industry and in the user industries and services; characterised by the predominance of ICT knowledge; cover a range of tasks including conceptualisation, design, development, implementation, upgrading, maintenance or management of ICT systems and tools.

Life Story Patterns: Typologies drawn from biographical data of the interviews; clusters covering several criteria including career paths, background, education, etc. as well as individual life styles, coping strategies, cultural aspects, etc.; categories of the analysis are not theory-based but empirical, grounded in the material itself. They reflect some of the colour the interviewees gave to their narratives.

Life Themes: Topics that emerge in the person's own accounts as crucial for understanding their choices both in working and private life; can be drawn from biographical interviews. One person may have several different life themes.

2. Conclusions and recommendations can be found in our report (Valenduc et al., 2004).

Boards Need Women with IT

Sonja Bernhardt
ThoughtWare, Australia

INTRODUCTION

In comparison to research on gender diversity on boards, little research has been conducted on the diversity of board skills required for survival in our fast dynamic world, where boards are becoming more responsible for IT strategy, and where skills to optimize technology strategy and execution for maximum business value are in demand.

In this article, the importance of IT knowledge to overall board governance and the value of women with IT skills as board members are explored. A gender profile is developed from the Australian Stock Exchange (ASX), the Equal Opportunity for Women Agency (EOWA) and the Women on Boards 2004 reports. A discussion on relative contributions to board performance is undertaken.

Under the banner of diversity, research into board composition historically has focused on gender issues—where more specifically the lack of women appointed at board levels has been discussed. There is a significant volume of research that verifies the lack of female representation on boards. One example from the EOWA 2004 Census shows that for the top 200 companies listed on the ASX on June 30, 2004, the number of women executive managers in Australia's companies has increased since 2003 by 1.8% to 10.2%, while the number of women board directors has increased since 2003 by only 0.2% to 8.6%. Additionally, 42.0% of companies have no women executive managers and 62.1% of women (but only 31.4% of men) occupy support positions—as opposed to the line positions that ultimately lead to CEO or Board appointments.

This article draws links between IT skills, governance, and women with IT skills at the board level.

BACKGROUND

A view is emerging that the number of technology failures are increasing and that corporate boards in Australia are failing to meet expectations in this area. Various studies show that IT promises are rarely fulfilled, with failure rates as high as 97% being quoted for some projects (da Cruz, 2003).

With this volume of failures resulting in poor organizational performance, combined with increasing attention on corporate governance and a growing realization that IT portfolios are complex, one would expect more enterprises to implement frameworks for IT governance to more tightly focus their IT processes, people, and priorities on achieving business goals. As Broadbent (2004) says, "Lack of director experience in IT, or just plain ignorance, is an increasing problem in the technology age. The business significance of IT capabilities and assets is now very high." Yet Broadbent further explains that very few of the top 100 Australian boards have even one board member with top-level expertise in integrating IT into business processes or envisioning how IT might be changing their industry.

This is reflected by Turnidge's (2002) findings: "In Australia, board skills continue to reflect legal, financial, and engineering backgrounds, often with relatively limited international experience or skills related to the knowledge economy (such as science or technology)." Similarly, research firm Burson-Marsteller (2004) reported that just 5% of the global Fortune 500 companies have a CIO or former CIO on their board.

The call to include technology skills on boards is further supported by Huff, Maher, and Munro (2004) who point out that boards are disinclined to discuss IT and do not comprehend the associated risk. Huff et al. (2004) conclude that:

... emerging technologies and changes in the business environment are redefining the role of

B

corporate boards with respect to IT governance. By asking the right questions, bringing senior IT management into board discussions and recruiting IT talent at the board level, boards can become much more effective in dealing with IT issues.

Increasingly, researchers are making the links between good governance, diversity, and corporate performance. For example, Brown (2003) points to a study that quantifies what many investors intuitively have guessed, that companies with weak governance trail the market.

The call for diversity on boards has been widely discussed. The best boards know how to have a good fight. Diversity in experiences, skills, viewpoints, perspectives, talents, and ideas is a positive (Sonnenfeld, 2002). Diversity is about enriching the leadership platform with different perspectives by having a team of people with different frames of reference." This is further supported by Allen (2003), who states, "companies that will succeed in the 21st century are the ones that will learn and adopt fastest…and that embrace diversity of thought, style, and culture."

WHY IT SKILLS?

Case Study ID550 by Ovum (2003, p. 7) advised that investment in IT:

... requires consistent firm strategies, effective internal and external communication, and a careful assessment of risk. Implementation is often complex, with organizations seeking to balance the needs of multiple stakeholders while ensuring a satisfactory ROI.

Turnidge (2002) supports this view by warning that deciding what is good governance in the technology age is becoming increasingly difficult. With IT having such a direct and immediate effect, boards are as accountable for IT and the associated strategic risks as they are for finances and legal compliance issues. IT governance cannot be designed in isolation from the other key assets of the firm (such as financial and human) and ultimately requires representation at board level.

The argument to include IT skills on boards is strongly supported by Burson-Marsteller's (2004) research, which found that boardrooms need to open their doors to directors with technology skills and competencies in order to unleash innovation and economic growth. Leading companies who had transformed the business landscape by including technology experts on their boards delivered annual returns 6.4% above their industry average.

Broadbent (2004) flags another key driver as being risk management: "IT assets are now just one asset class among others that companies deal with... But increasingly, if not managed appropriately and well integrated into the business they leave organizations exposed to huge risk and competitive disadvantage." Broadbent further warns that boards do not always have expertise in "envisioning how better IT-enabled business can improve positioning." This skill and risk profile is reflected by a statement made to Broadbent at a 2004 presentation: "I don't want to see my company in the headlines for the wrong reasons. We suspect we are at risk but we are not sure exactly how to assess that." The author suggests that IT expertise at board level might address this.

The issue can be brought down to risk, as Siwik and Randall (2004) indicate:

The emerging standards of corporate governance are forcing businesses to abandon their traditional silo-based risk management approach. As we have seen with Enron, silo-based risk management permits business leaders to point the finger elsewhere with nobody ultimately accepting responsibility … Every company, regardless of size, should work to measure, manage and monitor risk in a coordinated manner. Businesses are a complicated blend of knowledge, technology, people, processes, and capital, and the only proper and effective perspective is a comprehensive and strategic one.

Thus, we can draw the conclusion that if board governance is to be effective within our changing environment where strategic issues include the significant financial and operational issues associated with IT investment, then board members must demonstrate an ability to understand the implications of IT decisions. IT expertise belongs on the boards of companies alongside traditional financial, legal, and general management skills.

WHY WOMEN?

There is no question of whether women are qualified: to be board members, CEO's, scientists or other professional roles. That was decisively answered years ago: some are and some are not, just as some men are qualified and some are not.

Research indicates one compelling reason to appoint women as board members: improved performance/outcomes. Despite this, Australia lags behind the USA and Canada, where 86% of US Fortune 500 companies and 62.4% of the Canadian Financial Post 500 have at least one woman in an executive management position.

This lag is demonstrated by the EOWA 2004 Census. It shows that women, although 43% of the total Australian workforce, currently account for only 3.2% of top executives, with only 5% in the line-officer pipeline. In addition, according to the ASX in 2003, women held only 8.4% of board directorships in the top 200 ASX companies, and 47.3% of Australian companies had no female directors. Therefore, there is still a long way to go within Australia towards recognizing the value of appointing women at board level and the resulting improved performance.

The question to ask is, does selecting on gender necessarily result in improvement in the business areas that count? This question was addressed by Adler (2001, pp. 4-5), who tracked 215 Fortune 500 companies, comparing their financial performance to industry medians. He found that "companies that smash the glass ceiling also enjoy higher profits." Furthermore, "the companies with the highest percentages of female executives delivered earnings far in excess of the median for other large firms in their industries."

Brown, Brown, and Anastasopoulos (2002) findings support those of Adler. It tracked the financial well being of Canadian firms with two or more women on their boards in 1995 to see where they stood six years later. It found that firms with women board members were much more likely than companies with all-male boards to be leaders when ranked by revenue or profit.

These findings are reflected in Australia in the 2004 EOWA census and the 2004 Women on Boards research, which indicated a significant trend of better financial results for companies with female directors.

Other studies show that boards with more women use more non-financial performance measures such as more regularly reviewing customer satisfaction, employee satisfaction, gender representation in management, improved community relations, innovation, and connection to a wider customer base. This shows that appointment of female board members broadens the focus of issues that boards consider. While these studies do not make a theory, they do strongly suggest a positive relationship between the presence of women on boards, good corporate governance and financial performance.

Simply put, board diversity, specifically an increase in the number of women board members, is good business. It strengthens governance, promotes marketplace competitiveness, builds employee morale, and is a source of positive Public Relations for shareholders and the public. In addition, improved performance in those areas adds up to improved financial performance (Women on Boards, 2003).

WHY WOMEN WITH IT SKILLS?

Sonnenfeld (2002, p. 9) implies some interesting questions: "How well can board members with mostly similar experiences and backgrounds ensure that the full range of strategic risks facing their organization have been identified?" and "How can board members with similar perspectives and frames of reference truly assign a value to risk management and oversight?"

The question of assessing risk begins to be addressed by Brown, Brown, and Anastasopoulos (2002) who found that more female than male directors pay attention to audit and risk oversight and control; that women, more than men, tend to consider the needs of more categories of stakeholders; and that women, more than men, tend to examine a wider range of management and organizational performance. In addition, the research found that 94% of boards with three or more women (but only 58% of all-male boards) insist on conflict-of-interest guidelines.

With respect to IT knowledge, the challenge is to locate board representatives that are able to ask the right questions to unravel the "secrets" of IT in such a way that other board members can appreciate the associated risk and business imperatives without the need for technical detail, acronyms, and other jargon. Craig (2004) flags that "the research literature shows that there are many people in Australia who have established that they believe passionately about the need for diversity ... They consider that women can bring a different perspective and alternative skills that will help create better systems for all." This is further supported by Jamnik (2004), who advised that in the knowledge economy better decisions would be made by including women in the decision process.

Thus, the preceding discussion implies that if women with IT skills were appointed at board level then:

- More attention would be paid to associated IT risks
- Implications of IT activity would be considered enterprise wide, encompassing a wider field of stakeholders
- Better decisions would be made
- IT strategy would be linked to business objectives
- Board performance would be improved
- Company financial performance would be improved

ISSUES

Where are the Women?

Anecdotal evidence in Australia is that those seeking board members advise, "they would have appointed a women but could not find one," which raises the question of "Where are the Women?"

Key issues that need to be considered when seeking suitable women for board appointment are:

1. Women are not visible at executive levels
2. An increasing number of women are departing corporate firms to establish their own businesses
3. The majority of firms (up to 97%) within the Australian IT industry are small (less than 20 staff) not publicly listed firms (ABS, 2002). This trend appears evident globally.

Traditionally, board recruiting in Australia has tended to be fairly informal, conducted largely through existing directors' networks. Historically this has appeared to work, but it naturally limits the pool of potential candidates. The author suggests that despite frequent claims to the contrary, there are talented individuals who qualify as potential board nominees. The problem lies in the fact that they may not be well known within directors' networks because they are not ex-CEOs or Directors of public companies.

This implies changes are needed to recruitment practices of boards for those seeking to appoint women to boards and more specifically women with IT skills. Such changes would incorporate actively seeking women who may not be visible in the top 500 firms, but who possess the required skills and abilities but have opted out for smaller organizations or set up their own businesses (Allen, 2003).

More specifically, boards seeking women with IT skills ought to adopt a strategy of aligning with industry associations that are attracting women with business and IT skills. Interestingly, the past two years has seen an increase within Australia of projects and programs targeted at attracting, registering, and skilling up board ready women (AWISE, 2005; WIT; Women on Boards, 2003). Therefore, the pool of potential candidates is increasing, and the issue is looking in the right places.

Women and Profits

More research is needed on cause and effect re the better financial performance associated with appointment of women on boards: particularly in gauging if it is due to the impact of women on boards, or if successful firms tend to be less conservative and more innovative, and more likely to appoint women.

Gender vs. Individual

While a link between greater board diversity and company performance has been established, research is required to determine how much of this is due to more balance in gender etc. vs. better selection of individuals with the right skills outside of the reigning social group or network.

FUTURE TRENDS

Fundamentally, this article is proposing three future trends:

1. Board governance to incorporate IT strategy
2. Appointment of people with technology skills, and more specifically women with IT skills, onto boards
3. Modifications to the board appointment recruitment process to increase the visibility of women who are not current or ex CEOs

This is about improving company performance, where a genuinely representative board brings together individuals with different experiences, skills, and points of view. This suggests the need for careful consideration in the future of the board composition, to better meet not only business needs of the company, but with more emphasis on the skills required for understanding technology impacts and directions.

CONCLUSION

The focus of a significant volume of literature about diversity on boards has been on gender issues. This article broadens the gender debate to include skills and learning/communication styles, more specifically the inclusion of IT skills on boards. In our dynamic world where boards are becoming more responsible for IT strategy and investment, gender balance is only one aspect of this larger issue.

This is summarized by Slater (2003):

The board in the business environment in this century might be characterized as smaller, leaner, and more diversified, with technology comprehension, business acumen and an energetic entrepreneurial drive.

It is not rocket science. We draw the conclusion that to enhance the ability to succeed in the 21st century, IT skills belong on the boards of companies alongside traditional financial, legal, and general management skills.

The facts are:

1. There is strong evidence that indicates that diversity (specifically appointment of women) enhances board performance
2. We are in a fast paced society where technology is an underlying infrastructure across many businesses and boards need to pay attention to IT governance
3. There is already an "invisible" pool of talented women with IT skills suitable for appointment to boards: recruitment strategies just need to source these women to amplify the impacts and enhance board diversity and performance

KEY TERMS

Board/Board of Directors: Includes commercial, government, and not for profit boards, and board members refers to executive and non-executive as well as voluntary and ex officio appointments.

Board Composition: The mix of specific skills in areas such as marketing, finance, law, risk management, industrial relations, asset management, communications or public relations, economics, IT, change management, and broad strategic awareness.

Corporate Governance: Promoting corporate fairness, transparency, and accountability. Governance is essentially about ensuring that business is conducted properly. It is less about overt control and strict adherence to rules, and more about guidance and effective and equitable usage of resources to ensure sustainability of an organization's strategic objectives.

Diversity: Refers to more than just representation of diversity of skills and experience in the composition of the board. The board, in its directorship base, should also possess a diversity of styles and views. Diversity refers to differences across a range of demographic attributes including gender, age, religion, ethnicity, national origin, physical and mental ability, level of education, marital and family status, and sexual orientation.

IT Governance: Provides the framework and structure that links IT resources and information to enterprise goals and strategies. As defined by Broadbent (2002) IT governance specifies the decision rights and accountability framework to encourage desirable behavior in the use of IT. It is not about IT management and the detail of particular IT decisions and their implementation, rather about the arrangements for who makes critical decisions and who is accountable for them.

IT/Information Technology: A term that encompasses all forms of technology used to create, store, exchange, and use information in its various forms. Reference to IT/Information Technology is deemed to include the "C" of "ICT" information and Communications technology, which is the technology used to handle information and aid communication.

Knowledge Economy: The Department for Trade and Industry's (1998) flagship policy document *Our Competitive Future: Building the Knowledge-Driven Economy* states that:

[a knowledge based economy] is one in which the genderation and exploitation of knowledge has come to play the predominant part in the creation of wealth. It is not simply about pushing back the frontiers of knowledge; it is also about the more effective use and exploitation of all types of knowledge in all manner of activity.

ROI: Return on investment.

Bridging the Entrepreneurial and Technology Gap for Women

Briga Hynes
University of Limerick, Ireland

Ita Richardson
University of Limerick, Ireland

INTRODUCTION

In the early 21st century, there continues to be an unbalanced ratio of males to females both studying for and in technological positions in Ireland. For example, computer science is a relatively new discipline. It was hoped that in such disciplines women could establish themselves and would "break new ground in professional access and equity for women" (Pearl, 1995, p. 26). This has not been the case. It is generally accepted that about 20% or less of places in engineering and technology (E&T) courses in Irish third-level colleges are filled by women (Richardson, O'Brien, & Moore, 2002).

Furthermore, as a result of low levels of female participation in E&T jobs, there are corresponding low levels of female participation in technical self-employment. Women in Ireland are 2.6 times less likely to start a business than their male colleagues; females in Ireland are more averse to risk taking and are cautious (Fitzsimons, O'Gorman, & Roche, 2003). This can be attributed to gender-generic factors (Hynes, 1996). These factors include personal profiles, situational and personality characteristics, and self-belief that manifest as barriers to female participation in enterprising activity (GEM, 2004). To overcome this scarcity of technological knowledgeable females in self-employment, it is necessary to determine the source of this problem. This is achieved by interlinking research in these two topics, which are generally researched independently, but when researched together, they add value to and inform the debate in the Irish context. The research involves the identification of the sources of these barriers with a view of devising corrective interventions. It is suggested that the role of education is instrumental in overcoming these barriers. Consequently, in this article, we propose a framework that can be modified to suit the needs of female students.

BACKGROUND

In the Irish context, the number of females entering technology professions is still very low. In a recent report from the European Commission (2003), it is stated that "men graduates are consistently more likely than women graduates to be graduating from Engineering programmes, and, with the only exceptions of Belgium and Spain, from Science, Mathematics and Computing programmes" (p. 45).

Current Status of Female Participation in Engineering and Technical Education

In the second-level school system in Ireland, there has been an improvement in the uptake of science subjects among women. In 2000, 47% of those taking leaving-certificate higher level mathematics, 30% of those taking higher level physics, 56% of those taking higher level chemistry, and 71% of those taking higher level biology were women (Forfás, 2003a). The numbers of women in other subjects that are the basis for further study in E&T are much lower: applied mathematics (21%), engineering (4%), technical drawing (8%), and construction studies (5%). Computer science or information technology is not offered at the leaving-certificate level in Ireland. Furthermore, the number of females entering E&T courses in the third level remains low. In

2002, in engineering or technology courses, one female accepted a place for every four males (McDonagh & Patterson, 2002).

At the postgraduate level, this downward trend continues. According to Forfás (2003b), only 17.1% of PhD researchers and 20.9% of non-PhD researchers are female. Within the engineering, manufacturing, and construction category, 22.2% of postgraduates were women (European Commission, 2003). On the positive side, while women constitute 39.6% of higher level graduates overall within Europe, their numbers are increasing by an annual average of 4.8% as opposed to 0.9% for men. The growth difference in Ireland is not as great with 6.9% growth for women and 6.0% growth for men (European Commission).

Implications for Business and Society

Although women's influence on project teams can cause significant changes in the design of products, their numbers are too small (even at 20%) to have a continuous significant effect. The construction of infrastructure, both physical and technological, is being carried out mainly by men, yet women make up over 50% of the population (Central Statistics Office [CSO], http://www.cso.ie). The late Anita Borg from Xerox has been quoted as saying, "If women were more involved in creating new technologies, cars would have a place for you to put your handbag" (Smith, 2002, p. 1). Florida (2002, p. 249) argues that "diversity and concentration work together to speed the flow of knowledge." Or, as Trauth (2002, p. 102) states, "women in the IT profession, as a group, are different from men, as a group, in the profession, albeit for sociological rather than biological or psychological reasons." Ultimately, the diversity offered by female influence during technological design is often missing.

Technology-based policies influencing society are being made without women's input. Issues such as privacy and security, the misuse of the Internet, and the location of telecommunications infrastructures are significant. Women currently in the engineering and technology workforce can exert some influence, but women's influence must become more far reaching. Indeed, in Ireland, although there is a government target to have state boards composed of at least 40% women, the figure is closer to 25% (NDP Gender Equality Unit, 2000)

For individual women who are turning their backs on technological careers, the effects are very significant. As the statistics show, the lack of mathematics skills is not a recognised hindrance. Individuals are missing out on rewarding positions offering a variety of tasks that include working with people. These jobs are often highly paid (CSO), with new learning opportunities always possible. Contrary to common belief, it is unusual for careers in this area to be "geeky," antisocial, and boring. The absence of women participating in these disciplines results in lost career opportunities for women, and on a broader scale, results in lost opportunities for industry and the general economy of Ireland.

This loss is further encountered within entrepreneurship. The potential for women to become entrepreneurs in engineering and technology, the high-tech industry, is lost. Women who are capable of pursuing technological careers in established firms fail to transfer this knowledge to the establishment of their own businesses, unlike many of their male counterparts.

Current Status of Female Participation in Entrepreneurship and Small-Business Ownership in Ireland

Statistics suggest that the level of entrepreneurial participation by Irish females at 3.7% is lower than in the United Kingdom or United States (Fitzsimons et al., 2003). In Ireland, women make up only 15% of Irish entrepreneurs, and entrepreneurial participation by women halved between 2001 and 2003 while that of males declined by 26%. This report also found that more educated women are more likely to engage in entrepreneurial activity. While the intention to start a business is high among females in relation to males, the follow up and transition to actually starting a business is much less for females (Fitzsimons et al., 2003).

This compares to an average of 29% of females in Europe who are engaged in enterprising activity (Observatory of European SMEs, 2003). In 2003, Ireland ranked 6th among the 22 OCED countries in terms of women who were thinking of starting a business. However, this ranking slips to 17th place when comparing the percentage of women who had actually started a new business (GEM, 2004). Why is this the case? And more importantly, what can be done to remedy this situation?

Research studies in Ireland (Goodbody Economic Consultants, 2002; Henry & Johnson, 2003; Limerick City Enterprise Board, 2003) have attempted to identify why this low participation exists and what the perceived barriers are that females encounter in managing their own businesses. Goodbody Economic Consultants found a number of common factors including social conditioning and expectations of females in society; the perceptions of the demands of running a business; glass ceilings; a lack of female role models; the low proportion of women pursuing science, engineering, and technology programmes; a lack of self-confidence and self-belief; and difficulties in reconciling work and family life for females as all contributing to low participation.

Henry and Johnson (2003) found that the main barriers and challenges to self-employment were associated with funding, the entrepreneur not being taken seriously, and time management. The time-management issue centred on the need to balance business activities around family demands and circumstances. These findings are also reflected in research completed by the Limerick City Enterprise Board (2003). It found that female entrepreneurs indicated that their business choice was related to their interests, hobbies, and values. Factors such as previous work experience did not rate highly as influencing their choice or type of business venture.

This research found that females tended to be less confident and assertive in the initial researching and selling of their business idea and in the acquisition of resources. Respondents did not have previous management positions prior to start-up, which they felt was a disadvantage. However, it can also be argued that many males entering self-employment do not have management experience or skills either; however, it is not an issue that is perceived as a barrier by them in the development of their business. This relates to the broader debate on the role of females in the workplace and in management positions, and how in many instances current management roles, practices, and values are still male dominated. The female entrepreneurs considered that they could benefit from enhanced management skills and confidence in the ability to network and sell not just the idea, but themselves in a confident manner.

Research would also suggest that these issues influence the type and profile of new businesses established, with very few new businesses established by females in the technology and engineering fields. Research by Goodbody Economic Consultants (2002) and the NDP Gender Equality Unit (2000) suggest from their respective research that females tend to start businesses in the general-services, tourism, and financial-services sectors, while men tend to start more businesses in manufacturing, construction, and technology areas. A range of personal profiles, personality characteristics, and educational and industrial work experience greatly influences the attitudes, perceptions, knowledge, and exposure to self-employment and the choice of career options for females (GEM 2004). Once identified, the challenge for policy makers and educationists is to determine how these obstacles can be best addressed and overcome.

FUTURE TRENDS

We suggest that targeted education programmes that incorporate and integrate both technology and business knowledge and skills requirements are an important starting point on which to change attitudes and behaviour currently militating against female participation in entrepreneurship.

Bridging the Gap: Education to Encourage More Female High-Tech Entrepreneurs

Education (in its broadest sense) should stimulate enterprising behaviour as it provides individuals with a sense of autonomy, independence, and self-confidence (Garavan & Ó Cinnéide, 1994). These qualities are important when starting a business (Deakins & Freel, 2003). Education broadens the horizons of individuals, thereby making the student better equipped to perceive opportunities in the environment around them. Education should make people aware of alternative career choices, and one such alternative should be self-employment. Findings reported by GEM (2004) suggested that the

Irish educational system did not have a developed or focused strategy to expose students sufficiently to entrepreneurship as a career alternative.

Technology Education

Within engineering and technology programmes, it is important for the student to be educated in a variety of subjects ranging from mathematics, to engineering, to design. Students must be able to move from a fundamental understanding of their subject, the underlying science, to its conversion and practical application into a product that is useful to and used by the end user. Different foci of technology can be studied. For example, in studying information technology, different viewpoints can be taken such as the study of hardware, software, and/or the societal effects of information technology. Our experiences as teachers and researchers in information technology and entrepreneurship indicate the need for the introduction of new subject areas focusing not just on knowledge, but also on skill acquisition. Group work providing students with the basis of working in teams is important. Problem solving and decision making are other skills that need to be developed.

Entrepreneurship Education

Entrepreneurship education should adopt an integrated approach and make enterprise courses available across disciplines (Fleming, 1999; Hynes, 1996). This interdisciplinary approach encourages the use of interdisciplinary student teams comprised of non-business and business students working together. This interaction provides students with a very real-life experience and enhances not just knowledge acquisition, but also skills development in the areas of communication, negotiation, conflict management, and project and people management.

Entrepreneurship education is process driven, and the process needs to consider three central players: the students, teachers (trainers), and business community (Daly, 2004; Hynes, 1996). Linkages between all three ensure programmes are balanced between theory and practice. As the three players have evolving and changing needs, all of which must be considered, this requires a level of integration and flexibility and the delivery of effective programmes.

Integrating Entrepreneurship and the Technology Disciplines: The Issues

Programmes in entrepreneurship and technology are often delivered separately. This article proposes an integrated education programme incorporating both these disciplines, focusing on how more females may be encouraged to choose E&T education and ultimately pursue high-tech self-employment as a career option. We propose linking both sets of programmes, thus providing the student with technical and subject-specific knowledge with the complementary skill sets of entrepreneurship.

The aim of entrepreneurship and technological education should be to encourage female graduates who are capable of being innovative and can recognise and create opportunities, take risks, make decisions, analyse and solve problems, and communicate clearly and effectively to evaluate self-employment as an alternative career option.

Proposed Programme Framework

Our involvement in programmes providing technology to women (Richardson et al., 2002) and in entrepreneurship education (Hynes, 1996) has given an insight into the educational requirements for female E&T entrepreneurs. Starting a new business involves more than the development of a final product or service; rather, it encompasses a series of stages, which link together, that are managed in a subjective way by the entrepreneur and are influenced by a number of factors both personal and situational. From an E&T perspective, students must bring prior knowledge and learn new content. The proposed educational framework and process model, adopted from Hynes, acknowledges these elements, and in doing so, directs the design of a more appropriate and targeted educational initiative to foster increased entrepreneurial behaviour in female E&T graduates. Hynes proposed that initiatives for women must focus on more than tangible learning outcomes. They should focus on personal development, confidence building, self-esteem, and general decision-making and management skills. It is considered that these skills are very important to encourage greater female participation in both technology and engineering disciplines and self-employment.

Figure 1. Proposed framework of high-technology entrepreneurship education (Source: Modified from Hynes, 1996)

Inputs	**Process**		**Outputs**
Students	**Content Focus**	**Teaching Focus**	**Professional/ Technological**
Prior knowledge base Motivation Personality Needs/interests Independence Attitudes Parent influence Self-esteem Values Work experience	Science/mathematics Information technology Engineering design Usability Entrepreneurship defined Intrapreneurship Innovation New product development Idea generation Market research Finance Production technology Intellectual property rights People management Teamwork Business Marketing	Didactic (reading/lectures) Skill building (case studies, group discussions, presentations, problem solving, simulations, teamwork, projects) Discovery (brainstorming, personal goal setting, career planning, consultancy)	Personal (confidence, communication) Knowledge (enterprise, initiative, self-employment, business, management and market skills, analytical, problem solving, decision making, communication, presentation, risk taking) Career (improved knowledge, broader career options, broader and less structured career perspectives).

The modified process model includes high-technology content (Figure 1). We can see that, mainly through the teaching focus, these skills must be integrated with and not separated from the content focus, thereby converting the students' inputs into professional technological outputs (both tangible and intangible). The proposed framework indicates the key areas to consider, and acknowledges that it may need to be modified to accommodate the specific characteristics of the different target groups, different regional characteristics, and different environmental conditions. The flexibility to adapt the framework to the needs of the situation is a key determinant in its effectiveness.

The personal profiles and personality characteristics of the inputs or students are important and should be defined before the content or teaching focus is finally decided upon. It is at this stage that many of the aforementioned obstacles discussed can be accounted for and accommodated in the content, teaching, and delivery processes. A useful method of ensuring that these details are collected is through the completion of an entry questionnaire. This assists the students to determine their own levels of self-awareness and interest in both disciplines.

As female participation in E&T is not occurring naturally—that is, women are not considering E&T as a career option at the same rate as males—there must be a continued focus on the promotion of E&T to women through such initiatives. Otherwise, significant female participation in high-technology entrepreneurship will never happen.

The content focus provides students with an understanding of the technology topics and the stages of the entrepreneurial process. Other content-focus topics, such as people management, teamwork, business, marketing, and management, are often not associated with the study of E&T. The provision of these within entrepreneurship modules will add value to the knowledge of necessary business subject areas and also develop the skills base to encourage more enterprising behaviour.

The teaching-process aspect is critical to ensure that the identified skills and knowledge objectives are achieved. The teaching focus should also take into consideration the obstacles that militate against female participation in engineering, technology, and entrepreneurship. Therefore, the focus should combine both formal and informal teaching methods, and also encourage topics such as problem solving and career planning. The teaching focus should provide students with the knowledge of not just what to do, but how to do it. The teaching can be delivered through the use of case studies, the inclusion of guest lecturers, and the use of role-plays and project work, all of which have been effective in our teaching to date.

The combination of content and teaching elements provides students with an understanding of the stages of the entrepreneurial process. The completion of a business plan in an interdisciplinary team provides the student with a practical and realistic insight into how self-employment in the E&T field can at some stage be a career option for them.

Given that the inputs, content, and teaching are provided through the initiatives discussed in this article, we expect that a combination will give the desired outputs. We therefore consider that the integration and linking of these types of programmes will result in key initiatives through which we can provide the inputs through the effects of E&T initiatives, and the content and teaching focus through entrepreneurship education. This will provide female graduates with personal, knowledge, and career requirements, facilitating them to become high-technology entrepreneurs in the E&T arena.

We are aware of the need for positive interest and entrepreneurship education for both male and female students. While the same type of programme can be applicable and relevant to both genders on a generic basis, the promotion of female entrepreneurship in E&T sectors requires some level of customisation in content and delivery methods to cater for the more specific attitudinal and confidence issues that tend to be more prevalent with female students. We suggest that programmes to foster female E&T entrepreneurship can be adopted to suit most school curricula and can have positive benefits for both disciplines.

CONCLUSION

This research adds to the ongoing debate on the issues and barriers associated with female entrepreneurship in the high-technology sector by addressing what are considered the source of the problems. It further discusses how the promotion of E&T initiatives can support the development of high-technology female entrepreneurs. Suitable interventions catering for both disciplines can and should be developed. In the development and implementation of the process framework for high-technology entrepreneurship education, we have considered some of the key priority issues that need to be addressed in future entrepreneurship programmes for female students.

The development of such initiatives could have broad applications, may assist in reversing the trends presented in Fitzsimons et al. (2003), and can contribute in the long term to the pool of female Irish entrepreneurs willing to and capable of starting high-technology companies.

KEY TERMS

Education: Education broadens the horizons of individuals, thereby making students better equipped to perceive opportunities in the environment around them.

Engineering & Technology Courses: Courses whose focus is an area of engineering and/or technology. Such courses include, for example, electronic engineering, computer science, information technology, and manufacturing engineering.

Entrepreneurship Activity: The number of individuals who consider starting a new business and those who actually start and manage an established small firm.

Entrepreneurship Education: Process of providing students with the understanding, knowledge, and skills required to develop and manage a new business.

Glass Ceiling: The unofficial barrier that is perceived as making it more difficult for minority groups, such as women, to achieve career advancement to management.

Role Models: In this context, people who younger individuals or those with career aspirations can identify with, look up to, or get advice from.

Second-Level School System in Ireland: Students enter the second-level system from 12 years of age onward. Students complete a minimum of 5 years of study and exit with a leaving-certificate qualification, usually in at least 7 subjects. These subjects normally include Irish, English, mathematics, often a European language, and three other subjects chosen by the student. The students can write either a higher or ordinary-level paper in each subject.

Technology Education: Process that develops the student's fundamental understanding of the subject—the underlying science—into a product that is useful to and used by the end user.

Career Management Concerns for Women in IT

David M. Kaplan
Saint Louis University, USA

Fred Niederman
Saint Louis University, USA

INTRODUCTION

Frequently researchers cite the perceived masculinity (Ahuja, 2002; Muryn Kaminiski & Reilly, 2004; Trauth, 2002) of information technology (IT) jobs as one of the main reasons that more women are not in the field. Such a diagnosis, while helpful for strategizing plans to attract new women into IT, does not address the needs and concerns of women currently in IT positions. These women are already aware of the degree to which IT is a masculine profession. They have entered the field in spite of this because they have a natural affinity for the work, found a niche that is comfortable for them, or developed a coping strategy. While these women may have overcome important barriers to enter the profession, entry does not constitute the last hurdle that they will have to face in their careers.

Certainly, the path for women intending to make a career in IT is an uphill one. One only needs to look at the disparity between the numbers of men and women working in the industry (United States Census Bureau, 2005) to sense that the playing field is not level. While acknowledging that women are overtly discriminated, it's important for women to become aware of the unintentional ways they are discriminated against, how they may inadvertently contribute to this, and possible methods for overcoming it.

Specifically, the authors will discuss how inadequate social networks, skill obsolescence, and limited vertical/internal job mobility present challenges to career success. While not unique, these challenges are more tangible and pervasive barriers to career success for women in IT. Also, while other scholars have identified similar career hurdles for women in IT (Ahuja, 2002), the current discussion differs from past scholarship in several key areas. First, these issues are discussed with an emphasis for women once they have started their careers and not their initial career choice. Second, each section includes a vignette that provides an example and context explaining the underlying processes. Third, the paper goes beyond diagnosis and explanation to offering specific strategies for overcoming these barriers.

INADEQUATE SOCIAL NETWORKS

The local team (it doesn't matter what sport) just played an incredible game, Tom who is a big sports fan can't believe they pulled it out and are in the playoffs, as he sits down to the meeting with Sally and their manager, Alex, he asks if either caught the game over the weekend. Sally says no. But Alex and Tom start talking about key plays, bad calls, and their favorite players. Eventually they settle down to the meeting, but Alex decides to continue the conversation over lunch, as Sally wasn't a part of this conversation she wasn't invited. Its not that Tom and Alex don't like Sally or don't think she's talented, it's just they're talking sports so don't think to include her along. Unfortunately for Sally, Tom and Alex get into the habit of going out to lunch. As a result, Sally misses critical opportunities to bond with her manager and doesn't build the same relationship with Alex that Tom has. So when it comes time for promotion or assigning an important project, to whom does it go? While there is no conscious intent to discriminate against Sally, it is just that Alex, like most people, wants to see his friend do well. So all else equal, Tom is more likely to get the high profile assignment or promotion. Further, seeing the old boy's network at work once again, *Sally is more likely to feel disenfranchised and more apt to consider leaving the organization.*

While this vignette describes a single example, the basic facts are repeated over and again for both men and women. Companies like hiring and promoting individuals with personal connections because those personal connections provide greater assurances that the individual will fit into the culture. These personal connections, even if not work related, can also create a sense of mutual obligation and trust. Assuming that all else is equal in terms of work quantity and quality as well as future "promotability," why take a chance on Sally when the management team already likes Tom? This similarity selection bias has been explained and documented in both the psychological (Schneider, 1987) and sociological (DiMaggio & Powell, 1983) literatures.

Because of the gender composition of the workforce, this represents a particular problem for women in IT. The percentage of women among all IT workers varies between 20 and 30% for most IT jobs (US Census Bureau, 2005). Accordingly, this classifies women in IT jobs as a minority rather than tokens (Kanter, 1977). This means that there should be sufficient number of women to create gender-exclusive networks, making it more challenging, but not impossible to create such networks. Women in organizations or professions where they are tokens would, ironically, not have the luxury to create such networks and may by necessity create cross-gender relationships.

So women can improve their outcomes by starting to read the sports page, right?

Not exactly/completely. Developing an interest in sports won't help unless the rest of the conversation changes. Women need to be more strategic when deciding with whom they should develop relationships within their organization. Research has shown that women, in male dominated organizations, and minorities who have more demographically diverse networks generally experience greater levels of career success (Cox, 1994; Ely, 1994; Ibarra, 1995).

Managers can also help compensate for this phenomenon. One organizational strategy would be to take advantage of the potential of diversity training. If men and women in the organization become conscious of how their default conversational topics can impact careers, they have a greater chance of changing communication patterns and thus promote cross-gender relationships (DeJanasz, Dowd, & Schneider, 2002). This requires that organizations develop training strategies that go beyond mere compliance issues.

Another way that an organization can help overcome this networking problem is by developing a mentoring program (Cox, 1994). Research has shown that mentoring improves the career outcomes for the protégé. Mentors improve employment outcomes for individuals by helping their protégés with career planning, acting as role models, navigating organizational politics, and providing the protégé with access to their own social networks. While the networking function is only one of many ways that the mentor contributes to the career success of the protégé, it's the function most relevant to the current discussion.

While mentoring programs have, in general, been shown to be effective, the overall success rate of formal mentoring programs is relatively less than informal ones (Chao, Walz, & Gardner, 1992; Ragins & Cotton, 1999). Unfortunately, given the issues involved in the formation of personal networks the likelihood of large numbers of women entering into informal mentorship programs with men seems remote. Still, organizational intervention with a formal program is preferable to no program.

While mentors and protégés that share common interests will develop stronger relationships, organizations should be careful about the obvious matching of men with men and women with women. This is not to say that a woman would not make a good mentor for another woman, just that a main reason for instituting such relationships is to help overcome the cross-gender networking problem. Selecting women as mentors is perfectly okay as long as the potential mentor has a diverse/powerful social network. Otherwise, all else equal, a potential female protégé could arguably benefit more by being paired up with a male mentor, as this would address the important cross-gender networking concerns.

SKILL OBSOLESCENCE

While who you know might get you into a specific position, what you know will keep you there. Thus another key challenge for women in IT is the threat posed by skill obsolescence. Again, this is not a problem that can be fixed by influencing the choices and academic direction of girls and young women. The rate at which skills become obsolete is faster for IT workers relative to other professions, making this a greater threat to their careers.

While advanced training is the obvious answer to this problem, the implementation is not that simple. The provision of training in IT is complicated by the tendency that required skills are either general (Becker, 1975) or industry-specific (Derek, 1995) in nature. This means that you can take the programming language you learned at job A and take it with you to job B. Because such training improves the mobility of the individual, employers are reticent about providing it. After all, companies want to protect their investment, in this case your increased skill base. Organizations would not last long if they lost all their best employees as soon as they paid to train them.

One way that organizations have dealt with the portability of such skills is to adjust the investment function so that the cost burden is shifted to the employee. At the most basic level, this is seen in the expectation that applicants for entry-level positions already have bachelors' degrees. Once hired, companies shift the costs to the worker through a variety of mechanisms such as scheduling the training session for non-work hours. Although the employer may pay the tuition costs of training that takes place during non-work hours, they shift costs to the individual by making him or her attend during non-compensable time. This saves the employer from losing productive employee time during the workday and requires the employee to show commitment through a time investment into the training program. This explains why so many training sessions take place in the evenings or on weekends.

So why is the "generalizability of training" a gender related issue? Let's consider Tammy's story.

Tammy works in a technical support position at her company. Because of her high ratings, Tammy is asked if she will attend the vendor's training course. Tammy is flattered, and wants to say yes, but has a problem. The training sessions start at 6:30 and are held an hour east of her office, and that doesn't give her enough time to pick up her kids at day-care. Even assuming that she could work through lunch and leave an hour early, who is she going to get, much less how is she going to pay someone, to watch her kids while at the training? After spending a couple of days trying to figure out a solution, Tammy reluctantly has to go to her supervisor and explain that its not possible for her to attend the training course.

As this scenario shows, it is here, in the scheduling of training programs, that gender plays a role in the ability of employees to update their knowledge and skills. Despite improvements in recent years, society still expects and finds women engaged in the majority of housekeeping duties, regardless of employment status. This second shift that women have to work at home decreases the amount of time available to maintain the currency of their IT knowledge (e.g., Ahuja, 2002). A mother with childcare responsibilities may have trouble finding either the time to engage in training or the money available to pay for additional childcare duties while attending training. This expectation of women's role in society therefore places an additional burden on them to maintain the currency of their job skills. And this problem is particularly acute in IT where the life-span of necessary job skills is relatively short.

Consequently, employers need to make accommodations for women if they want them to continue to be viably employed in the IT industry. There are a couple of different strategies that employers could use that would address this problem. The first solution would involve changing the way that training is offered. Assuming that it is possible, companies could make use of distance learning/computer based training strategies. Utilizing this technology would enable working mothers to train at their own pace whenever they find the time to do so.

The next two strategies, while helpful for many women, are less likely to be implemented because both of them require additional costs that must be either borne by the employer or shifted to the employee. The first of these alternatives is to provide training during the workday. The second option would be either the provision of, or reimbursement for, childcare during the training session. While this does increase the cost of providing training, childcare may be cheaper than the lost productivity from the previous alternative. Alternatively, employers may be willing to accept the costs of childcare as the price of keeping talented women in their IT workforce.

LIMITED VERTICAL/INTERNAL JOB MOBILITY

Many women who work in IT jobs hold positions that require a relatively low-level of schooling. For these women, networking and obsolescence are not their main career concerns. The main category of job in this area falls under the general heading of data entry. Low skilled positions like data entry require very little training and preparation (Jenkins, 1999). While data entry is not the only low skilled IT job in the labor market, this discussion will focus on these workers for numerical reasons. According to recent census numbers, the majority of people in data entry jobs were women. Approximately, 80% of the 581,000 employed (US Census Bureau, 2005) data entry operators are women. The main problem facing women in these positions is largely structural in nature, as the following illustrates:

Dana has been doing data entry work for the past 10 years. In that time, Dana has worked for seven different companies, entering everything from medical records to television rebates. Among the reasons that Dana has worked for some many different employers is that, although she has not gone to college, she is quite bright and gets bored because of the repetition. Learning what different companies do is one of the few things she finds interesting about her job. While her supervisors all have liked her and have been sorry to see her leave, they haven't been able to keep Dana. Although they know she is bright, she doesn't have the skills necessary for one of the entry-level professional IT positions and the company doesn't offer that kind of training. The best these supervisors can do is to suggest that she go back to college. Unfortunately, Dana has neither the time nor the money to do so. So instead of moving up, Dana moves on to the next company.

While the data entry worker can go from one job to another, their careers remain horizontal rather vertical. They tend to move from one data entry position to another, or even in and out of IT altogether, without advancing in organizations. The reason for this is that such jobs exist in relative isolation. Structurally the jobs are not linked to others in organizations. Without prescribed paths it is difficult for managers to work with employees to create development plans that would facilitate upward mobility. Given this problem, and the low skill level necessary to perform their jobs, data-entry workers are often treated as a renewable rather than as a human resource by organizations. Over time, this problem will potentially get worse as organizations' find new ways to automate or outsource data entry. As the number of jobs decrease, women in data entry will have fewer mobility options available to them, which will dramatically increase the level of competition.

To properly address this issue, employers will need to rethink the role of data entry workers in their organization. One way to do this would be to create bridge programs to move data entry clerks into formerly entry-level, now transitional, IT job. Examples of such jobs could include testing, documentation, and help-line specialists. This changes a dead-end job into an entry-level position, and thus the organization increases the desirability of data entry positions. Consequently, this should increase the number of people who apply for new data entry positions, which then allows the organization to be more selective. Therefore, the organization may be able to increase the overall quality of its workforce.

Recruitment and selection of new data entry workers is not the only way that the organization may be able to improve the quality of its workforce. Using an internal promotion system to fill entry-level IT positions should have the effect of increasing loyalty within the workforce, as the organization now provides the opportunity for a career and not just a job. Further, the time spent as data entry workers provides management with a lot of information about who is and who is not a good worker. Consequently, the organization would only promote the best and thus will be able to lower the number of bad hires they make.

CONCLUSION

While conceivably there are many pathways for addressing the imbalance in numbers of male and female IT workers, many of these focus on the IT "pipeline." However, these strategies tend to focus on the short-term, unless supplemented with mechanisms to retain a proportionate number of female workers in the field. As discussed in this paper, entry into IT is only the first of several career challenges that women will need to effectively address.

If the number and percentage of women working in IT is to fundamentally increase for the long-term, it is incumbent on organizations to take the lead and initiate programs and policies that will help foster such an outcome. The organizational strategies provided in this paper are suggestive and are examples of how an organization can demonstrate its commitment to women in IT. These strategies are not exhaustive and each organization must determine for itself how best to promote and retain women given their resources and limitations.

KEY TERMS

General Skills: Job skills one can use in any employment situation.

Horizontal Mobility: Staying at the same organizational level when taking a new job.

Mentor: Person who provides career guidance and support to a junior colleague.

Network: One's social relations in a business context.

Portability: Ability to apply knowledge in a different context than it was developed.

Protégé: Person receiving career guidance and support from a senior colleague.

Skill Obsolescence: When job skills cease to promote productivity.

Vertical Mobility: Traditional upward promotion process within an organization.

Checking Female Foeticide in the Information Age

Chetan Sharma
Datamation Foundation Charitable Trust, India

Divya Jain
Datamation Foundation Charitable Trust, India

INTRODUCTION

In India, the practice of sex-selective abortion or female foeticide (in which an unborn baby is aborted or killed before birth simply because it is not a boy) is only the latest manifestation of a long history of gender bias, evident in the historically low and declining population ratio of women to men. Moreover, the medical fraternity in India has been quick to see entrepreneurial opportunities in catering to insatiable demands for a male child. Until recently, the technology was prohibitively expensive. The three chief pre-natal diagnostic tests being used to determine the sex of a foetus (sexing) are amniocentesis, chronic villi biopsy (CVB) and ultrasonography. Amniocentesis is meant to be used in high-risk pregnancies, in women older than 35 years. CVB is meant to diagnose inherited diseases like thalassaemia, cystic fibrosis and muscular dystrophy. Ultrasonography is the most commonly used technique. It is non-invasive and can identify up to 50% of abnormalities related to the central nervous system of the foetus. But sexing has become its preferred application. A ban on the government departments at the center and in the states, making use of pre-natal sex determination for the purpose of abortion a penal offence, led to the commercialization of the technology; private clinics providing sex determination tests through amniocentesis multiplied rapidly and widely. These tests are made available in areas that do not even have potable water, with marginal farmers willing to take loans at 25% interest to have the test. Advertisements appear blatantly encouraging people to abort their female foetuses to save the future cost of dowry. The portable ultrasound machine has allowed doctors to go from house to house in towns and villages.

Figure 1.

In a democracy, it is difficult to restrict rights to business and livelihood if the usual parameters are fulfilled. An argument by Rathee (2001) brings to light the fact that the recent technological developments in medical practice combined with a vigorous pursuit of growth of the private health sector have led to the mushrooming of a variety of sex-selective services. This has happened not only in urban areas, but deep within rural countryside, also—areas where the other dimensions of healthcare and development are yet to penetrate. Indeed, the indications are that given these lethal combinations, the phenomenon of sex-selective abortions is growing nationwide. Furthermore, these discriminatory services are being provided and projected in the name of "democratic choice" as a measure of "upliftment" of women, since they are being saved from dowry deaths, burning and other forms of torture and violence they would have undergone once they were born. This pure greed for money is also equated by a large section of doctors to "people's demand."

BACKGROUND

In an age when females have left no stones unturned in almost every field, there are people who still accord a lower status to women. "What's wrong with a girl child? In this era of gender equality, why this sexual discrimination?" In some of our Indian societies, while a childless woman is perceived as incomplete, one who has given birth to daughters is partially complete. Only the one who has produced a son enjoys a status of sorts. The problem is intimately related to the institution of dowry. "If it's a girl child, we will have to spend first on her education and then on her marriage and dowry ... It doesn't stop there. We will also have to meet some of her expenses after marriage. How I wish I get a son!" The bias against females is also related to the fact that sons are looked at as a type of insurance. Even our religions have been prejudiced against women. According to Manu (2000 BC-2000 AD), a woman has to be reborn as a man to attain moksha (redemption). A man cannot attain moksha unless he has a son to light his pyre. Also, it says a woman who gives birth to only daughters may be left in the 11th year of marriage. This obviously shows the gender bias in our male-dominated, patriarchal society.

FEMALE FOETICIDE AND LAW

There has been an inability to discuss the issue of foeticide without the larger debate on abortion, which is legally allowed and has been seen as a triumph of the women's rights movement in the country. India has allowed abortion on broad medical and social grounds since the Medical Termination of Pregnancy (MTP) Act was passed in 1971, further trivializing the issue of foeticide. The Pre-Conception and Pre-Natal Diagnostic Techniques (Prohibition of Sex Selection) Act and Rules 1994 (as amended up to 2002) (the PCPNDT Act), a result of determined action by NGOs against grossly unethical medical terminations of healthy pregnancies, mandates that sex selection by any person, by any means, before or after conception, is prohibited. But while the Act seeks to regulate and prevent misuse of pre-natal diagnostic techniques, it rightly cannot deny them, either. The PCPNDT Act allows pre-natal diagnosis only for chromosomal abnormalities, genetic metabolic disorders and congenital abnormalities. The law, however, permits ultrasound clinics, clinics for medical termination of pregnancies and assisted reproductive facilities as a routine matter and legitimate business. Then there is the legally binding Code of Medical Ethics, constituted by the Indian Parliament in the Medical Council Act (1956) that many doctors conveniently ignore. Doctors are legally bound to report medical malpractice. The PCPNDT Act mandates that any person conducting ultrasonography or any other pre-natal diagnostic technique must maintain proper records. The Act requires use of a written form, duly signed by the expectant mother, as to why she has sought diagnosis. Violations are punishable by imprisonment and a fine. The law also permits abortions for failure of contraception. It is a huge challenge for the government to detect violations of the PNDT Act, since it is a crime of collusion and by consensus.

The Ground Reality

Female foeticede is now more widespread in the country than ever before. The practice that was restricted to a few states a few years ago has now spread all over the country. Not only the poor, but even the middle classes and the rich in India are biased against the girl child and women. The provisional figures of Census1 2001, which have frightened even the Health Department, show that the Child Sex Ratio (CSR, the number of girls in the age group of 0 to 6 years per 1,000 boys of the same age group) has declined sharply from 945 females per

Table 1. CSR and OSR

	1951	1961	1971	1981	1991	2001
CSR	983	976 (-7)	964 (-12)	962 (-2)	945 (-17)	927 (-18)
OSR	946	941 (-5)	930 (-11)	934 (+4)	(927-7)	933 (+6)

Source: Census of India

1000 males in 1991 to 927 females. Furthermore, the CSR is actually worse than the national average in Himachal Pradesh, Punjab, Chandigarh, Uttaranchal, Haryana, Delhi, Rajasthan, UP, Gujarat, Maharashtra and Daman and Diu. The Overall Sex Ratio (OSR, which looks at the ratio of all females to males, not just those in the 0-6 age group) is even worse in places like Chandigarh (773:1000), Delhi (821:1000) and Punjab (874:1000). Health experts say these are some of the lowest sex ratios in the world. Here is a paradox. During the final decade of the last millennium, the CSR recorded its highest fall, dropping 18 points from 945 to 927. However, during the same decade, the OSR recorded its highest gain, rising 6 points from 927 to 933. In every census since 1951, the two ratios have gone more or less hand in hand, dropping steadily except in the late 1970s (see Table 1 below). The sudden fall in the number of girls in the youngest age group is believed to be proof of the increased incidence of sex-selective abortions or female foeticide. Most of these abortions are the result of the misuse of sex determination technologies, such as ultrasound scanning and amniocentesis.

What is a woman's role in all this? Whether in choosing her spouse, contraception methods and the first pregnancy, place of delivery and so forth, does her choice or decision really matter at all? Or is it really possible for a woman to decide about having an abortion, if she has to survive as a daughter-in-law in the family? Let's assume her husband supports the birth of a female child; even then, she will prefer to have a male child to get respect from her in-laws family, in order to save her marriage.

- Mrs. A from Jalandhar district was married in Chandigarh. Both the husband and wife are highly educated (post-graduates). The husband earns a salary of Rs.4,000 per month. At present they live in a joint family consisting of the father-in-law, mother-in-law, brother-in-law and his wife. The brother-in-law has a 13-year-old only son. All the members are highly qualified—one of the brothers-in-law and his wife are doctors and live separately. Mrs. A has one daughter. She conceived a second time after keeping a conscious spacing of three years. In the fifth month of pregnancy, she went for amniocentesis and found the foetus to be a female. She did not reveal this to her in-laws, but secretly, with her husband's consent, she underwent an abortion. The researcher was able to contact her before the event, and found Mrs. A to be depressed and pale with fear and the guilt of having conceived a daughter. Sobbing, she said that she was ashamed of having a female foetus. While her husband did not mind having a daughter again, she herself wanted to have only two children, and to earn the respect of the family, she presumed that it is important to have a son. What a dilemma!

If a woman doesn't have any say in this matter, don't you think that this forced female foeticide is an act of violence against women? So where is the cure of this disease? With law? Doctors in India believe 2 million foetuses are killed every year through abortion, simply because they are female. Although it is an illegal practice, with the increasing availability of sex determination tests, it is impossible to keep track of such cases. There is little doubt that in India the PCPNDT Act of 1994 has not been very effective. The facts revealed by the census speak for themselves. We need, rather, to attempt more broad-reaching strategies that will address the economic and cultural roots of the problem. What is required is that the available legislation for prevention of sex determination needs strict implementation, alongside the launching of programs aimed at altering attitudes, including those prevalent in the medical profession. In rural areas, as the number of marriageable women declines, men would tend to marry younger women, leading to a rise in fertility rates and thus a high rate of population growth. The abduction of girls is an associated phenomenon. It was recently reported in *The Hindustan Times* that young girls from Assam and West Bengal are kidnapped and sold into marriage in Haryana. It is only by a combination of monitoring, campaigning and effective legal implementation that the deep-seated attitudes and practices against women and girls can be eroded.

Girls and women not only face inequity and inequality, they are even denied the right to be born if their families do not wish so. In fact, many families do not wish their women folk to deliver baby daughters. Confronted with this situation, it is high time to take preventive measures against female foeticide. Both local leadership and government agencies should plan a concerted long-term program aimed at the educational and socio-economic advancement of the community—for example, by social welfare and poverty alleviation programs—to improve the economic status of women. To wean people away from the traditional practices, voluntary organizations should come forward to promote social education and awareness among the people through cultural programs, public debate and so forth. There is a need for sustained campaigning and active monitoring of the act. State governments should realize the importance and priority of the law and not merely treat it with their usual complacency. Structures for implementation of the 1994 law need to be created at the district level. Volunteers have to be actively mobilized to monitor registration and functioning of sex determination clinics at different districts. Cases have to be filed against the violators and social consciousness has to be raised against the crime. Members of society and religious leaders have a positive role in creating a morally reformed society. The long-term task is to foster a culture of goodness and human dignity that inoculates individuals and institutions against the infection of this despicable human practice.

INTERVENTIONIST ROLE OF INFORMATION AND COMMUNICATION TECHNOLOGIES

Progress of science and technology is mandatory for the progress of a nation, but what matters most is its manifestation and beneficial application. Today, information technology has changed the communication paradigm, making it no longer difficult to reach a large number of people more or less at the same time; and that, too, enables them to respond, interact as well as obtain a copy of the information within a low-cost. information and communication technologies (ICTs), apart from making people aware of this heinous crime, can also play a highly interventionist role by proactively pursuing cases against erring doctors, booking them under the law of the land as well as helping people in general change their opinion about a “girl child.” An important tool helping the government of India accomplish their cherished goal of altogether stopping female foeticide, set up by Datamation Foundation Charitable Trust, is a Web site solely dedicated to Female Foeticide (www.indiafemalefoeticide.org). This major ICT-based campaign and advocacy program is to help prevent occurrences of sex-selective tests and selective abortions of female foetuses in India. The purpose is to mobilize the population that apparently wants female foeticide, a medical system happy to supply the necessary technology, and a section of feminists arguing that female foeticide is about reproductive rights and choices.

FUTURE TRENDS

Online Attempts to Check Female Foeticide

The India Female Foeticide portal includes some distinctive features. The “Femicide” section provides some rich background information on the prevalence and practice of Female Foeticide, including reasons for the sex-selective tests. The site not only covers the regulatory aspects—PNDT Act of 1994 and the Medical Council of India’s code of conduct to crack down sex selection – but also includes a complaint-lodging process in the best tradition of e-governance. The complaint-lodging process is a very critical feature, as it protects the identity of the complainant and yet provides an effective vehicle for booking the doctor, maternity home, ultrasound clinic or radiology clinic. The complaints are retrieved into a database format at Datamation, where they are handed over to the central PNDT Cell (Ministry of Health and Family Welfare) and other respective state and district authorities for re-addressal. To date, the Foundation has received about 580 complaints, and has passed these to respective authorities. The interpretation of the law in form of demographic data is also put on the Web site. Another important platform for the Web site is the “Pledge Support” page, which highlights two features—Pledge Support and Information. Through the “pledge support” feature, one can enter information regarding the type of volunteer service the person or the organization is ready to offer, and the "information" option allows one to enter information about any ultra-sound clinics, doctors, radiologists and so forth to enable database building.

Serving as a knowledge repository on the issue is the "What's New" page. The attempt here is awareness generation and capacity building both among the community and the stakeholders. Through e-mails, to date the Foundation has succeeded in spreading awareness among 8 million people worldwide on this issue. The "Links/Resources "page contains the contact addresses of different NGOs and agencies working for the prevention of female foeticide, and gives data for state-wise, sex ratio and female foeticide and sex selection. To enable awareness generation through sound and visual media, radio and video links have also been added to the Web site. An important feature started under this initiative is the e-Newsletter, through which the Foundation disseminates news, articles, reports and other studies on a weekly basis to make the various segments (students, NGOs, medical community, educationalists, government officials, researchers) of the society aware about issues of gender inequality, female foeticide and sex-selective abortions. "Youth Voices," a newly started section on the portal, is an effort to motivate and encourage youth participation in eradicating this menace and spreading awareness among other groups. To enable communication on this issue among various segments of society, we have started a discussion forum that allows free-flow and exchange of ideas among people.

CONCLUSION

Fully understanding that an evil such as this cannot be addressed in isolation, we are also closely examining related social malaise, such as dowry, women's underemployment and exploitation in society, education standards of the girl child as well as high school dropouts among girls, early marriages and the arranged marriage system. It is our endeavor to develop sustainable development models for each of the above-listed social malaise in India so that these have an impact on improving the ratio of females in the Indian society.

KEY TERMS

Child Sex Ratio (CSR): The number of girls in the age group of 0 to 6 years per 1,000 boys of the same age group.

Dowry: Money or property brought by a woman to her husband at marriage.

Female Foeticide: Practice in which an unborn baby is aborted or killed before birth simply because it is not a boy.

Manu: The primordial father of the human race and sovereign of the earth who first instituted religious ceremonies and devised a code of laws.

Moksha: In Hinduism, liberation and bliss (nirvana) from the cycle of rebirth (samsara); also called *mukti* or *moksha.*

Overall Sex Ratio: The ratio of all females to males, not just those in the 0-6 age group.

ENDNOTE

[1] When we talk of the Indian Census, it is important to understand that our sex ratio is defined as the number of females per 1,000 men, unlike the West, where sex ratio is the complete opposite and defined as the number of males per 1,000 females.

Childhood Interest in Computers and Adult Career Choices in IT

Paul F. Cleary
Northeastern University, USA

INTRODUCTION

A considerable amount of interest in the past several years has been devoted to the characteristics and dynamics of the fast-growing information technology (IT) industry in the United States (U.S.). Particular attention has been focused on how gains from increasing computer and Internet use are distributed across society. Do all segments of society enjoy the same level of access and use of computers and the Internet, or do some segments of society benefit more from computer and Internet use than others? This question has engaged a widespread and prolonged debate surrounding the issues of fairness of IT participation and use in the U.S. By the same token, many in recent years have also focused on how *interest* in IT and computer and Internet use are distributed across society. In this article, I focus attention on gender participation in IT: Are there differences in both interest in IT as a profession, and computer and Internet use across the U.S., and do these differences persist among young people? While there is considerable evidence that gaps in Internet access and use by gender have largely disappeared (Mossberger, Tolbert, & Stansbury, 2003; Companie, 2001; Norris, 2001; Warschauer, 2003), there is a growing concern that differences in interest in the IT industry by gender are, in fact, widening.

Although evidence suggests that the societal gender gap in Internet access and use has largely disappeared, a gender gap in IT professions still exists and, in fact, is widening. Measuring the magnitude of the gap is complicated because there are varying definitions as to which occupations comprise the core IT professions. Using data from the U.S. Department of Commerce, Current Population Survey (CPS), Meares and Sargent identify four core IT occupations: computer scientists, computer engineers, systems analysts, and computer programmers (1999, pp. 3-4), while The Council of Economic Advisors identifies five core IT occupations: electrical and electronic engineers, computer systems analysts and scientists, operations and systems researchers and analysts, computer programmers, and computer operators (The Council of Economic Advisors, 2000, p. 3). Assuming that working in an IT occupation constitutes interest in the field, then if the level of participation among women in IT declines, presumably, so does their interest in the IT industry.

BACKGROUND

The statistics on changes in the participation rate of women in the IT professions are ominous. The Council of Economic Advisors reported that female participation in core IT occupations had actually been declining since 1986, when it was 42.2%. Within the core IT occupations, women were even more underrepresented within the high-paying electrical and electronic engineering occupations, comprising only 10.1% of the workforce (Council of Economic Advisors, 2000). According to the latest research in the IT workforce, *Untapped Talent: Diversity, Competition, and America's High-Tech Future*, just released by the Information Technology Association of America (ITAA), the number of women making up the U.S. IT workforce fell 18% in 8 years. Last year, women accounted for 32% of the IT workforce, down from a high of 41% in 1996, while during the same time the percentage of women in the overall workforce was virtually unchanged, at approximately 46% (ITAA, Executive Summary).

The literature shows that differences in interest, access and use of IT, and attitude toward IT (Mossberger, 2003) are generally very complex and reflect society's choices in work and leisure activities, which depend on educational, social, institutional and cultural backgrounds (Warschauer, 2003). To more fully understand the underrepresentation of women in IT professions, the dynamics of choice that lead people to these professions must be examined. Ultimately, career choices are affected by a broad range of factors that have historical, cultural, geographical and environmental dimensions.

Many argue that adult interest in IT is determined in large part by the nature and level of exposure to the discipline as a child. Therefore, examining interest in IT among children and, in particular, girls, can serve as a major predictor of future career choice in an IT field. To measure the level of interest in IT among children, the level of Internet use can serve as a proxy indicator.

Interest in IT Among Children

Understanding the relationship between gender, career choices and the world of IT should begin with an exploration of the level of interest in IT among young people. The level of interest in IT acquired at an early age, in part, determines the level of interest generated in the adult's world. The level of interest in IT among children is based on a wide array of both internal (peer, adult, home related) and external (environmental, economic, social) factors.

Earlier research indicated that among both adults and children, females were less likely to use the Internet than males (see Attewell & Battle, 1999; Baumgarten, 2003; Corporation for Public Broadcasting, 2003; DeBell, Matthew, & Chapman, 2003; Haugland, 1992; Mengel, 1995. Hoffman pointed out that women were less likely to use the Internet than men, and that age, education and gender all affect the levels of Internet use (Hoffman, 1996).

From a societal perspective, empirical evidence shows that the existence of disparities in computer and Internet use, a "digital divide," (O'Malley, , 1999, pp. 86-87) has generally been shrinking over time for certain groups, such as women, while expanding for others. According to the U.S. Department of Commerce National Telecommunications and Information Administration (NTIA), the Internet use penetration rate in society, overall, has grown from about one-fourth of all households (26.2%) in 1998 to over one-half (54.6%) in 2003 (NTIA, 2004).

More current research now suggests that computer and Internet use among girls has caught up significantly to that of boys and that gender inequality has all but disappeared. Anderson, Bikson, Law and Mitchell (1995) point out that gender access inequality had largely disappeared by 1993, while Attewell and Battle (1999, p. 4) cited the 1994 *Times Mirror* survey, which suggested that home computer use among girls is not that different than for boys.

The Internet use penetration rate for both males and females has continued to increase since data have been reported. Not only have reported Internet use rates for males and females nationwide remained similar from 1998 to 2003, the reported rates for females actually surpassed that of males in 2003. Internet use rates from any location for males and females increased from about one-third of all households in 1998 (34.3% for males, 31.4% for females) (NTIA, 1998) to more than one-half in 2003 (58.2% for males, 59.2% for females) (NTIA, 2004).

Recent Study Findings

A study conducted by Cleary, Pierce and Trauth (2005) examined the dynamics of disparities of Internet use among school age children in the U.S. The study consisted of examining demographic, socioeconomic and geographic differences in Internet use among children using data from the September 2001CPS Computer and Internet Use Supplement (Cleary et al., 2005).

Principle results show that, not surprisingly, a broad range of interrelated demographic, socioeconomic and computer resource factors were important determinants of Internet use among school-age children, regardless of gender, but among other important findings, Internet use did not differ by gender. In fact, the Internet use of girls 6-17 years of age slightly outpaced that of boys. Results show that Internet use among boys (62.2%) was slightly outpaced by that of girls (63.7%) (Cleary et al., 2005).

Demographic Factors

The underlying household factors that affect the level of Internet use and interest in IT among school-age children are both numerous and complex. The study found that five key factors had the greatest effect on Internet use among children and potentially on interest in IT: the age of the child, the race and ethnicity of the household reference person[1], the gender of the household reference person, the geographic location of the household and the ownership status of the family's residence. In terms of these factors, the largest disparities in Internet use among school-age children were found among children from Black, Hispanic and non-citizen households.

Study results show that there is currently no significant difference in Internet use among boys and girls (age 6-17) across the U.S. Internet use from any location was defined as either in-home or out-of-home use. While in-home computer and Internet use consists of one or more PCs or laptops located in the home, out-of-home use consists of use in schools, libraries or community access centers (CACs) (Cleary et al., 2005). By 2001, CPS survey results of children 6-17 years of age indicate that, regardless of gender, two out of every three children used the Internet somewhere.

This highlights an emerging pattern of use among children. Earlier survey results from 1998 indicate that although Internet use penetration rates for society overall were only about one-third (32.5%), they were equal for both boys and girls 6-17 years of age (35.6% for males, 35.3% for females, respectively) (Cleary, 2001).

On the other hand, significant differences in Internet use by school-age children were found depending on the gender of the household reference person. Survey results indicated that Internet use levels among school-age children were significantly higher in male-headed households (66.6%) than female-headed households (59.1%) (Cleary et al., 2005). Therefore, children from female-headed households reported significantly lower levels of Internet use than male-headed households, or households consisting of married couples. This indicates that perhaps female-headed households are less able than male-headed or married households to provide and maintain Internet resources, including hardware, software, online access, expertise and support for their children, regardless of gender.

Socioeconomic Factors

The results also showed that certain underlying socioeconomic factors, such as level of education, household income and marital status of the household head, are important determinants of Internet use among school-age children. These results indicate in part that lower levels of Internet use were found among children living in households with lower levels of income and education and in households where the household head was either divorced/separated (58.2%) or never married (41.5%). Not surprisingly, Internet use among children was highest among those households where the reference persons were well educated, had high incomes and were married (66.8%) (Cleary et al., 2005). These results are consistent with those from the 1998 CPS survey of computer and Internet use, which also showed that use in female-headed households (22.3%) lagged that of both married households (37.6%) and male-headed households (25.4%) (NTIA, 1999).

Socioeconomic status (SES) (Pediatrics, 2000, p. 1350) is positively associated with income, education and wealth, and therefore, with computer and Internet use in the home. This, in turn, is positively associated with level of use in the home by school-age children. SES tends to be lower for single-headed households, whether male or female, than households in which there are two adults present. Consequently, children from female-headed families, regardless of gender, are less likely to access and use the Internet than households headed by either two parents or a male, because many are unable to afford computing resources and expertise. Results show that Internet use rates among children climb dramatically with both the level of education of the household reference person and with family income. As Cleary et al. (2005) point out, a comparative advantage among children who live in such households is realized because of the effects on Internet use of increasing levels of available workplace human capital. When parental and peer support, both formal and informal, are available, children regardless of gender tend to learn the Internet more thoroughly than in households where no home computer is present and such support does not exist.

FUTURE TRENDS

Available Computing Resources and Expertise

Results showed that the most important factor influencing the level of Internet use among school-age children is the presence of computing resources and expertise available in the household. These resources include computer hardware, software, service providers and an adult in the household able to provide expertise and support to children. This factor has the single largest impact in reducing disparities in Internet use among children, and therefore is crucial in maintaining gender equity in use among children, regardless of SES. Not only is the presence of computing resources in the household a huge positive influence in computer use among children, but the availability of computing expertise and support among adults who use the Internet either at home or outside the home is great as well. Skilled adult household members bring significant amounts of experience (workplace human capital) that can be passed onto their children, regardless of gender.

The results also show that other factors affect use, but their effects are independent. Children from Black, Hispanic and non-citizen households exhibit lower levels of Internet use because they come from lower-income households that often lack at-home computing resources and adults that do not use the Internet either at home or outside the home, and therefore provide no support (Cleary et al., 2005).

These findings suggest that households with computing resources and expertise are much better able to support and encourage children to learn and use the Internet than those without such resources. In addition to the increased availability of in-home computing resources, learning assistance, expertise and support are also readily available to these children. Although the type of support and expertise (workplace human capital) that could be provided to children at home may differ by gender, it is nonetheless transferred to children in these households.

Parental coaching and peer support exert a huge influence on the nature and level of Internet use among children and are influential in impacting both the type and the frequency of use (parents from high SES households provide higher levels of involvement and support in their children's school work) (Schneider & Colman, 1993; Bianchi & Robinson, 1997; Attewell & Battle, 1999). The importance of this support and success in school cannot be understated. Attewell and Battle indicate that there is a close positive relationship between access to home computing and the academic performance of children.

Yet, in spite of the positive affects of in-home expertise, gender interactions can be more complex. Among other effects, Attewell and Battle suggested that fathers can be more enthusiastic than mothers regarding computer and Internet use, and sons are more likely than daughters to program computers. Consequently, although traditional gender roles can be an additional factor affecting computer and Internet use among children, both genders appear to benefit from parental support.

Finally, the strong influence of household computing resources and expertise on Internet use among children also suggests that if computing and Internet resources are available, then guidance and support by an adult (with either in-home or out-of-home access) will occur, regardless of gender.

Availability of School Computing Resources and Expertise

Finally, evidence suggests that the availability of school computing resources and expertise helps reduce the disparities in Internet use among school-age children. The availability of school computing resources provides critical access links to children who come from households that lack access to in-home computing resources. Furthermore, it is particularly crucial for those children living in households where parents do not have access to out-of-home computing resources, either.

A great deal of research has been conducted on the effects of education on interest in the field of IT among young people. Schools play a significant role in gender equity and have helped considerably to reduce the gender gap in Internet access and use among children. For example, Ravitch (1998) argues that schools have been among the leading institutions in creating gender equity in the past generation. When computing resources and expertise are available in school, children without in-home computing resources have a much higher probability of using the Internet and acquiring an interest in IT than when such school resources are unavailable. Also, the benefits of Internet access accrue to both girls and boys, particularly when neither gender has at-home access to the computer and the Internet.

CONCLUSION

Policies that promote interest in IT and Internet use among children from any location need to be fostered everywhere, including those groups currently without any access. If gender equity is to be maintained in society, better Internet access for all children, regardless of socioeconomic strata, is crucial. Computer and Internet access often leads to interest in IT, and interest potentially leads to future IT career choices. If a child is unable to access the Internet, regardless of gender, then there is little chance of developing an interest in computers and Internet technology, let alone mastering its potential. Only by attaining equal access will there be a chance that more children will develop an interest in IT, leading more girls, as well as boys, to future careers in IT.

Because interest in Internet use among both boys and girls is greatest where children have in-home computer access, policy initiatives that promote expanding in-home access should be fostered, since the potential impact on Internet use among children is the greatest. This potential impact to the child includes frequent access to Internet use along with the availability of computing resources and expertise, plus the advantages accruing from the support of parental experience (workplace human capital).

Where in-home access is not available, policies that improve in-school access and use need to be developed more fully. Controlled in-school Internet access locations can potentially help stimulate interest in IT among children, even if only available for short periods of time during the day.

Furthermore, policies are needed to provide funding for Internet access and use at other locations more fully. When the school day ends, access in public libraries or in CACs would provide access alternatives where schools leave off (Cleary et al., 2005). Consequently, computing resources devoted to libraries and CACs also help provide desperately needed computing resources to those unable to access computing resources anywhere else.

To spark interest in IT, technologies that enhance navigation through the Internet, such as providing broadband access to both in-home and out-of home-locations, need to be acquired. Policies offering broadband more affordably to schools, libraries and CACs would enhance Internet access, efficiency and performance, thereby improving the Internet use experience of children (Cleary et al., 2005). In this fashion, interest in IT among both boys and girls stands a better chance of succeeding.

Reducing disparities in Internet access and use among children supports a more equal distribution, and all children will benefit. A more even distribution of Internet access among children, regardless of gender, may improve the probability that girls will develop a deeper interest in IT as a career choice, and ultimately provide future leaders who will strengthen the industry.

KEY TERMS

Community Access Centers: A public place where a local community can use computers, the Internet or other new technologies. Community access centers can include libraries, schools, community centers and other public access points (NTIA, 1998).

Computing Expertise: Two measures of potential adult computing and Internet expertise: The first is a count of the number of adults (i.e., any person 18 years of age and older) in the household that used the Internet at home, and the second is a count of the number of adults in the household that used the Internet outside the home (Cleary et al., 2005).

Digital Divide: A term used to describe the discrepancy between people who have access and the resources to use new information and communication tools, such as the Internet ("the online haves"), and people who do not have the resources and access to the technology ("the have-nots") (O'Malley, 1999).

Household Computing Resources: A measure of the number of computers in the household coded as 0=no computers in the household and 1.0= one or more computers in the household (Cleary et al., 2005).

Socioeconomic Status (SES): A broad term used to describe factors about a person's lifestyle, including occupation, income and education. It consists of two aspects: one includes resources, such as education, income and wealth; and the other includes status or rank, such as social class (*Pediatrics*, 2000, June 6, 105(6), 1349-1351).

Workplace Human Capital: Human "workplace capital" is a major source of technical expertise that comes from the occupational experience of adults obtained in the workplace. It can be transferred to non-working members of the household, particularly children (Cleary et al., 2005).

ENDNOTE

[1] **Reference Person:** The first household member mentioned by the respondent, who is the owner or renter of the sample unit. For persons occupying the sample unit without payment of cash rent, the reference person is the first household member listed who is 15 years of age or older (CPS, Basic Monthly Survey, Chapter 3, CPS Demographic Data, Bureau of Labor Statistics and Bureau of the Census, p. 6).

INTRODUCTION

Numerous studies have demonstrated that alternative educational experiences, such as online learning, produce outcomes similar to face-to-face instruction provided the method and technologies used are appropriate to the instructional tasks, there is student-to-student interaction, and there is timely teacher-to-student feedback (Verduin & Clark, 1991). However, a meta-analysis of 232 comparative studies conducted by Bernard et al. (2004) concludes that while there is no average difference in achievement between distance and classroom courses, the results demonstrate wide variability. In other words, "a substantial number of DE applications provide better achievement results, are viewed more positively, and have higher retention rates than their classroom counterparts. On the other hand, a substantial number of DE applications are far worse than classroom instruction" (p. 406).

These findings suggest that appropriate instructional design and good pedagogical practices, rather than the computer mediating technology itself, is at the center of effective online education. The growing demand for online learning only increases the challenges associated with designing and delivering effective instruction. O'Donoghue, Jentz, Singh, and Molyneux (2000) note that "The diversity of demand from these client groups therefore has to be matched by a diversity of supply. ... Meeting those requirements means putting the student at the centre of the system, which in itself represents a substantial change" (Section III, para. 6). When considering such a student-centered approach to online learning, the instructor needs to become increasingly aware of the differences among students and how those differences influence the educational experience.

One area of student differences that warrants further consideration in the online classroom is gender, especially since distance education has been extensively marketed to women since early correspondence programs (Kramarae, 2003). "Distance education is ... yet another institution where gender and power differences are constructed, and to ignore the ways that gender is under construction online is to ignore many difficult experiences of real people" (p. 269). von Prümmer and Rossié (2001) go further and declare that, "If gender is not seen as relevant, the system will not be equally accessible to women and men and will offer men more chances to succeed" (p. 137).

BACKGROUND

Online Community

A recurring theme in online education literature is the importance of developing a learning community to foster effective instruction. Palloff and Pratt (1999) call for the development of academic communities in online distance classes and declare, "without the support and participation of a learning community, there is no online course" (p. 29). In a similar vein, Moller (1998) writes that "the potential of asynchronous learning can only be realized by designing experiences and environments which facilitate learning beyond the content-learner interaction. To that end, it becomes necessary to create learner support communities" (pp. 115-116). Such online learning communities provide a framework for social reinforcement and information exchange while girding the learning experience with academic, intellectual, and interpersonal support.

Garrison, Anderson, and Archer (2001) endorse this view for the virtual classroom by noting community is extremely valuable, if not essential, in the development of higher-order learning because it provides the social context in which learning occurs. Students strengthen their learning by listening and interacting with faculty and other students. Moreover, strong community promotes the creation of partnerships for study groups and collaborative learning. Wegerif (1998) reports the social dimension of online learning to be an important predictor of the success of the distance learner. He concludes that forming a sense of community is a necessary first step for collaborative learning, without which students are likely to be unwilling to take the risks involved in learning.

Computer-mediated communication (CMC) is needed that fosters cooperation and supports social order at the classroom community level. Gunawardena (1995) observes that "in computer conferences, the social interactions tend to be unusually complex because of the necessity to mediate group activity in a text based environment. Failures tend to occur at the social level far more than they do at the technical level" (p. 148). These failures can include interpersonal conflict, low participation rates, disappointing collaboration, and low learning performances in terms of quality of learning and learner satisfaction. Chester and Gwynne (1998) observe that CMC is associated with higher levels of antisocial behavior, which is the antithesis of the mutual respect that teaching aims to foster and that is required in community building. One contributing factor is the communication pattern differences among members of the community. Lack of respect, inability to listen, and a general lack of sensitivity to others in a CMC environment pose an immense risk to learning.

Fritz (1997) compared organizational peer relationships between men and women and found that while men and women had roughly the same quantity of peer relationships, the relational dynamics differed. She notes that "women's relationships in organizations, similar to what appears to be the case in nonorganizational contexts, have the potential to be stronger and, among very close friends, are characterized by greater strength" (p. 41). Conversely, Fritz found that "men find relationships functional as well, but, socialized to be more independent, they simply do not experience as much closeness in their same-sex relationships" (p. 41). Such findings are consistent with other research (e.g., Tannen, 1991) that highlights differences in communicative and relational patterns between men and women. Such differences are thus likely to have an impact on the development of an online learning community as well as individual reactions to the virtual classroom experience.

Communication Patterns

Belenky, Clinchy, Goldberger, and Tarule (1986) theorize two paths of normal development in adult learning, which result in two different communication patterns: (a) the relational, connected, or interdependent path, which reflects the majority of women (and some men); and (b) the self-sufficient, autonomous, or independent path, which is typical of the majority of men (and some women). This model suggests that many female students place emphasis on relationships and prefer to learn in an environment where cooperation is stressed over competition. The connected voice nurtures classroom community building while the independent voice does not. In particular, the professional literature suggests that most women seek to establish *intimacy* in a relationship, whereas most men seek to establish *status* in a hierarchy, measured in terms of *independence* (Tannen, 1991).

Gilligan (1982) points out that her different voice is characterized by an ethic of caring that men as well as women can espouse. Noddings (1984) elaborates this ethic of caring as "feminine in the deep classical sense—rooted in receptivity, relatedness, and responsiveness" (p. 2). For Noddings, caring is based on reciprocity—one caring and one cared-for—and recognizes "human encounter and affective response as a basic fact of human existence" (p. 4). In this framework, both parties contribute actively to this relationship of caring. Cole and McQuin (1992) identify the following traits of an ethic of care: "a predisposition to nurture, a ready capacity for emotional involvement, a need to be sensitive about relationships and how they generate different varieties of responsibility to others, and a willingness to value particularity, connection, and context" (pp. 2-3).

C

Cognitive Style

Communication patterns may also be related to patterns of thinking or cognitive style. Baxter-Magolda (1992) studied college students' ways of knowing and reasoning. She discovered patterns of thinking that are related to gender and that parallel the communication patterns identified by Belenky et al. (1986). According to Baxter-Magolda, at the absolute stage the learner sees knowledge as held by an external authority. Females at this stage tend to function as receivers, taking notes and studying, whereas males engage in interaction with the instructor. At the transitional stage females are more likely to engage in interactivity, relying on the opinions of others to help construct their own knowledge. Males, on the other hand, are more likely to use the opinions of others as material for debate. Finally, at the independent stage, females have their own interpretations but value interactivity, whereas males tend to rely on independent processing.

Research (e.g., Merriam & Caffarella, 1991) also provides evidence that females tend to be more field dependent while males tend to be more field independent. Witkin, Moore, Goodenough, and Cox (1977) developed field theory to explain differences in cognitive processing and used the term field independence to describe individuals who are individualistic, internally directed, and accept ideas through analysis. On the other hand, field dependent individuals prefer working in groups, are externally directed and more pragmatic, and accept ideas as presented. These differences suggest that females learn better in a personal, practical, hands-on learning environment where feelings and relationships are allowed to develop. Table 1 summarizes major differences in cognitive style by gender based on field theory.

Gender Differences in the Virtual Classroom

Although early CMC literature postulates that the limited social cues found online minimize gender differences (e.g., Kiesler, Siegel, & McGuire, 1984), Herring (1993) claims that online communication is less democratic than proponents tout because gender-based communication styles carry over into electronic environments. Postmes, Spears, and Lea (1998) suggest that CMC does not encourage the liberation of individuals from social influence and general social norms. Instead, individuals tend to engage in heightened stereotypical behavior, conform to group norms, commit to the group, and engage in "us vs. them" behavior given the relative impersonal online environment. Moreover, Inzlicht and Ben-Zeev (2000) report that group composition (i.e., the gender mix of a group) can also trigger stereotype-relevant thoughts and behaviors because group composition can make salient one's social identity and the stereotypes associated with that identity.

Rice and Love (1987) suggest that CMC systems can support socio-emotional communication and the communication reflects the inherent communication patterns of the users. However, text-based CMC lacks many of the interpersonal cues that can provide implicit and explicit information about how others in a group are reacting. In a study examining online communication patterns, Rovai (2001) found significant differences by gender along the lines identified by Belenky et al. (1986). He describes the voice of male messages as tending to be more confrontational, autonomous, certain, abstract, and arrogant. On the other hand, the voice of female messages tends to be more empathetic,

Table 1. Gender-related cognitive style differences

Most Females, Some Males	Most Males, Some Females
Field dependent	Field independent
More likely to use inductive reasoning	More likely to use deductive reasoning
More pragmatic and applied	More abstract and theoretical
Learns best by watching and thinking	Learns best while doing and either thinking or feeling
More organized	More undirected
Connectedness through intimacy and physical proximity	Connectedness through social competition

mention self, family, or spouse, or had a cooperative tone. He concludes that online instructors should be sensitive to the different communication patterns used by their students and should adapt their teaching in ways that facilitate the interaction of diverse groups and accommodate individual and group differences without sacrificing or silencing other members of the learning community.

FUTURE TRENDS

Distance education has become a growth industry as the result of advances in technology and the educational needs of a modern workforce. Carnevale (2005) reports the results of a 2004 study that shows about 937,000 students were enrolled in fully online education programs at the end of 2004. By 2006, more than 1.2 million students are expected to be taking online courses, representing about 7% of the 17-million students enrolled at degree-granting institutions. Distance learners are typically older than traditional students, with the average age over 25 years old, and they are more likely to be female (Ashby, 2002).

Future research should address how best to improve online interactions in order to ensure gender equity. In particular, research is required to better understand how gender-related factors influence the learning environment, educational effectiveness, and student satisfaction. If online instructors are to design and teach using an inclusive student-centered pedagogy, they require detailed information about student differences and how those differences influence learning. For example, in a study of a blended online learning environment, Ausburn (2004) found that females were significantly more desirous of a course which provided an anchor or home base and fostered a sense of belonging and involvement than their male classmates. What other such design factors are differentially preferred by gender?

More importantly, do such differences affect the efficacy of the educational experience or merely the students' enjoyment of the course? Would students enrolled in a course whose design is contrary to their stated preferences learn less or merely find the experience more difficult? In a study of 109 online learners, Anderson and Haddad (2005) found that women reported deeper perceived learning online than in face-to-face courses, largely due to increased comfort expressing their views in class and believing that those views were valued. "Our research suggests that, for females, this greater perceived learning occurs because of the role that voice plays in strengthening perceived deep learning in both online and face-to-face courses" (Section 5, para. 1). They also found that the professor was influential in establishing this confidence and sense of voice among online learners.

The next round of research into gender-related differences in the virtual classroom needs to go beyond stylistic and preference measures to consider cognitive learning. What models of instruction work well for which students and how can instructors develop online learning environments that are equally effective for students from different backgrounds? Such studies will advance the field and help ensure that online learning meets the goals of increased access, learning effectiveness, and student satisfaction (Moore & Kearsley, 2005).

CONCLUSION

The present research-based findings suggest that females and males differ on at least two dimensions that can affect sense of community and arguably learning and learner satisfaction in the virtual classroom. The first dimension is communication pattern (e.g., Belenky et al., 1986; Gilligan, 1982; Noddings, 1984). Females generally communicate using a connected voice that emphasizes socialization, caring, cooperation, consensus, and the indirect resolution of conflict. Males on the other hand, tend to have a more independent voice that emphasizes self-sufficiency, autonomy, and competition. Such communication patterns may be influenced by cognitive style, the second dimension. Research (e.g., Merriam & Caffarella, 1991; Witkin et al., 1977) provides evidence that field dependent individuals, who tend to be females, are socially oriented, externally directed, and more pragmatic. In contrast, males tend to be field independent. A person who perceives items as more or less separate from the surrounding field leans toward a field independent cognitive style. They tend to be individualistic, internally directed, and competitive.

Additional research (e.g., Postmes, Spears, & Lea, 1998) suggests that learners tend to engage in heightened stereotypical behavior in the relatively less personal environment of CMC and online learning. Such behavior left unchecked could give rise to interpersonal conflict resulting in negative feelings, including intimidation, distrust, anger, which eventually can result in a communication breakdown, loss of a community spirit, and decreased learning and learner satisfaction. It is therefore incumbent for the online instructor to be skilled in planning and moderating online discussions.

KEY TERMS

Asynchronous Learning: Learning in which interaction between individuals occurs with a time delay, allowing participants to receive and respond to communication at a time of their choosing.

Cognitive Style: Consistencies in information processing that develop in concert with underlying personality trends (Merriam & Caffarella, 1991).

Computer-Mediated Communication (CMC): Communication, either verbal or text based, between individuals via networked computers.

Distance Education: Planned learning that normally occurs in a different place from teaching, requiring special course design and instruction techniques, communication through various technologies, and special organizational and administrative arrangements (Moore & Kearsley, 2005).

Sense of Community: Feelings of connectedness, belonging, and trust among a group of individuals and a shared faith that their needs will be met through their commitment to be together.

Virtual Classroom: A location in cyberspace where members of a classroom community meet and interact either synchronously or asynchronously in order to engage in teaching and learning activities.

Virtual Community: A social aggregation that exists in cyberspace when a group of individuals come together, interact, and form personal relationships with each other.

Comparing Gender Differences in Computer Science and Management Information Systems Majors

Sylvia Beyer
University of Wisconsin – Parkside, USA

INTRODUCTION

Why do so few women major in computer science (CS) or management information systems (MIS)? Are the reasons for women's underrepresentation in these two disciplines the same? I will address these issues by reporting on my research on female and male undergraduates majoring in CS or MIS. I hypothesize that results from one area of information technology (IT), such as CS, do not necessarily generalize to other areas of IT, such as MIS.

Structural barriers exist that keep women from advancement in IT careers (cf. Ahuja, 2002). However, an examination of these is beyond the scope of this article, which focuses on gender differences in IT students. In 2002 only 27.6% of U.S. Bachelor's degrees in CS and 36.8% in MIS were conferred on women (U.S. Department of Education, 2002), limiting the number of women qualified to enter into the IT workforce. The problem of women's under representation in IT is not limited to the U.S. Women are underrepresented in CS majors in other Western countries such as Canada (Gadalla, 2001), Germany (Huber, Reiff, Ben, & Schinzel, 2001), Norway (Berg, Gansmo, Hestflatt, Lie, Nordli, & Sorenson, 2002), and Ireland (MacKeogh, 2003).

IT cannot afford to underutilize such a valuable and significant part of the workforce. Increasing the representation of women is imperative because "greater diversity among those who create computing technology ensures that those technologies are relevant to and usable by a wider range of people" (Roberts, 2003).

BACKGROUND

Both CS and MIS are areas within IT. CS is the more mathematically rigorous and technical major and typically has requirements of advanced physics and mathematics courses. The CS major emphasizes the design, implementation, and management of complex information systems. The MIS major has a more applied focus and concentrates on the collection, processing, and distribution of data for use in decision making in business. The underrepresentation of women is greater in CS than in MIS.

Research on women in IT often implicitly assumes that results gathered in one area of IT will generalize to other areas within IT. This article explicitly tests this assumption. Given the inherent differences in the fields of CS and MIS, students majoring in CS and MIS might differ from one another. These differences, coupled with the different academic atmospheres encountered in highly technical vs. business-oriented fields might present different challenges for women majoring in CS vs. MIS.

Previous research delineated several reasons for the small number of women in CS: Low computer self-efficacy, lack of programming and hands-on computer experience, negative stereotypes regarding the field, and lack of role models. Women have inaccurately low self-evaluations (i.e., their confidence is lower than warranted by their abilities) in domains traditionally considered masculine, including mathematics and chemistry (Beyer, 1999a, 2002), and CS (Beyer, 1999a; Beyer, DeKeuster, Walter, Colar, & Holcomb, 2005; Beyer, Rynes, Perrault, Hay, & Haller, 2003; Lips, 2004). Although women extensively use computers as tools, they have less programming experience than men (Beyer, DeKeuster, Rynes, & DeHeer, 2004; Beyer, Rynes, & Haller, 2004; Margolis & Fisher, 2001).

CS is stereotyped as very male-dominated and both men and women *incorrectly* believe that male CS majors have higher grade point averages (GPAs) than female CS majors (Beyer, 1999b). The stereotypes about individuals in computer-related fields are unflattering: CS majors are perceived as intelligent but interpersonally deficient (American Association of University Women, 2000; Beyer, Rynes, & Haller, 2004). This has been termed the "computer nerd syndrome", "geek mythology", or "hacker mentality" (Jepson & Perl, 2002; Margolis & Fisher, 2001). CS is also incorrectly perceived as involving only programming and no creativity (Craig, Fisher, Scollary, & Singh, 1998). The perceived obsession with machines and lack of interest in people, and associations of technology with masculinity conflict with women's interpersonal orientation, that is, their tendency to value careers with opportunities for social interaction and nurturance (Cross & Madson, 1997; Zahn-Waxler, 2000). This may deter women from majoring in CS. Unfortunately, we know little about the stereotypes about MIS students.

We have at least a rudimentary understanding of what deters women from taking CS classes (see also Lagesen, 2003; Margolis & Fisher, 2001). Departmental and classroom climates in CS affect the success of students (Margolis & Fisher, 2001). Social support, faculty encouragement, and the presence of role models are more important to women's than men's decision to enroll in or leave CS (Cuny, Aspray, Cohoon, & Jesse, 2003; Margolis & Fisher, 2001). Indeed, "female students in technical disciplines, perhaps partly because of their 'outsiderness,' are especially vulnerable to poor teaching, inhospitable teaching environments (such as large classes), and unhelpful faculty" (Margolis & Fisher, 2001, p. 83). For example, female engineering students with low self-evaluations who perceived the academic environment in their department to be supportive, experienced lower levels of stress and higher self-esteem one year later than women who perceived the department as less supportive (Cross, 2001). Again, we know little about MIS students.

METHOD

All participants were enrolled at the University of Wisconsin-Parkside, a public university with an undergraduate enrollment of approximately 5000 students. In the CS sample, 108 students participated (25 females, 83 males); in the MIS sample, 135 students participated (67 females, 68 males). To make comparisons between the two IT majors possible, I assessed constructs that were found to be important in previous research on CS and extended them to MIS. I measured students' computer experience and self-efficacy; stereotypes about CS or MIS; role models; and climate in the classroom and program. Furthermore, I collected students' ACT scores (an achievement test commonly administered in U.S. high schools) and college grades. More details on the measures and statistical tests can be found in various publications (Beyer & DeKeuster, in press; Beyer, DeKeuster, Rynes, & DeHeer, 2004; Beyer, Rynes, & Haller, 2004; Beyer et al., 2003, 2005).

RESULTS AND DISCUSSION

Table 1 presents the means of the variables discussed. Throughout I will point out similarities and differences in the results of the CS and MIS samples. To assess gender differences, analyses of variance, chi-squares, and regressions were calculated. All reported gender differences are statistically significant at the $p < .05$ level or better.

Mathematical Ability, Computer Experience, and Self-Efficacy

CS students had higher mathematics ACT scores than MIS students underscoring their greater mathematics aptitude. No gender differences were found in mathematical aptitude (ACT scores) or grades in students' major for CS or MIS students. Other researchers have also found no gender differences in the grades or standardized test scores of students in mathematics-intensive majors (Cross, 2001). Male CS and MIS students had more programming experience and more experience installing RAM in a computer than did their female counterparts.

To determine whether there was a gender difference in computer self-efficacy when controlling for mathematical ability, I regressed participants' computer self-efficacy on gender, mathematics ACT score, and the interaction. As can be seen in Figure 1, female CS majors had lower computer self-efficacy than male majors regardless of their ACT scores. The same was true for MIS majors. Thus, female CS and MIS majors' computer self-efficacy

C

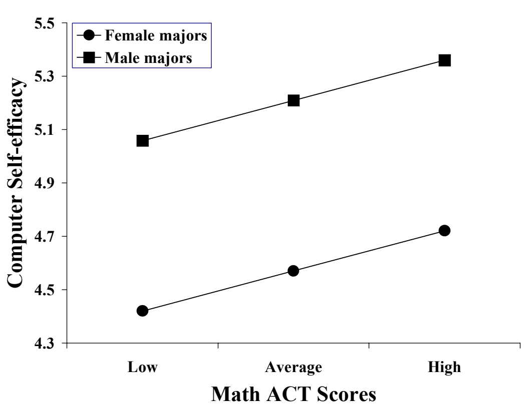
*Table 1. Means of variables discussed in text. * Scale ranges from 15 to 36; ** Scale ranges from 0 to 4; *** Scale ranges from 1 to 7*

	CS Majors		MIS majors	
Dependent Variables	Females	Males	Females	Males
Mathematics ACT scores*	25.3	23.9	21.9	21.3
GPA in CS/MIS classes**	2.8	2.8	3.2	3
Hours per week computer used for enjoyment	6.1	10.9	4.6	10.1
Installed RAM	50	82	32	74
Programming experience	81	94	77	93
Estimated weekly work hours of CS/MIS professionals	47.5	44.9	47.4	49.4
Age when first became interested in CS/MIS	20.8	15.8	N/A	N/A
Sex of computer teachers in high school***	4.4	4	4.8	3.4
Knew someone in CS/MIS	65	52	38	40
CS/MIS faculty are sensitive to students' needs***	4.7	4.9	5.2	4.4
The CS/MIS program atmosphere is impersonal ***	3.4	3.4	2.7	3.5
The CS/MIS faculty expect too much of students***	3.8	3.6	2.9	3.5
CS/MIS courses are too limited for my career goal	3.3	3	3.4	4.2
Faculty don't take female CS/MIS majors seriously ***	2.6	1.6	2.3	1.8
Ability of female CS/MIS majors is underrated ***	3.7	2.9	3.4	2.2

was lower than males', even when quantitative ability was statistically controlled. In fact, female CS majors with high mathematics ACT scores felt less self-efficacious than did male CS majors with low mathematics ACT scores.

Other researchers have found a similar gender difference in self-efficacy in undergraduates in mathematics-intensive majors (Cassidy & Eachus, 2002) and engineering graduate students (Cross, 2001). In fact, girls have lower computer self-efficacy than boys as early as fifth grade (Dickhäuser & Stiensmeier-Pelster, 2003). Computer self-efficacy is affected by the amount of previous experience with computers (Cassidy & Eachus, 2002). Indeed, female students in our study had less programming experience and less hands-on technical experience than male students did.

Figure 1. CS students' computer self-efficacy



Stereotypes about CS and MIS

There were few gender differences in stereotypes about CS or MIS. However, stereotypes of CS and MIS majors as "nerds" and their perceived lack of interest in people conflict more with women's greater interpersonal orientation (Cross & Madson, 1997), probably deterring women from majoring in CS or MIS.

Role Models

Female MIS majors had more female computer teachers in high school than male MIS majors did, a difference not found for CS students. These female computer teachers in high school may have served as role models for women, nurturing their interest in a computer-related field. A study of female engineering students in Germany also found that secondary school teachers had encouraged these young women (Blättel-Mink, 2002). Furthermore, a case study of female CS students in Germany found that positive experiences with computer teachers in secondary school cemented their interest in CS (Huber et al., 2001). However, in our sample of CS students, female students were not significantly more likely to indicate that their computer teachers in high school had been female.

Climate in the Classroom and Program

To set the following findings in perspective, at our institution the CS department's seven faculty includes three women; all of the four MIS faculty members are male. Despite having only male MIS faculty, female MIS majors had less negative perceptions of the climate in MIS classrooms and the program in general than did male MIS majors. For example, male compared to female MIS majors felt that the climate in the MIS program was more impersonal, that MIS faculty are less sensitive to the needs of MIS students, and that MIS faculty expect too much of MIS students. No gender differences for these variables were found for CS students.

Although on an absolute level students felt there was little discrimination against women, significant gender differences did emerge. For example, female compared to male CS and MIS majors felt that faculty in CS/MIS do not take female majors as seriously as male majors and that faculty underrate the ability of female CS and MIS majors.

Thus, for general questions about the climate in the CS/MIS programs and classrooms, no gender differences were found for CS majors and the gender differences for MIS majors were in the direction of greater male dissatisfaction. However, consistent gender differences in CS and MIS were found regarding students' perceptions of subtle forms of gender discrimination. Both female CS and MIS majors perceived there to be more gender discrimination than did their male counterparts, which may contribute to attrition among female CS and MIS students.

FUTURE TRENDS

Beyond the specific findings of this research, an important contribution of this study to the literature on women in IT is that it points out that generalizations from research on women in one IT area, such as CS, to a different area in IT, like MIS, are not always appropriate. Several findings did differ by IT discipline. Women majoring in CS are different in their aptitude, interest, and a host of psychological variables and face different challenges in their academic departments than women majoring in MIS. Thus, generalizations from research findings on women in CS to women in MIS or vice versa are inappropriate and may lead to erroneous conclusions. Future research on the underrepresentation of women in IT should carefully examine the differences in the various IT fields. To this end, comparable assessments of students in a greater variety of IT fields would prove valuable. Furthermore, it would be instructive to assess non-IT fields as a comparison group. This would yield valuable insights regarding the generality of findings where gender differences are consistent within IT fields. For example, in this study female CS and MIS majors perceived more gender discrimination than did males. Is this finding specific to IT, does it hold for all male-dominated majors, or possibly all majors?

CONCLUSION

Prior to offering conclusions, I point out limitations of this research. The relatively small number of female CS majors limits statistical power. This means that some real gender differences may not have been detected in our sample. In addition, the data were gathered at a small public university, possibly limiting generalizability to institutions of similar size.

This research examined a large number of variables that could adversely affect the number of women majoring in CS or MIS. Variables that might negatively impact women in CS or MIS include less programming experience, lower computer self-efficacy, fewer available role models, and subtle forms of gender discrimination in the classroom. Our findings suggest possible avenues for increasing the representation of women in CS and MIS.

Women in the CS and MIS samples had lower computer self-efficacy than their male counterparts, which may decrease the likelihood that they will choose to major in CS or MIS and may increase the likelihood that female CS or MIS majors will drop out of their major. This means that women miss the opportunity to enter into highly paid fields with

C

excellent career potential. Therefore it is important that instructors help increase female CS and MIS students' computer self-efficacy. Encouragement and steering female students to activities that increase their practical skills such as internships or teaching or lab assistantships may accomplish this.

One potential explanation of women's lower computer self-efficacy is a lack of experience in programming. To increase the number of women in computer-related fields exposing them to computers may not be enough. Programming might be a crucial experience for all students interested in computer-related fields, but might be particularly important for women's computer self-efficacy. Because CS is the more technical field, female CS majors' lower computer self-efficacy is likely to have more serious repercussions than it does for female MIS majors.

Role models are important in getting women interested in MIS. Female MIS students had more female computer teachers in secondary education than did male students.

There were no gender differences in CS majors' perceptions of the general classroom climate and their program, whereas male MIS majors had consistently more negative perceptions than their female counterparts. In light of the fact that women's attitudes toward their classroom experiences and their program were either not different from men's or in fact more positive, it is especially interesting that women reported more subtle gender discrimination than their male counterparts perceived. To increase retention departments should carefully avoid creating any perception of gender discrimination. Departments that address self-efficacy and gender discrimination issues that are of concern to female students may be rewarded with increased retention and recruitment of female students.

KEY TERMS

Computer Self-Efficacy: Refers to a person's confidence in his or her computer skills. Women have lower computer self-efficacy than men.

Inaccurate Self-Evaluations: Refer to a comparison between an individual's ability and his or her perception of ability in a specific area. Women's self-evaluations are inaccurately low for stereotypically masculine domains, such as CS.

Interpersonal Orientation: Refers to a person's orientation towards people as opposed to objects. Women score higher than men on interpersonal orientation. In their career aspirations they emphasize professions that allow them to help others, to nurture, and/or to have frequent social interactions with co-workers or clients. CS is typically perceived as a field that appeals to individuals who are low in interpersonal orientation.

Perceived Gender Discrimination: Refers to students' perceptions that their instructors display differential behaviors or attitudes toward female and male students.

Role Model: Is an individual who serves as a source of inspiration. Role models show others who are similar to them in demographic characteristics such as sex or race, or are similar in goals, abilities, aspirations, or personality that success in a certain area is possible. Role models may not be aware that they are performing this function and may not even know the individual(s) they are inspiring.

Stereotypes: Are individuals' beliefs about social groups. Stereotypes need not be negative, nor are they always inaccurate.

Stereotypes about CS: Include the "nerd" "geek" or "hacker" images of computer scientists. Computer scientists and CS students are often stereotyped as intelligent, particularly regarding quantitative skills, but single-minded in their interests, and interpersonally deficient.

A Complex View of Technological Change in the UK

Anoush Simon
University of Wales Aberystwyth, UK

INTRODUCTION

This article seeks to discuss women's ambivalent but potentially positive attitude to and relationship with new technologies, as exemplified by Internet and mobile technologies, using as an illustration the results of a UK-based qualitative study into women's perceptions of technological change. The research sought to investigate how individuals understand recent technological developments, analysing the data in the light of theoretical discussions of new technologies and the information society, as well as feminist analyses of gender and technology.

The spread of information and communication technologies has been rapid and significant. For instance, the number of UK households that are connected to the Internet has increased steeply from 9% in 1998 to 52% in 2004, while also in 2004, 37% of UK adults had not yet used the Internet. Meanwhile, individual ownership of cellular phones has increased swiftly to over 70% (Office for National Statistics, 2004). This implies a considerable range of experience and inexperience of new technologies amongst the general public currently. Government policy has also impacted the diffusion of ICT in the United Kingdom, as elsewhere. In particular, the development of the People's Network of Internet access points in public libraries throughout the United Kingdom has been a prominent strand in the government's information policy (Library and Information Commission [LIC], 1997), aiming to make new technologies widely available to the citizenry and requiring people working in this field to become Internet literate, with implications for library staff at all levels of employment. Indications are that the People's Network may be altering the library-user demographic, and that many people are experiencing the Internet for the first time via the public library ("Beardy-Weirdies' Rule," 2003).

These developments led to an interest in perceptions of technological change, particularly among those working in the library sector, as a site of government information policy. The focus of the research was women working in this field, but it was complemented by a further sample of women with little or no experience of new technologies. The intention behind this was to provide a rich variety of data whilst maintaining a focus on individuals who are less often the subject of research on new technologies. The study took an interpretive perspective, utilising in-depth, semistructured interviews with 50 women as described above during the period of 2001 to 2002, and using grounded theory to analyse the resulting data. This approach favours the development of concepts that are rooted in the data, useful for an exploratory project, which can be subsequently compared to and placed in the context of existing literature and theory. An overview of the central theoretical contexts of the project is presented below followed by a discussion of the results and their wider relevance.

BACKGROUND

Women have long been dominant in the library field, accounting for upwards of 70% of the employees in the UK and U.S. library sectors (Harris, 1999), and they have been the focus of some research in this respect, particularly in the field of information studies, from which this project originates. Underrepresented at the higher end of the salary scale, their dominance at the lower or nonprofessional end is marked. It has been argued that the predominance of women in a profession may negatively impact its status (Harris, 1992). In fact, gender relations are becoming increasingly important in the library sphere, as this traditionally "female-intensive" profession becomes a "technologically dense site," and as yet, insufficient attention has been paid to this issue (Dilevko & Harris, 1997, p. 719). Technological change may de-skill women or downgrade their traditional roles in the library sphere, although Harris also points out an often-positive attitude to such change in the workplace (1992, 1999). Of course, women have been using technology in libraries long before the advent of the Internet, and are understood to have been "intensive systems users" throughout the 1980s (Green, Owen, & Pain, 1993, p. 132). A more recent development, however, as noted above, is the way that government policy, in the United Kingdom at least, seeks to engage library workers at all levels with new technologies.

The broad framework for the research was the concept of the information society and discussions of social and technological change within this context. There is an ever-growing body of work on the information or network society, for example, Castells' (2000) key study of the information age. Within the field of information studies, literature focuses on the role of the information worker or information policy in the United Kingdom, as well as wider analyses of technological change (Dearnley & Feather, 2001; Feather, 2002). Some authors take a critical perspective toward the concept of the information society itself or the hyperbole that seems to attach to it, and to the technological developments that are understood to underpin it (Garnham, 2000; Golding, 2000; Robins & Webster, 1999; Webster, 2002).

Clearly, then, there are many examples of theoretical analyses of the information society and new ICT. In recent years, there has also been a welcome increase in the number of empirical studies that investigate the role, use, and place of the new technologies such as the Internet in everyday life, helping us to ground our understanding more firmly in the context of individuals' lived experience (Wellman & Haythornthwaite, 2002; Woolgar, 2002). It is this developing understanding to which it is hoped the current article contributes.

An important perspective also comes from feminist analyses of women and technology, particularly gender and technology studies that theorise the social construction and gendering of technologies (Adam, 1998; Cockburn, 1994; Faulkner, 2001; Grint & Gill, 1995; Kirkup, 1992; Wajcman, 2000). In terms of empirical research, much literature attests to the differences in experience of and attitudes toward computers between men and women, although many studies also acknowledge other cultural factors involved. It has been argued that as the Internet becomes pervasive, women's attitudes to it become increasingly important. It is less and less a matter of "take it or leave it" as it becomes harder to avoid engaging with ICT, therefore it becomes ever more vital to understand how women think about and deal with technology in their everyday lives (Li, Kirkup, & Hodgson, 2001).

EXPERIENCE AND PERCEPTIONS OF ICT

Many of the women interviewed for this project expressed very positive attitudes toward new technologies, or at least some aspect of them (the Internet, cell phones), which may be understood as an encouraging sign for women's future relationship with ICT and the information society. This was especially evident among library staff that had some regular access to the Internet at work. However, it was by no means a universal or consistent expression, and many sceptical or critical points of view were also articulated. Most commonly evident was a sense of ambivalence toward new technologies and their apparent social implications. It is helpful to think in terms of a shifting continuum of attitudes, ranging from the dismissive and highly sceptical to the positive and enthusiastic. Most points of view existed somewhere between these points and were flexibly dependent upon the type of technology being discussed, its location, and mode of use. Ambivalence is articulated in particular ways in the women's talk, as described below. The concept is examined here in terms of how it is apparent in the data and how seemingly contradictory attitudes are reconciled, or at least enabled to coexist, as individual women make sense of and integrate social and technological change into their everyday lives.

Many women, particularly those who regularly used new technologies such as the Internet, reported positive or empowering experiences. This ranged from simply overcoming their doubt and suspicion of a new technology, to being regular, enthusiastic users, making use of various ICT in many aspects of their lives. Participants often described feelings of reluctance or scepticism before having their first contact with ICT: Subsequently, they felt much more positive or at least comfortable with new technologies. Enjoyable and confidence-building experiences were often described, allowing women to help both themselves and others. Many women had a story about learning something new, making or renewing a contact, accessing information for themselves, which made them feel more in control, or successfully making a purchase online for the first time.

From this perspective, it is possible to envisage the Internet as a site for women's leisure and pleasure without resorting to perhaps more unfounded "cyberfeminist" proclamations about the liberating nature of new technologies (critiqued by Adam, 1997). It can be understood, rather, in terms of an ambivalent but pragmatic approach to new technologies that is grounded in individuals' everyday experience.

For many of those interviewed, their knowledge of the Internet had been gained or developed in a work context; for example, those women who worked in the library profession had, or were currently undergoing, various forms of ICT training. The location of ICT use, for instance, the workplace, appeared to be a factor in how at ease the women felt with it. In the library work environment, women may be able to experience a level of access to ICT that might not be available to them within the domestic sphere. Because an emphasis has been placed on their professional development, now including computer proficiency, being a skilled Internet user is a key part of the information worker's portfolio of skills: According to one participant, "You have this barrier—we've had to overcome it at work, but at home you don't have to unless you want to."

Of course many people have Internet access at home, but as some commentators have noted, we have as yet very little information about how computers are placed in the domestic sphere and how their use is negotiated. The home, for women, is traditionally not a clear-cut site for leisure, which may be interrupted or fragmented by various household tasks (Green, 2001). Indeed, some women explicitly stated that they used the Internet, including for personal use, at work rather than at home for a variety of reasons: being able to find the time, a better connection speed, and not having their children and/or spouse (usually the former) taking up time on or having responsibility for the computer.

QUESTIONING THE VALUE OF NEW TECHNOLOGIES

Doubtful or ambiguous attitudes were also clearly evident, and ambivalence emerges as a dominant theme. Some women would clearly state their uncertainty: "The Internet's a funny thing, I kind of feel. I kind of feel it's great and I also kind of feel it's quite dangerous."

In other cases, ambivalence would become apparent in the course of the discussion. For instance, some women expressed a fear of being left behind if they did not keep up with new technologies. This was compounded by the perception that certain factors served to exclude those individuals that did not or could not access the Internet, for example. Reference was made, for instance, to the assumptions that appeared to be made in schools that a child had access to the Internet outside the classroom (e.g., in setting homework), or to the way in which the established media seem to assume connection, and how they emphasise a lack of access by constant reference to Web sites, for example, in advertisements or at the end of television programmes. This may serve to construct individuals as outside the network age and also creates the feeling of imperativeness to be online.

On the whole, negative or doubtful attitudes came from those who had less, or no, actual experience of ICT, although it is more complex than simply thinking in terms of a user-nonuser binary. Some nonusers expressed simple disinterest in ICT (which may of course mask a deeper anxiety), while more experienced users resisted certain aspects of new technologies or used the rhetoric of resistance or scepticism when discussing them. Although it is articulated in varying ways, such ambivalence appears to range across levels of experience and educational background. It may be expressed in terms of different attitudes toward difference aspects of ICT, different attitudes toward the same technology depending on context, or different opinions at various points within a dialogue. Rather than assessing this as a contradiction, we can instead understand it as part of a process of making sense of change, which is revealed in these conflicting yet coexisting perceptions. This was manifest in tensions that appeared within a dialogue, and also in self-conscious discussion of positive and negative aspects of ICT. What were deemed to be appropriate and inappropriate uses of specific technologies were also highlighted.

To provide an example, mobile (cellular) phones were often a topic of discussion in this respect. This aspect of new technologies attracted very strong feelings. The tensions apparent here were between an understanding of mobile phones as useful or even indispensable, and many expressions of annoyance or exasperation at what was deemed unnecessary or thoughtless use, for example, loud conversations on public transport, people using them while driving, or an audience member taking a call during a school play. Others talked about peer pressure or selling their soul as part of the process of acquiring a mobile phone while also acknowledging their dependence on it. There appears to be a fast level of adjustment to change, with participants being highly conscious of their change in attitude. Similar observations were made in relation to the Internet:

... I think it's ... merged into the background as it were. It's not mentioned per se, it's not mentioned as "ooh you can now do this, and you can now do that," you know. It's just accepted I think ... part of everyday life.

The comparison of new technologies with other earlier technological innovations was a tool often employed to articulate the process of technological evolution and to describe personal adaptation to change:

All these things, we when first got a video [VCR]—we all started off, obviously, in families where we didn't have any of those things. You start off thinking you don't need it, then you get one and you find 'oh yeah, it is quite useful' ... It's been exactly the same with each new thing.

It has been argued that ambivalence toward ICT (in Western societies at least) may promote a process of appropriation in order to "de-alienate" and familiarise particular technologies (Lupton & Noble, 2002, p. 20). Other methods of de-alienation may apply too, such as comparing new technologies to established ones (the telephone, television, radio) and locating them in this context in terms of other societal changes.

FUTURE TRENDS

There appears to be rapid adaptation to change and an integration of new technologies into women's everyday lives. As such, it is argued here that ambivalent or contradictory attitudes are integrated, or made sense of, by individuals seeing ICT both as positive and negative rather than either-or. This is a very fluid position: Women are finding their place in the information age, accepting parts of it, and rejecting or regarding with suspicion others.

Henfridsson (2000) discusses the diverse interpretations that attach to a new and unknown technology in the workplace, but which solidify over time and use into more consistent meanings. We might think along these lines in a wider social sense: The implications of new technologies are as yet unclear, and not only to those actively involved in researching the field. The scope for interpretive ambivalence is thus wide, perhaps more so amongst those with limited experience, and allows for a variety of sense-making processes. Many positive experiences and perceptions were highlighted in the research, but this was tempered by more critical attitudes, often within the course of a single dialogue. These appear to coexist rather than cancel each other out, and may find support in understandings of ambivalence as a more realistic representation of women's experience of technology (Faulkner, 2001) and, as such, a more practical way forward in analyses of gender and technology.

Due to the rapidly developing nature of new technologies and the various stages of this expansion in different cultures, this study inevitably represents a case study or snapshot of the situation in the United Kingdom. Longitudinal methodologies would seem to lend themselves to studies of perceptions and acceptance of technology, and it is intended that the author will pursue such an approach in order to develop the concepts outlined here.

CONCLUSION

It is evident that women enjoy new technologies and gain confidence from using them, however, their interest or need to be online should not be assumed. What is important is to understand the agency of the individual, and the variety of women's interpretations that are grounded in both gender and experience of technologies, but also in the social complexity that is the context of their lives.

This is not to say that ambivalence does not reflect genuine issues of concern, for example, the fact that the low numbers of women entering the computing and IT industries remains problematic, and that this takes place within the context of social constructions of technology and gender that may impact what technology is available to them, where it is available, and how their roles in relation to it are defined. But the agency of those interviewed, in terms of attitudes and understandings as well as action, is also apparent. The participants of this research are thinking critically about technological and social change, and this is reflected in the complexity and variety inherent in the interview data.

C

KEY TERMS

Information Policy: An umbrella term referring to government policy in relation to information, ICT, or the development of the information society.

Information Professional: A qualified person (usually with a degree) working in the field of librarianship or information management, including libraries, information centres, and records offices.

Information Society: A widely debated concept that foregrounds information and especially ICT in the developing social structure.

Information Studies: A broad academic discipline covering all aspects of the library and information profession—both the practical and theoretical.

Information Worker: Libraries employ both professional and nonqualified staff, although the boundaries between them in terms of roles and status are often blurred.

People's Network: A network of Internet connections in public libraries across the United Kingdom established with government funding (1997-2002).

Computer Skills, Technostress, and Gender in Higher Education

Sonya S. Gaither Shepherd
Georgia Southern University, USA

INTRODUCTION

The creation of computer software and hardware, telecommunications, databases, and the Internet has affected society as a whole, and particularly higher education by giving people new productivity options and changing the way they work (Hulbert, 1998). In the so-called "information age" the increasing use of technology has become the driving force in the way people work, learn, and play (Drake, 2000). As this force evolves, the people using technology change also (Nelson, 1990).

Adapting to technology is not simple. Some people tend to embrace change while others resist change (Wolski & Jackson, 1999). Before making a decision on whether to embrace technology or not, people may look at the practical and social consequences of accepting change. Therefore, the technology acceptance model, the accepting or resisting of technology is considered to be a form of reasoned behavior (Wolski & Jackson, 1999).

BACKGROUND

Technology changes the way people work and learn. As the role of technology is being defined and technology is constantly being improved, change is inevitable (Brand, 2000; Davis-Millis, 1998). As a result, those involved in higher education have to find ways to adapt to technological change. Administrators, faculty, academic librarians, and students should define the role of technology for the purposes of (1) sharing new ideas and techniques for teaching and learning; (2) encouraging enthusiasm and innovativeness; and (3) learning about opportunities and challenges, and how to deal with them (Landsberger, 2001).

In fact, college faculty are spending more time with those from the business sector to ensure what is taught in the classroom is applicable in the workforce (Gavert, 1983; Katz, 1999; Lynton, 1984). This partnership is providing opportunities for faculty to remain current in rapidly changing technical disciplines because both are collaborating on curriculum that meet education standards and job related skills required in industry (Gavert, 1983; Katz, 1999). And the researcher presumes that professors in Colleges of Business Administration are more adept and comfortable using technology than those in other colleges within universities. On the other hand, other disciplines such as liberal arts have had less need to adapt as quickly, and perhaps have been more reluctant to change (Miller & Rojewski, 1992).

Likewise, education faculty are preparing future teachers, counselors, and administrators to go into elementary, middle, and secondary schools. These teacher programs may or may not require their students to obtain and use technological skills. Similarly, there may or may not be an expectation among the education faculty to obtain or utilize these same skills. Some education faculty and students may only learn and use technology because they wanted to and not because there was an expectation (Miller & Rojewski, 1992).

University library staff also has had to adapt to a wide variety of technological demands unimaginable just a few years ago (e.g., processing library materials and teaching research skills online). Other disciplines such as liberal arts have had less need to adapt as quickly, and perhaps have been more reluctant to change. All, however, are faced with the necessity to change. Therefore, in all likelihood, all faculty and librarians are experiencing some level of technological stress.

Furthermore, the rapid growth in technology over the last three decades has been well documented. Accompanying that growth has been an equally rapid increase in the struggle to keep up with technology. The way services are provided by society and to society (e.g., fast, instantly, remotely) is changing. While virtually all facets of society are affected by technology, its impact can be clearly seen in the way higher education clientele have been served. Colleges and universities are being changed in multiple and profound ways, ways almost unrecognizable to students, faculty, academic librarians, administrators, and alumni.

The move to the Information Age, with its changes and need for adaptation to technology, has been rapid and stressful for many people. While many people have increased their technology use and are comfortable with it, many others still do not use much technology and are not comfortable using it when they must do so. For those who are not amenable to change, who find it difficult to adapt, there are often a variety of responses or results. One such response is called technostress. Technostress is the inability to adapt to or cope with new computer technologies which reveals itself in one of two ways: (1) computer users struggle to accept the technologies or (2) computer users over-identify with the technology (Brod, 1984).

Studies relating to technostress have been fairly limited. Those conducted have sought to determine correlations between such variables as personality type, academic performance, self-concept, and why certain faculty decided to use technology while others do not. Study participants have included people from the business industry, students majoring in business and education, and a limited number of faculty members and librarians. However, there are few studies that look at the severity of stress for various types of computer users (e.g., faculty, academic librarians) in postsecondary settings based on the computer users' gender.

For example, differences between females and males regardless of discipline were identified in the way they accepted or resisted technology. Even though Sievert, Albritton, Roper, and Clayton (1988) and Ballance and Ballance (1992, 1993) found computer-related stress was not related to computer experience and sex, other researchers found a relationship. For instance, females experienced technostress or resisted information technology (IT) more than males (Fine, 1979; Elder, Gardner, & Ruth, 1987; Hudiburg, Brown, & Jones, 1993; Ogan & Chung, 2003). Additionally, Heinssen, Glass, & Knight (1987) believed the less computer experience a female had the more computer anxiety she experienced. Murphy, Coover, and Owen (1989) revealed men were better able to perform certain computer skills more successfully than females. Similarly, Reed and Overbaugh (1993) found men to have less computer anxiety as their computer experience increased. According to Baroudi and Levine (1997), "women were generally more scared of computers ..." (p. 178). Finally, females rated information technology as the fourth cause of stress while men rated IT as the fifth cause of stress (Sax, Alexander, Korn, & Gilmartin, 1999).

Male and female faculty members and librarians also identified the IT they used as well as certain coping skills to help them handle the increased stress. The information technology identified included e-mail, spreadsheets, the Internet, statistical software, presentation software, and multimedia software (Groves & Zemel, 2000) where e-mail, spreadsheets, and the Internet were highly used. They suggested eating, relaxing, staying healthy, having a positive attitude, managing time, setting realistic goals, and seeking additional training as ways to cope with their stress as they continued to use information technology (Hickey, 1992; Kupersmith, 1992; McKenzie, Davidson, Bennett, & Clay, 1997).

With this, the intent of the current study was to explore the relationship between technology skills and the possible causes of technostress among academic librarians, and education and business faculty. The exploration looked at the role, if any, of how gender may have also made a difference in this relationship between technology skills and technostress.

FUTURE TRENDS

Research Method

This study was originally designed to answer the following question based on several demographics: Do computer skills relate to the levels of technostress among faculty in the Colleges of Business and Education, and academic librarians? However, the main focus of this article is on the gender of faculty in the Colleges of Business and Education, and academic librarians and the relationship between their computer skills and levels of technostress. As a result, 994 eligible participants were identified and 316 usable surveys were returned (32.8% return rate).

Participants were given the option of completing a survey instrument electronically and having the responses e-mailed to the researcher (n=234), or receiving numbered, color-coded paper copies, and mailing the results back to the researcher in a self-addressed stamped envelope (n=93). The numbered, color-coded paper copies were used to keep track of participants who responded so the researcher could do follow-up requests for survey participation. The survey was a new instrument containing four sections: (1) Computer Hassle Scale-revised (CHS-R); (Hudiburg, 1999) (2) Computer Skills Survey (May, 1998); (3) two open-ended questions; and (4) demographic items. When completing the CHS-R section of the instrument, respondents were asked to circle the number corresponding to the severity of the computer hassle they have experienced. Choice of numbers were 0=not at all, 1=rarely severe, 2=moderately severely, and 3=extremely severe. They were asked to complete the Computer Skills section by rating his/her skill level. Answer choices were 1=low, 2, 3=medium, 4, and 5=high. The faculty and academic librarians were then asked to answer two open-ended questions about what they perceived to be possible causes of technostress and possible solutions for relieving technostress. Lastly, faculty and academic librarians were asked to provide certain demographics including gender.

Alternatively, participants completed the instrument electronically by filling out a Web-based form posted on the Internet. Using the same numeric code found on the paper copy of the survey, each faculty member or academic librarian wishing to complete the instrument online was able to enter that code on the Web form for tracking purposes. The code was used to keep track of those who responded to the survey so the researcher could request participation from non-respondents after follow-up contact had been made with those not responding initially. Each participant completed the CHS-R section by clicking the radio button corresponding to the appropriate severity level of each of the computer hassles they have experienced. The choices were the same as the ones on the paper copy. Similarly, the Computer Skills section had clickable radio buttons corresponding to the skill level for each computer skill. The choices were the same as those on the paper copy. Two open text boxes were provided for respondents to type in their responses to the open-ended questions. Lastly, clickable radio buttons were provided for responding to the demographics section. All responses from the survey were snail mailed or e-mailed to the researcher for data analysis.

Research Findings

The major findings of the current study were:

1. Male and female business faculty reported their computer skills as the highest over education faculty and academic librarians (see Table 1).
2. Male and female academic librarians perceived themselves to experience more severe levels of technostress than male and female business and education faculty (see Table 1).
3. Male academic librarians reported the lowest computer skills level, while female academic librarians perceived to experience higher levels of technostress (see Table 1).
4. All males reported lower computer skill levels and they perceived to experience more severe levels of technostress (see Table 2).
5. The levels of technostress among males and females regardless of discipline decreased as their levels of computer skills increased (see Table 2).
6. Academic librarians, education and business faculty regardless of gender used a wide va-

Table 4. Technostress causes as perceived by COBA, COE faculty, and academic librarians

Cause	Frequency
computer information problems • difficulty keeping up, too many passwords	178
computer runtime problems • hardware failure, computer crashes	119
computers' impact on society • increase in expectation to use computers, increase in demand or time to use computers	70
Internet/E-mail problems • too much e-mail, spam	48
everyday computer technology • confusing, threatening computer terminology, answer cannot be found	42
computer processing speed • slow CPU/Internet connection	41
computer as person • lack of human interaction	8
computer costs • software costs	2

Note: Hudiburg (1997) identified eight categories for measuring causes of technostress

riety of software applications or other computer technology but they mainly used e-mail, word processing, and the Internet (see Table 3).

7. Participants identified computer information and computer runtime problems more than any other problem as causes of their technostress (see Table 4).
8. Solutions for reducing technostress as reported by the participants included calling for help, screaming or yelling, walking away, leisurely talking to someone, and doing something non-technical or non-computer related (see Table 5).

Findings-Past and Present

According to Fine (1979), Elder, Gardner, and Ruth (1987), Hudiburg and Jones (1993), Heinssen, Glass, and Knight (1987), and Ogan and Chung (2000), females experienced more technostress and resisted technology more than males which contradicts the findings of this study. However, the current study's results supported those revealed in Reed and Overbaugh's (1993) study that men had less computer anxiety as their computer experience increased. Additionally, faculty and librarians identified word

Table 5. Coping solutions as perceived by COBA, COE faculty, and academic librarians

Solution	Frequency
increase knowledge and skills • ask for help, attend training workshops	114
relax or socialize • take nap, talk to people	77
manage time or projects/tasks • multi-task, back up data	77
complain • threaten computer, yell and curse	54
try to fix the problem • reboot computer, start project over	29
exercise • yoga, play basketball	24
change attitude/expectations • find humor in situation, control anger	24
eat • drink tea, eat popcorn/candy	12
perform non-technology related tasks • clean office	1

processing, spreadsheets, and e-mail as highly used information technology (Groves & Zemel, 2000) while e-mail, word processing, and the Internet were identified in the current study. In summary, further research may be needed to understand how gender may relate to computer users' technostress levels and their computer skills. Furthermore, researchers could investigate the roles males and females play in the decision making process of technology implementation and training, the increased expectation to use technology in classrooms, and the increased expectation to use technology for tenure and promotion.

CONCLUSION

This study attempted to investigate whether computer skills relate to the levels of technostress among male and female faculty members in the Colleges of Business and Education, and academic librarians. The analysis of the data revealed a negative relationship that as computer skills increased, technostress levels decreased among males and females. However, further study may be necessary to determine and understand more the relationship of computer skills and technostress among males and females. Moreover, in order for computer users to experience less stress, they will have to keep up with the rapid change of technology and take part in some form of training on a regular basis. "Changes break patterns that we are comfortable to, and that can be rather threatening. The key is to make sure that we are the masters, and that computer and other formats of technology are tools we manipulate. IN SHORT, WE ARE THE ONES WHO ARE IN CHARGE!" (Rocha, 2001).

KEY TERMS

Academic Librarian (LIB): Person who has completed an outlined course of study from an accredited library school and performs one or more of the following: (1) purchase and catalog resources for public use; (2) help find information for search or study; (3) plan, operate, and maintain computer systems; and (4) manage and plan library operations; and may or may not hold faculty status.

Business Faculty (COBA): Professor/instructor who teaches business courses at a college or university.

Computer Technology (aka Technology or Information Technology): Machines with cd-rom, DVD, zip, and/or floppy disk drives with software applications which are used to enhance human efficiency and workflow.

Education Faculty (COE): Professor/instructor who teach education courses at a college or university.

Information Age: Creation of computer software and hardware, telecommunications, databases, and the Internet.

Information Problems (aka Computer Information Problems): Having little or no information or sometimes having too much information when trying to utilize computer technology.

Over-Identification with Technology: Constant use of technology or over reliance on a computer to complete a task especially if the task is simple and may be performed by an individual much faster than performing the task by computer.

Post-Secondary Settings: Any college or university that prepares a person for a career beyond high school at the undergraduate and/or graduate level.

Runtime Problems: Difficulties occurring while software applications are being used.

Technostress: Modern disease of adaptation caused by an inability to cope with computer technologies in a healthy manner and manifests itself in one of two ways: (1) struggle to accept computer technology and (2) over identification with computer technology.

INTRODUCTION

Governments and international organisations have expressed concern regarding what has been labeled the digital divide, that is, the gap between those people who have access to, and the ability to use, modern information technologies—such as computers, the Internet, e-mail, and other mobile technologies, often referred to as information communication technologies (ICTs)—and those who do not. As a result a range of measures have been put in place by public agencies in an attempt to reduce the inequities between the "haves" and the "have nots". One strategy which has commonly been used is the establishment of free and easy access to computing and Internet facilities within communities identified as needing such assistance.

In Wellington, New Zealand, a project called Smart Newtown has been implemented whereby free public access to computers and the Internet and free introductory classes are made available to all citizens. The researchers were employed to evaluate the implementation and sustainability of this project and this chapter discusses how, over a period of three years, the participation of women has changed. The questions asked were "How did the women benefit from their attendance?" and "What caused this change in participation?"

The article begins with a brief background on gender and ICTs, followed by a short review of the literature regarding the digital divide and community computing. One of the successful computing centers in the Smart Newtown project is then examined from a gender viewpoint.

BACKGROUND

While the term ICT does not exclusively refer to the Internet and its applications, but to other modern technologies, applications and services used to organize, transform, and transmit information (Marcelle, 2000), the Internet remains the main focus. From its inception, the Internet has been dominated by male "geeks", but when the World Wide Web became accessible to the general public, much was made of its potential to reshape and reorganize our work and "enhance the quality of human life" (Huyer & Sikoska, 2003, p. 1). It soon became clear that gender inequalities of access to, and understanding of, the Internet and its potential benefits continued, and Spender (1995) in her seminal book "Nattering on the Net: Women, power, and cyberspace" highlighted some of the specific inequalities which were becoming evident.

The first phase of the World Summit on the Information Society held in Geneva in 2003 raised gender-equality awareness by insisting on the critical relevance of gender to ICTs. This was timely as the adoption of ICTs has become internationally widespread amongst both developed and developing countries and it is of concern that many women are still not participating in the emerging information society (UNDP/UNIFEM, 2004). This is despite the programs that have been put in place by many governments, the United Nations, and international organizations to encourage adoption and use of ICTs as a means of helping reduce poverty and promote sustainable human development.

In New Zealand, groups identified as being likely to be excluded from the digital society include Maori and Pacific peoples, those on low incomes, solo parents (usually women), people with no or low qualifications or poor literacy, the unemployed, people with disabilities and people living in rural areas that lack a sound telecommunications structure (Community Employment Group, 2002). The consequences of exclusion from the digital era is noted in a recent report (The Economist, 2005, p. 11) where "the real digital divide" is defined as "but a symptom of deeper, more important divides: of income, development and literacy."

THE DIGITAL DIVIDE

Early definitions for the term digital divide, believed to be a "simplifying metaphor" by van Dijk and Hacker (2003, p. 322), refer to the gap that exists between those who have and those who do not have access to these modern technologies. The focus was initially on access and adoption rates to the technologies by different sectors of society within the developed world. DiMaggio, Hargittai, Neuman, and Robinson (2001) described the digital divide as being the inequality in access to the Internet including the degree to which it is used, knowledge of how to extract and evaluate information, and the variety of uses to which it is put. Others define it more broadly as the difference between those people who do or do not have access to technologies such as telephone, television, or Internet (Gurstein, 2003).

Gender, race, and class are factors, highlighted in many studies, where inequity of access exists. Often women have less money than men and this can prevent them purchasing the equipment necessary to gain access and training (Wylie, 1995). Two of the most critical issues regarding the 'gender digital divide' relate to access and control, and education, training and skill development (UNDP/UNIFEM, 2004) and it is in these areas where community ICT initiatives can play a pivotal role.

COMMUNITY COMPUTING

Community ICT projects with the objectives of increasing social capital and reducing the digital divide are recognized as being complex and often fail to meet these goals. Warschauer (2002) believes ICTs must have a social inclusion focus. He suggests a model that involves access to physical artifacts (computers and telecommunications), relevant content, human resources and skills, and social support in the form of community, institutional and societal structures that help access to ICTs. Warschauer considers these four sets of resources have an iterative relation with ICT use. The combining of all four sets of resources contributes to successful and efficient use of ICTs and, once effectively used, feed into promotion and extension of the resources.

Pinkett and O'Bryant (2003) take an "asset-based" view to community development and recommend leveraging the resources within a community by "mapping" these assets and then "mobilizing" them to "facilitate productive and meaningful connections" (p. 192). Asset-based community development uses existing resources (assets) within the community (thus being internally focused) and encourages the ongoing establishment of productive relationships among community members. Users are empowered through technology supporting their interests and become active producers, not consumers where the emphasis is on outcomes instead of access.

The approaches to community ICT taken by Warschauer (2002) and Pinkett and O'Bryant (2003) are underpinned by the principle that ICTs should be useful, effective, meaningful, and relevant. These theorists agree the end result should be user-focused.

The usefulness and relevance of ICTs is especially important for women in the early adoption stages of ICTs. Females need to perceive computers as a "tool to use within a broader context" (Fisher, Margolis, & Miller 1997, p. 4). The provision of a non-threatening, culturally suitable environment where women are able to learn how to use the technologies, with encouraging assistance is therefore vital. The next section presents an example of how a community ICT initiative has increased the participation of women and contributed to social capital through education, training, and skill development.

THE PROJECT

New Zealand has been a rapid adopter of new technologies. However, it was not until 2002 that the government committed itself to its first strategy to support community access to ICTs in an effort to close the digital divide (Community Employment Group, 2002). This strategy has given rise to a number of initiatives that are often supported by local or regional government, along with business and community organizations. One of these initiatives is the Smart Newtown Project, established in Newtown, an inner-city suburb of New Zealand's capital city, Wellington. The broad goals of the project are to assist disadvantaged groups to develop ICT skills essential for daily life, strengthen intra-family relationships, extend social networks, widen education and employment opportunities, and improve their future contribution to the economy. This section describes the Pacific Island Network Centre (PINC) and how the community ICT initiative has helped women, particularly immigrant women, achieve these goals.

The suburb of Newtown was selected because of its low socio-economic community. For at least five decades a significant proportion of its population have been new immigrants; initially Pacific Islanders, Indians, and Chinese. More recently, the immigrant community has diversified but has largely been comprised of people from war zones such as Somalia and Iraq, many of whom are refugees. When immigrants arrive from such countries they are faced with significant barriers including language acquisition, cultural differences, economic problems and, for those women who are unable to work, isolation due to lack of access to social networks and separation from their families. There is also a large population of solo parents, unemployed and other socially underprivileged groups in Newtown.

Eleven networked computers were installed at PINC in 2002. Members of the public have free access to the computers and the Internet and free classes are available in basic applications such as word processing, spreadsheets, Internet searching and e-mail. These classes are offered in modules covering introductory, beginner and intermediate grades and consist of two two-hour sessions per week over four weeks. The computing coordinator, an immigrant from India, is responsible for teaching the classes, maintaining the computers, and coordinating volunteers. The center is open weekdays from 10 am-5 pm.

PINC has many of the precursors for success as a community computing centre—it is a non-threatening, community owned and operated public space (see Liff & Steward, 2001). It has also successfully leveraged off existing resources and augmented them with technology to create a successful new community resource—a necessary criteria for success identified by Pinkett and O'Bryant (2003). In the three years since the computers were installed there has been a noticeable increase in the number of females using the center and enrolling in the classes.

Results

Computer user statistics regarding casual usage and enrolment in classes have been gathered over the three-year period. As well, formal interviews and casual conversations with a variety of stakeholders have been conducted and regular observations of the room undertaken by the researchers. The qualitative data support the user statistics.

In the first year the majority of participants, both casual users and those enrolled in the classes, were Indian males. Many of these users reported that their reasons for coming to the centre were to access the Internet to look for work or to gain skills which would lead to better work opportunities. By 2004, 25 different ethnicities were using the centre, and from June 2003 until the end of 2004, female participation in classes consistently outnumbered those for males. In fact, for five of 10 months in 2004, there were at least 50% more females than males, a significant percentage being new immigrants. There was also an increase in husbands and wives attending classes together, thus reinforcing intra-family relationships.

Another interesting change has been that women are now consistently using the Internet and email more than men. In one case, an Iraqi woman brought her mother to classes so she could learn to use the Internet and email in order to access the Iraqi news and have contact with family members residing in other countries. Another was able to receive digital photographs of her baby nephew, print them, and take them home to her family. This ability to communicate with family, and maintain timely links with their home country, was very important to the immigrant women.

A further important aspect was the forging of friendships through attendance at classes. PINC provides a supportive and welcoming environment for users, with a very helpful coordinator and volunteers on hand. This is especially encouraging for those who are lacking in confidence or unsettled and homesick, as many immigrants and refugees may be. The PINC computing environment has many of the characteristics of a "third place" (Oldenburg, 1991). It is a welcoming, comfortable, socially inclusive setting where people can come and go at will, has frequency of regulars and good accessibility and visibility. Users encourage, support, and help each other—a collaborative approach to learning that appeals to many women.

PINC also provides a number of software programs that facilitate ICT adoption such as the Equal Skills package which is an animated computer familiarization course that also provides an introduction to the Internet. Learning is facilitated by a skilled tutor guiding the onscreen instruction. The blended learning environment is of special importance because many of the participants are from developing countries and have very limited English ability (Crump, 2004).

The immigrants who come to PINC to learn English have recently enjoyed the opportunity of having their language instruction combined with learning computer skills. Students are introduced to the Internet and shown how to access and use English language sites as well as how to access sites from their home countries. This has the additional benefit of helping new immigrants feel less isolated and can assist their adjustment to the new country. Of the 17 students in the first intake of this combined class, 12 were women. Again, this illustrates the value of a blended learning environment.

The success of the participants' new ICT skills' acquisition is celebrated on a regular basis. There is a communal morning tea where people contribute a plate of food and a prize giving at which certificates of achievement are awarded for completion of the computing modules.

These examples illustrate how the PINC computing center has developed a repertoire of relevant programmes in a supportive environment which not only empower women with new skills in ICTs but provide an inclusive, safe environment that combines ICT and English language education as well as the opportunity for expanding social networks.

FUTURE TRENDS

In the future, as ICTs become ubiquitous and the digital divide narrows, it is likely that the purpose and appearance of community ICT centers will change. They may look very different because of advances in types, size, and capability of computer hardware and software. However, while there remains concern for impoverished communities, characterized by disconnectedness with each other as described by Robert Putnam (2000), the community centers will have a role in meeting social needs that could remain centered on ICTs.

CONCLUSION

This urban study demonstrates the success of using ICTs with an underserved group of people within a third place environment. The feeling of belonging, attachment, and sense of cohesion by members of this community has developed over time. Initiation into ICTs within a socially inclusive environment and using the computers for useful, relevant purposes has contributed to the successful and changed ICT adoption rate amongst female, particularly immigrant, participants.

KEY TERMS

Blended Learning: The combining of technology with traditional, face-to-face human assistance.

Community Computing: Provision of technology access within a community context. This may be as simple as hiring the use of a mobile phone to villagers for a few minutes to establishing a physical computing centre within a geographic or virtual community.

Digital Divide: The disparity or distance between those who can and those who cannot access and use ICTs.

ICTs: A broad term that includes technology which has some form of computer and communication capability. These may be mobile phones, radio, television, computers and the different services and applications related to them.

Social Capital: The creation of value and specific benefits that flow from a connected community. These include trust, reciprocity, information, and cooperation associated with social networks.

Third Place: A term coined by Oldenburg (1991) to describe an informal, public place on neutral ground that promotes social equality through people gathering and interacting. Third Place contrasts with first place (home) and second place (work).

Underserved Communities: Communities that lack access to ICTs due to geography, economic conditions, ethnic background, or disability.

Constructing Gender Bias in Computer Science

Tarja Tiainen
University of Tampere, Finland

INTRODUCTION

Gender bias in technical fields, as in computer science (CS), is a well-known phenomenon. It is shown in presenting computing history as a male victory, while female computing pioneers have been forgotten (Gürer, 1995; Vehviläinen, 1999). The statistics demonstrate gender bias in IT (information technology) workplaces nowadays: only about 20 to 30% of computer professionals are women, and they also have lower salaries than men working in IT (Ahuja, 2002; Pateli, Stack, Atkinson, & Ramsay, 1999). Furthermore, there are studies dealing with CS students (e.g., von Hellens, Nielsen, & Beekhuyzen, 2004). Few studies focus on CS academics. Camp (1997) is one of the rare ones: She describes the shrinking pipeline problem in the USA. Women hold 25% of master's degrees in CS, but only 6% of full professors are women. (Camp, 1997) The CS field is not the only one where female professors are rare. Husu (2001) presents two reasons the general bias is causing: (1) like professionalism in general, academic professionalism is also connected to masculinity and (2) female post-graduate students and newly qualified doctors get less support from their senior colleagues than their male counterparts. Besides supporting to complete studies successfully, older colleagues can support post-graduate students in becoming members of the academic society, which is essential in making an academic career.

This article concerns on the construction of the gender bias among CS academics. I will focus on what happens in everyday practice and how gender bias is reproduced over and over again. I see gender as a process which is constantly under negotiation. In this article, the negotiation process is studied by analysing one case, which is one university department in the technical field. This article focuses on the negotiation of gender within the department; it does not deal with what happens in society or in families (such as taking care of children), although they both affect women's working situation in a department.

The structure of this article is as follows. First, the theoretical background of the relationship between masculinity and technology is described, as it forms the basis for understanding the gender bias in the CS field. Second, the empirical case is described. Third, the suggested explanations for the gender bias are dealt with and connected to the theoretical understanding of gender and technology. Fourth, a forecast of future trends is given, and, finally, conclusions are drawn on the main points of the article.

UNDERSTANDING THE BACKGROUND OF GENDER BIAS

When we try to understand gender bias in the CS field, it is useful to start with thought-models which, according to Wajcman (1991, pp. 137-144), include a connection between masculinity and technology. The connection is not inherent in biological sex difference, but rather a result of the historical and cultural construction of gender (Wajcman, 1991). Although the connection between masculinity and technology is commonly accepted, the views of the mechanism vary. I will present them using the classification of Gill and Grint (1995).

One response to the perceived link between masculinity and technology has come from *eco-feminists*. It sees women as being essentially close to nature because of being rooted in biology. Women's biology, the theory argues, has led to a specific way of "knowing" and experiencing the world which is undervalued. The aim is to retreat into female culture and produce "woman-friendly," feminine technologies. (Gill & Grint, 1995, pp. 5-6.) This perspective is used in practice in creating women's own ICT groups (see, e.g., Vehviläinen, 2000).

For eco-feminists, technology is inherently and inevitably patriarchal, but for *liberal feminists*, technology is neutral. For them, the issue is the different ways in which men and women are posited in relation to technology. (Gill & Grint, 1995, pp. 6-8.) It is important to involve more women in technical fields and to increase their participation in technical education. As technology is seen as neutral, women have to change their attitudes to take the opportunity; it is seen as a question of women's individual choice (Vehviläinen, 2000).

Powerful criticism of both the liberal and the eco-feminist positions has made way for a new approach: seeing *technology as masculine culture* (Gill & Grint, 1995, p. 8). This approach views technology as being much more than simply artefacts or hardware; it is also knowledge and practices involved in the use of technology (based on Grint & Woolgar, 1997). Seeing technology as masculine culture implies that the link between technology and masculinity is reproduced in everyday practices. (Gill & Grint, 1995, pp. 8-12.) According to this approach, gender is not natural or stable, but socially constructed (Wajcman, 1991). Masculinity and femininity are used as abstract frames of reference; a kind of standard that one refers to in the articulation of one's own gender as well as of that of others. Thus, speaking of a connection between masculinity and technology does not mean that technology reflects the capacities of specific men, rather the qualities of some social image of masculinity. (Lie, 1995; Wajcman, 1991, p. 143)

THE CASE OF CSUT

I will describe how the connection between masculinity and technology manifests itself in workplace practice by citing a case, which is the department of CSs in the University of Tampere (CSUT), Finland. Finland is a five-million-inhabitant country in Northern Europe. It is typically presented as a gender equal country, which is evidenced in women's and men's equal proportions of the labour force and in women's and men's equal levels of education: 26% of Finnish women and 22% of men hold academic degrees; women have 51% of the master's degrees and men 49%, but the situation is reversed among PhDs, as 66% of the degree holders are men and 34% women (StatFin, 2004). The discussion of gender equality ignores the fact that the Finnish labour market is strongly segregated into women's and men's work (Kolehmainen, 1999).

The case in this study, CSUT, has about 500 students and almost 100 faculty members. There are 25 teaching posts, ten administrative, and supportive posts, and the rest of the staff are temporary project researchers, whose contracts are typically made for one year at a time. CS is understood as a wide field including five streams: algorithmic, software development, information management, information systems (IS), and interactive technology.

I will focus on the teaching staff, because their posts are thought to be permanent and they are selected with a view to the benefit of the whole department. The teaching staff in CSUT includes ten professors (one of them is an emeritus professor), six instructors and nine senior academic assistants (see Table 1). The professors and instructors have permanent posts, but someone may occupy a post on a temporary basis, typically for a year. Nowadays there are also semi-permanent professorial posts which are for three to five years. Senior academic assistantships are typically postdoctoral posts, in which half of the working time is used for research. They are temporary posts, the standard duration of which is five years (called here semi-permanent), but they may be for one year (called temporary). The teaching staff includes five women and twenty men (see Table 1).

In Finland, it is normal for doctors to continue to work in the same departments where they wrote their dissertations. This is also the case in CSUT: 11 of the 25 male PhDs and three of the eight female PhDs were working in CSUT at the end of 2004. The

Table 1. The number of teaching staff in CSUT at the end of 2004

	Permanent		Semi-Permanent		Temporary		TOTAL	
SEX	M	F	M	F	M	F	M	F
Professor	7	0	0	1	1	1	**8**	**2**
Instructor	2	1	-	-	2	1	**4**	**2**
Senior assistant	-	-	2	0	6	1	**8**	**1**
TOTAL	**9**	**1**	**2**	**1**	**9**	**3**	**20**	**5**
Percent	**90**	**10**	**67**	**33**	**75**	**25**	**80**	**20**

Note: M=male; F=female

Table 2. Number of PhDs in CSUT and the number of posts they hold in CSUT at the end of 2004

	Male		Female	
	PhDs	**Posts**	**PhDs**	**Posts**
1970s	2	1	0	0
1980s	2	2	1	0
1990s	5	2	1	0
2000s	16	6	6	3
Total	**25**	**11**	**8**	**3**

statistics relating to the decade, starting from the first PhD degree at CSUT in the 1970s, are presented in Table 2. In the table, "posts" refers to the number of decades during which PhDs had been working in CSUT by the end of 2004.

Gender bias in CSUT is seen in two points. The first is education. In Finland, women and men hold master's degrees to the same extent, but in the case of PhDs, there is a gender difference. This is also the case in CSUT, where only eight of the 25 (32%) PhDs were taken by women. Besides the smaller number of female PhDs, the female PhDs do not obtain posts in CSUT as often as male PhDs: only 20% of the posts are held by women (Table 1), although the percentage of female PhDs is higher. Furthermore, if we focus on those PhDs who do not work at CSUT, there is also some gender difference. All female PhDs work at universities, but five male PhDs work in industry and three male PhDs at other institutions (not universities); so five female and six male PhDs work in other universities.

SUGGESTED EXPLANATIONS FOR THE GENDER BIAS

In the Finnish universities, the aim is to reach gender equality, which means, for example, that there are an equal number of men and women in every post category. The University of Tampere, like all the Finnish universities, has a plan for increasing equality. CSUT is one of the problematic departments as the gender bias is worse in CSUT than it is in the university as a whole. When the issue is under discussion, two kinds of explanations are suggested by the Head of CSUT and by all the male CSUT professors. The first explanation is that there are no qualified women. The second one is that if there have been some sufficiently qualified women, they have chosen to leave CSUT. I will deal with both explanations and connect them to the above theoretical approaches to gender and technology. After that, I will present some other related issues which have an effect on the construction of such a biased situation.

First, I will deal with the explanation that it is women's own choice not to work in CSUT. Eight women have done a PhD in CSUT. Six of them worked in CSUT during their post-graduate studies but only two continued to work in CSUT immediately after obtaining a PhD. Moreover, no woman from outside CSUT has obtained a post. The male professors in CSUT see this as women's own choice. They talk in the same way as Vehviläinen (2000) claims liberal feminists do: if there are no legal obstacles, the absence of women is a question of women's individual choice. Following this approach, it is relevant to ask women to change their attitudes, not to ask what is wrong with CSUT as women do not want to work there.

The other explanation for women's absence focuses on the alleged lack of qualified women. Eight women have taken their PhDs in CSUT. However, the dissertations of four of the women relate to IS studies, whereas the mainstream in the teaching in CSUT is connected with computer-centred areas (algorithmic, software development and information management). Most often, there is a need for another kind of qualifications than experts in IS have, and, therefore, the four female PhDs are not qualified for those posts. However, the focus of CSUT is not an objective truth emerging from the mass, but is defined and determined by the present professors of CSUT. The focus of CSUT is negotiated among seven permanent male professors. They also decide the focus of new posts; their area, their permanency, the qualifications required, for example. When the male professors decide on the future focus of CSUT, their own subjective views colour the negotiations. They renew their status and power in CSUT, ignoring new, non-represented areas.

In the previous paragraphs, I presented an explanation that follows the views of liberal feminism in assuming that the gender bias is women's own choice. Continuing to the other explanation, we got some evidence which follows the idea of the eco-feminist approach: women have different knowledge than men—or women's science is different from men's science. In CSUT, we can find that some of the female PhDs had gone to new areas which were outside the earlier focus of CSUT, such as the study of gender and technology, as two female PhDs have done. Besides the new subject area, the underlying assumption of research is also different; mainstream IS studies assumes that scientific knowledge ought to be "objective" (Walsham, 1995); instead, feminist researchers (e.g., Haraway, 1991) suggest that knowledge is situated in the knower and his/her standpoint also in the case of scientific research; the two above-mentioned female PhDs endorse this line of thinking. After taking a PhD, one of them changed to work in another university and the other one changed her research area to be more compatible with the mainstream of CSUT.

Besides liberal feminists' and eco-feminists' explanations for gender bias in CSUT, we can also find explanations which are based on seeing technology as masculine culture. When women are educated to male work (as is the case of CS), they encounter a credibility problem; they are not seen as professionals in a male area (Kolehmainen, 1999, p. 147). The claim that there do not exist any qualified female candidates for open posts in CSUT can be seen in this context, which means that no matter what education and how many publications women have, they are not seen as qualified as men. In this context, the above explanations of gender bias in CSUT can be seen as a part of the process in which the existing masculine images are reproduced and renewed.

HOPES—BUT NO PROMISES—FOR CHANGE

A great deal of work has been done to remove the gender bias, and we can see some good results. The number of female PhDs has increased. Also, some positive development has taken place in CSUT: some female PhDs have obtained posts—at the beginning of 2002 there where none. In recent years, women have started to get more funded posts in post-graduate schools. At the end of 2004 there were five men and four women pursuing funded post-graduate studies in CSUT.

There are female PhDs but they are not seen as qualified enough. The evaluation of someone's qualification is made by other members of the scientific community. Becoming a member of the community is essential, but female post-graduate students get less support from senior colleagues than their male counterparts (Husu, 2001). The result is that female PhDs are not seen as qualified academics but they are seen as women—and the stereotypical image presents women with a lack of technical competence (Gill & Grint, 1995).

CONCLUSION

Although recruiting "more girls for IT" is a common target, still, at the same time, it seems that the existing gender bias is reproduced in many ways. I described a current case in Finland, which is a country with a strong rhetoric of gender equality. In the case, the gender bias is as strong as in the USA in the 1990s (Camp, 1997). The causes for bias can be found at many levels—in individuals, workplaces and society. The situation becomes worse as the whole picture is not seen, but different stakeholders see only one aspect of it. The thought-models of the decision-makers in CSUT follow the liberal feminist approach; they ignore social structure and attribute the problem mostly to women themselves. According to them, gender bias is women's own choice. Regarding women's qualifications, the eco-feminist view is followed: women's knowledge is seen to differ from men's; in CSUT women's knowledge is deemed more limited. According to eco-feminists, women's knowledge is better, but in the case of technology it is more limited.

The previously stated views do not focus on gendering processes, as does the approach of seeing the relationship between gender and technology as a cultural phenomenon. In this context, everyday actions are seen in relation to strengthening or questioning the existing gender structure. Every woman who writes a doctoral dissertation in CS takes a small action towards challenging the old gender structure and towards changing the existing gender bias. However, the reproductive process includes opposite actions as well; every case of ignorance among qualified women in the filing of posts reproduces the existing gender bias.

KEY TERMS

Academic Professional: A person who has a PhD degree and whose qualifications are evaluated and accepted by other academic professionals in the same field.

Computer Science: An academic discipline which is focused on computer software, including programming, algorithms, and databases. In Finland, computer science also includes organisation and human centred IS science.

Eco-Feminism: Sees women as being essentially close to nature. Women's biology, it is argued, has led to a specific way of 'knowing' and experiencing the world, based on emotions, intuition and spirituality. According to this perspective, society is made up of two discrete cultures—a male (patriarchal) one and an undervalued female one (Gill & Grint, 1995, pp. 5-6).

Gender Bias: Exists when, in some situation, women's and men's number, status and treatment differs to such an extent that it is disposed to favour one side (mostly men) against the other.

Gendering: A process in which gender images, norms, expectations are constructed.

Liberal Feminism: An approach of gender and technology studies which focuses on reaching equal access to technology and recruiting more women for technical fields. As technology is seen to be neutral, the main problem is women's attitude (Gill & Grint, 1995, pp. 6-8; Vehviläinen, 2000).

Technology as Masculine Culture: An approach of gender and technology studies, which includes the understanding of masculinity as an abstract frame of reference; a kind of standard one applies to the articulation of one's own as well as other people's gender. Men can use technical objects to demonstrate masculine capacities as they arouse associations of masculinity in others (Lie, 1995, p. 382; Wajcman, 1991, p. 143).

C

Critical Research on Gender and Information Systems

Eileen M. Trauth
The Pennsylvania State University, USA

Debra Howcroft
University of Manchester, UK

INTRODUCTION

In 1991 Orlikowski and Baroudi published a seminal paper about the role of epistemological lenses in shaping information systems (IS) research. Citing Chua's (1986) classification of research epistemologies they went on to describe the way in which each of three lenses—positivist, interpretive, and critical—influences the conduct of IS research. They concluded with the observation that whereas positivism dominated the IS research landscape, interpretive research was beginning to make an appearance. They also noted the dearth of critical IS research. Throughout the 1990s a few papers on critical research appeared. Myers' (1997) paper on critical ethnography helped to bridge the understanding gap between interpretive and critical research. Ngwenyama and Lee (1997) used the critical lens to guide their approach to examining information richness theory. Doolin (1998) argued that a research approach based on critical theory is needed in order to view information technology within a broader context of social and political relations. However, in the 2000s there has been a significant increase in the focus on critical research, as evidenced in an increasing number of publications, conference streams, special issues, and academic electronic networks concerned with discussing critical IS[1].

It can be argued that the social nature of activities associated with the development, implementation, and use of IS and the management of people who carry out these activities leads naturally to considerations of social and political power. This consideration of power, in turn, encourages critical analysis. In the social sciences the term critical is used to describe a range of related approaches, including critical theory (Horkheimer, 1976), critical operational research (Mingers, 1992), critical ethnography (Forester, 1992), and critical management studies (Alvesson & Willmott, 1996). Despite some areas of commonality, critical researchers draw upon a broad range of social theories. These include, for example, the Frankfurt School of critical social theory (Horkheimer, 1976), actor-network theory (Latour, 1991), Marxism (Marx, 1974), feminist theory (Wajcman, 1991), and the work of Bordieu (1990), Dooyeweerd (1973), Foucault (1979), and Heidegger (1953).

BACKGROUND

It can be further argued that the topic of gender and IS is particularly suitable for critical research insofar as it is concerned with power relations and underrepresented voices in the context of gender and information technology use (Kvasny & Trauth, 2002). The choice of a critical rather than a positivist or an interpretive epistemology for research on gender and IS, however, has definite implications for both the perspective on the topic and the way it is researched (Howcroft & Trauth, 2004).

When the positivist epistemology is applied to the topic of gender and IT, the objective is typically to discover *whether* and *where* there are gender differences. The aim is to uncover gender distinctions, not to explain or theorize why these distinctions have arisen and continue to exist. Examples of this include investigations of women's vs. men's use (adoption, acceptance, etc.) of IT (e.g., Gefen & Straub, 1997) and women's participation rate in the IS profession (e.g., Carayon, Hoonakker, Marchand, & Schwarz, 2003; Truman & Baroudi, 1994). Further, the theory underlying positivist gender research is often essentialist whereby observed gender differences are understood to arise from the dichotomizing of male/female roles that, in turn, are assumed to generally derive from bio-psychological differences (Wajcman, 1991).

Much of this research is predicated on negative assumptions about women (such as assumptions that women are inherently less technologically competent than men) and is not typically informed by the gender literature (Adam, Howcroft, & Richardson, 2004). This type of research is typically motivated by a desire to advance managerial objectives. For example, it might be to consider gender as a factor of production in better harnessing diversity in pursuit of effectiveness and productivity (e.g., Gallivan, 2003; Igbaria & Baroudi, 1995; Igbaria & Chidambaram, 1997; Venkatesh & Morris, 2000). Problems of inequality are viewed in terms of wasted resources, with increased equality being promoted as a means of optimizing efficiency. The main drawback of this research approach is that the investigation remains on the surface of observable and documentable differences. In so doing, it offers an unproblematic treatment of the topic in which the observation of differential treatment in the workplace by gender has a tendency to become the explanation (i.e., that men and women are treated differently in the IT workplace *because* they are different with respect to their relationship to IT and IT work in some relevant, essential way). Further, by offering only managerialist perspectives, positivist gender and IS research privileges one perspective over others. Hence, the gendered aspects of IT use, for example, are not considered from the perspective of those experiencing it.

In contrast, interpretive studies of gender and IS focus on developing a better understanding of *how* these gender differences in IT use and IT work have come about. The objective is to add context to the observations about gender and IT. This research invokes such theories as social construction (e.g., Nielsen, von Hellens, Greenhill, & Pringle, 1998; Tapia, 2003) or individual differences (Trauth, 2002; Trauth, Quesenberry, & Morgan, 2004) in developing theoretical explanations that incorporate social influences underlying inequality (e.g., observable differences) between the genders. The point of view of this research is not just managerialist; the motivation is also to advance our understanding of the relationship between gender and IT by understanding the point of view of the women IT users. Thus, an interpretive examination of gender and the IS profession might explore the influence of national culture on the social construction of gender identity as it relates to the IT workforce (Trauth, 1995; Trauth, Nielsen, & von Hellens, 2003; Trauth, Quesenberry, & Yeo, 2005). However, a limitation of the interpretive approach is that the focus is on *understanding* the societal influences, not *questioning* them. It is directed at coping with the dynamics of inequality, not challenging the legitimacy of underlying social influences or undoing them.

MAIN THRUST OF THE ARTICLE

In response, the objective of critical gender and IS research is to investigate *why* gender inequality exists. The motivation is to understand and challenge power relations that reproduce inequality (Kvasny, in press). Critical social theory, postmodernism, and feminist theory (Adam 2002; Adam & Richardson, 2001; Kvasny, Greenhill, & Trauth, 2005), for example, are used to inform the search for the underlying causes of gender inequality. Thus, a critical perspective on gender and IT might concentrate on the gendered nature of the workplace and technological skills (Wilson, 2002). This moves the research away from positivist and interpretive themes of profitability, efficiency, effectiveness, and gender identity, and towards themes of control, resistance, and inequality.

Critical researchers also embrace the social and political influences on their research, rather than negate these assumptions and beliefs. They aim to balance their interest in the people being studied with an awareness of less explicit ideological and structural forces. This is in contrast to what Bhaskar (1979) has described as the “linguistic fallacy,” the claim adopted by many interpretivists that subjects, concepts, meanings, and accounts of their actions cannot be criticized. In critical research the spotlight shifts from an exclusive focus on individuals, situations, and local meaning to the systems of relations, which make such meanings possible. This is not to suggest that experiences are ignored; rather they are balanced against issues of an ideological nature that may frame the experiences and ascribe additional meaning.

The use of critical IS research to study the topic of gender and IS enables new explanations and theories to become available. It addresses positivist limitations by offering alternatives to managerialist perspectives and theories. It addresses interpretive limitations by considering power relations, marginality, and dominant discourses in the organizational and societal context. The use of critical theories enables the researcher to shed theoretical light on the subtle ways in which gender inequality is operationalized in technological disciplines in the academy and the workforce.

CONCLUSION

While the use of a critical epistemology for research on gender and IS would seem to flow naturally from the nature of the topic, there is surprisingly little critical gender and IS literature, with some notable exceptions.[2] This situation suggests a fertile area for future research. In making the choice of a critical epistemology, however, it is important to recognize the methodological implications of doing so. First, while there is little critical gender and IS literature, there is even less empirical critical gender and IS research literature. This dearth of empirical research means that there are few examples in the literature upon which researchers can currently model their work. Second, whereas positivist research endeavors to remove bias from the research account, both interpretive and critical research acknowledge the inherent bias in all research. But because of the agenda of highlighting the power dynamics at work in organizations, critical research is typically more vulnerable to political issues when attempts are made to publish such work. The diffusion of critical research in IS is being enhanced by critical IS books, critical IS conferences, and special issues of journals on critical IS, which provide new outlets for the dissemination of critical IS research. It is hoped that at least some of this emergent research will address the topic of gender and IT.

KEY TERMS

Actor-Network Theory (ANT): Developed by Michel Callon and Bruno Latour, ANT is a social theory that explains the interrelated connections between human and nonhuman actors. At the core of this theory is the understanding that technology and society are mutually constitutive.

Critical Research: Research that critiques the status quo through the exposure of what are believed to be deep-seated, structural contradictions within social systems, thereby transforming these alienating and restrictive social conditions (Orlikowski & Baroudi, 1991, p. 5-6).

Feminism: A social, political, economic and intellectual movement that is concerned with removing the subordination of women. With regard to research, feminism searches for ways in which women's positions in life can be made equal with those of men (Adam, 2002).

Feminist Theory: According to Wajcman (1991), there is no single "feminist theory" but rather a diversity of perspectives including: cultural feminism, eco-feminism, liberal feminism, postmodernism, radical feminism and social feminism. This body of theories argues that inquiry should be based on the "lived sociopolitical experiences of women" because their perspectives afford an alternative view of social relations to that of mainstream empirical epistemologies (Schwandt, 2001, p. 93).

Interpretive Research: Research directed at understanding the deeper structure of a phenomenon within its cultural context by exploring the subjective and intersubjective meanings that people create as they interact with the world around them (Orlikowski & Baroudi, 1991, p. 5).

Positivist Research: Research that assumes the existence of *a priori* fixed relationships within phenomena which are typically investigated with structured instruments. The purpose of this research is primarily to test theory (Orlikowski & Baroudi, 1991, p. 5).

Postmodernism: An intellectual movement that rejects modernist principles and practices. It argues, instead, that there is no single truth or reality. Since multiple versions of truth or reality exist, it argues for pluralist principles and practices (Webster, 2002, Chap. 9).

ENDNOTE

1 An example of books is Howcroft and Trauth (2005). Examples of special issues of journals devoted to critical research include *Data Base* (2001/2002), *Journal of Information Technology* (2002), and *Information Systems Journal* and *Information Technology & People* (forthcoming). Examples of conferences with a critical IS stream include the Critical Management Studies conference (1999, 2003, 2005), Critical Research in IS Workshops (2001, 2004), and a critical stream at the Americas Conference on IS since 2001.

The Cross-Cultural Dimension of Gender and Information Technology

Haiyan Huang
The Pennsylvania State University, USA

INTRODUCTION

The underrepresentation of women in the information technology (IT) sector has been widely studied in the contexts of western countries such as North American and Western European countries. These studies indicate that the underrepresentation of women in the IT sector is unveiled in multiple perspectives, including IT access, the development, adoption and use of IT, IT education, and the IT workforce in general and within the IT workforce structure itself (e.g., different levels of IT positions) (Cooper & Weaver, 2003; Gürer & Camp, 2002; Hartzel, 2003; Klein, Jiang & Tesch, 2002; Margolis & Fisher, 2002; Rommes, 2002; Trauth, 2002; von Hellens, Neilsen, & Beekhuyzen, 2001; Webster, 1996).

Why is it important to study issues related to gender and information technology? First, it is argued that the information technology sector should value and leverage all kinds of diversity (including gender diversity as one dimension) to enhance productivity, to facilitate IT innovation, and to develop IT for a wide variety of people (Avgerou, 2002; Roberts, 2003; Trauth, Huang, Morgan, Quesenberry, & Yeo, 2006). Second, it is also argued that women's underrepresentation in and exclusion from information technology can be attributed to power and socio-cultural reproduction of inequality through technology development and use, and the historically social-construction of technology fields as "masculine" domains, which result in a gendered digital divide (Cockburn, 1985; Kvasny & Trauth, 2002; Kvasny & Truex, 2001; Wajcman, 1991, 2004; Woodfield, 2000). Ignorance or failure to address issues related to gender and IT will further marginalize women's participation in future economic and social development, and will endanger social equality and social welfare in general (Kvasny & Trauth, 2002).

A significant trend of the contemporary information technology industry is towards globalization, which is manifested through a variety of established practices such as IT offshore outsourcing, global software development, and innovation through global R&D (research & design) collaboration (Sahay, Nicholson, & Krishna, 2003; Walsham, 2000, 2001, 2002). Such a globalization trend of the IT industry and market has put forward new challenges to gender and IT research, to incorporate the cross-cultural dimension. Similar to the rationale for studying gender and IT in developed countries (leveraging diversity and improving social inclusion), Hafkin and Taggart (2001) argued that it is imperative to examine the cultural factors while studying gender and IT in developing countries.

Although the research on the cross-cultural dimension of gender relations with information technology is limited, Galpin (2002) pointed out that the underrepresentation of women in IT seems to be a worldwide phenomenon indicated by statistics. Galpin (2002) also pointed out that there is a wide range of participation in IT by women, which is influenced by complex cultural and societal factors that are different from country to country. Models related to gender relations to IT developed in certain socio-cultural contexts may not be applicable to others (Clarke & Teague, 1994a; El Louadi & Everard, 2005; Mukhopadhyay, 1996, 2004).

In addition to the importance of studying gender and IT within a specific cultural context, there is another perspective of the cross-cultural dimension of gender and IT: the increasingly diversified global IT workforce as a result of the IT skill shortage, global IT outsourcing, and other global IT collaborations. For example, under the pressure of the skill shortage of the IT workforce in America, the IT institutions and industry turn to the global intellectual pool for recruiting talented international students and skilled IT workers through F-1 and H1-B visas (National Research Council, 2001). According to the 2005 ITAA (Information Technology Association of America) report, the representation of Asian IT workers in the IT workforce doubled the number of Asian worker in the overall workforce in America (ITAA, 2005). Globally, an increasing number of countries have a maturing IT sector, which enables them to enter the global IT outsourcing market or to engage in globally distributed collaborative software work through virtual environment (Trauth et al., 2005). The mobility and cultural diversity of the global IT workforce will add more complexity to articulate their gender relations to IT since individuals may have different cultural backgrounds and experiences.

Therefore, it is important for scholars and practitioners to explore the cross-cultural dimension of gender and IT to understand how the nuances of different cultural influences shape women's relations with IT, to build knowledge with respect to the plural perspective of gender and IT research, and to prepare future global IT workforce. In this article, I first articulate the theoretical underpinnings of cross-cultural dimension of gender and IT research, then review some current studies related to this research area, and finally discuss some future research agendas.

BACKGROUND

The theoretical explanations about why women are underrepresented in IT education and the workforce are complex in nature (Adam, Howcroft, & Richardson, 2002, 2004; Webster, 1996). Those theories attempt to articulate the gender IT gap from either the technology perspective (including the IT sector environment) or the people perspective (e.g., women). From the technology perspective, there are two theoretical orientations: technology determinism and social shaping of technology. From the people perspective, there are three theoretical orientations: essentialist theory, social construction theory, and Individual Difference Theory of Gender and IT (Trauth, Quesenberry, & Morgan, 2004).

Technology determinism views technology as a value-free artifact without any biases, and the impacts of technology on society are self-directed and universal. It neglects the influences of socio-cultural contexts in which the technology is created and used. Social shaping of technology, on the other hand, views technology as a product of socio-cultural and power relations and the impacts of technology on society are shaped by the socio-cultural beliefs embedded within the technology and the societal attitude towards the technology. For example, Kvasny and Truex (2000) argued that power relations and controls are embedded in technology and in society's attitudes towards technology, and hence new technology tends to "reify the dominant relations in the existing social order." The embeddedness of social order in technology will privilege certain groups while disempowering others (Kvasny & Trauth, 2002). Technology related educational disciplines and industrial sectors have been historically dominated by men and hence are embedded with belief systems that are engendered with "masculinity," which may be exclusive of women's participation (Cockburn, 1985; von Hellens et al., 2004; Wajcman, 1991, 2004). Driven by this theoretical orientation, researchers recommend bringing IT closer to women: changing technology development methods, increasing women's participation in system development and implementation, modifying the "masculine" culture of IT at various levels from societies, to industries, and to organizations and educational institutions.

The essentialist theory argues that men and women are differentiated by their biological differences; such differences are inherent and fixed and thus act as main causes to determine their different relationships with IT (Adam et al., 2004; Trauth et al., 2004). Similar to the technology determinism, the essentialist theory only emphasizes the intrinsic internal differences between men and women and overlooks the influences of social contexts in which both technology and people are embedded. Social construction theory views gender identity and gender relationship with IT as on-going negotiation processes in social interactions, in which the influences of various factors are relevant and important (Trauth et al., 2004; von Hellens et al., 2004; Wajcman, 1991; Webster, 1996). Driven by this theoretical orientation, researchers recommend bringing women closer to IT, which include setting up mentoring programs, providing convenient child-care facilities, and developing initiatives to facilitate work-life balance of female IT workers.

Trauth (2002) pointed out that social construction theory of gender and IT tends to separate men and women as two separate socio-cultural groups, which mainly focuses on the differences between the gender groups while overlooks the differences within the gender group. Within the gender group, differences such as ethnicity background, family, social class, individual life experiences, age, individual personality and attitude also play important roles in shaping one's relationship with IT (Kvasny, 2003; Trauth et al., 2004). Trauth argued for focusing on individual level of analysis and developing Individual Difference Theory of Gender and IT (Trauth, 2002; Trauth et al., 2004).

MAIN THRUST OF THE ARTICLE

Theoretical Underpinnings of Cross-Cultural Dimension of Gender and IT

In his research on cross-cultural information systems production, use, and management, Walsham (2001, 2002) emphasized the importance of examining the cultural diversity and argued that the existing local socio-cultural context is a critical factor in mediating the globalization process in a specific context and, in turn, will have an impact on the complexity of globalization. Similarly, to study the cross-cultural dimension of gender and IT, the underlying theories should be sensitive to and account for the dynamics of cultural diversity. Evidences show that cultural diversity and its influences on gender and IT is connected to three theoretical perspectives: social construction of gender relationship with IT, social shaping of technology, and Individual Difference Theory of Gender and IT.

El Louadi and Everard (2005) examined current labor force condition of Arab countries, and more particularly Arab women. They pointed out that because of the Arab cultural influences, the future opportunity of engaging Arab women in IT work may lie in telework, which can bring work and information technology into the home where Arab women can be professionals and care for the family at the same time. This is an example of the distinct Arab socio-cultural influence on women's relationship with IT.

Nielsen et al. (1998) studied non-Asian and Asian female students enrolled in IT disciplines in Australia and the differences among their perceptions of IT educations and careers. Their study showed that both non-Asian and Asian females had similar views about the IT professions. However, Asian female students were more inclined to choose IT related subjects despite their negative perceptions of IT professions because of the future prospects of employment opportunities (Nielsen, von Hellens, Greenhill & Pringle, 1998; Nielsen, von Hellens, Pringle & Greenhill, 1999). Such a choice is influenced by collectivist characteristic of Asian culture and is based on practical consideration, as compared to the "free-choice" decision making in most Western cultures. The research by Geary on comparing children's mathematic achievements in different countries also supports this argument (Geary, 1996; Geary, Bow-Thomas, Liu & Siegler, 1996): Asian culture emphasizes practical reason (e.g., usefulness) in decision-making while Western culture emphasizes free choice. The studies by Nielsen et al. (1998, 1999) indicate that although the perceptions of IT professions might be similar between Asian and non-Asian women (e.g., the social shaping of technology is similar), their relationships with IT are different because of the cultural influences. Also their studies are situated in one national context, Australia, which implies that researchers should pay close attention to the differences within gender groups (in this case, Asian and non-Asian Australian female IT students). It also implies that cross-cultural influence is an important dimension in studying the Individual Difference Theory of Gender and IT.

An early study by Clarke and Teague (1994a, b) is also about the Australian context. Based on interview data, their study shows that Asian female CSE (Computer Sciences and Engineering) students did not see computing as a male domain and they also received direct encouragement from family to pursue computing related secondary studies. This is an example of cultural influences on both social shaping of IT and social construction of gender relationship with IT. Clarke and Teague (1994b) pointed out that "the differences within gender groups are greater than the differences between gender groups" (p. 259), which indicates the relevance and important in studying the individual difference of gender and IT.

The study by Mukhopadhyay (1996, 2004) also strongly supports considering a cross-cultural dimension in studying gender and science (although IT is not a central subject in this study, it is closely relevant). Mukhopadhyay (1996, 2004) challenged both the essentialist theory and those American theories of gendered science that embodied long-standing American cultural models to other socio-cultural contexts. She pointed out that it is the Indian cultural model of family, gender, and science that influences the Indian women's academic decision-making process, and hence results in a predominantly male scientific community in India. Mukhopadhyay (2004) also stressed that:

We need to explore the processes through which individuals internalize and utilize what Strauss and Quinn (1997) call "public culture" as it relates to gender, schooling, academic subjects (mathematics, science, etc.), family, kinship, and marriage. We need to understand more about how and why some messages have more motivational force than others, for some girls more than others, and how they mediate math and science attitudes, achievements, and choices. (p. 487)

Current Research on Cross-Cultural Dimension of Gender and IT

A comprehensive review of current research on cross-cultural dimension of gender and IT is beyond the scope of this article. Here, I would like to provide a brief overview. Current research on cross-cultural dimension of gender and IT can be classified into two categories. One category consists of comparison studies that investigate how and why the women's participations in IT are different in different countries. The study by Galpin (2002) provided a good summary and references for this type of study. Another example is the study by Hafkin and Taggart (2001), which focuses on studying the developing countries. The primary objectives of those studies are: to understand the nuances of different socio-cultural influences on gender and IT in different countries; to come up with solutions to improve women's participation in IT that fit with a specific socio-cultural context; and to see whether or not some practices and experiences can be transferred from one country to another country.

Another type is to situate the cross-cultural dimension of gender and IT within a specific societal context while studying how the diverse cultural backgrounds of different women may influence their relationships with IT. The studies by Clarke and Teague (1994a), Nielsen et al. (1998, 1999), and by Mukhopadhyay (1996, 2004) are the examples. The primary objectives of these studies are to critically address the cultural influences on women's relationships with IT within gender groups, and to leverage the influences of cultural diversity on IT to a great extent. The number of this type of study is limited compared to previous types. However, the importance of this type of research is increasing due to the globalization of the IT market and industry and the mobility of IT professions.

FUTURE TRENDS AND CONCLUSION

In this article, I argue that it is important to investigate the cross-cultural dimension of gender and IT because of the contemporary globalization phenomena. From the theoretical perspective, I discuss how the cross-cultural dimension can be incorporated into the social shaping of technology, social construction of gender and IT, and individual differences perspective on gender and IT. However, the number of studies in cross-cultural dimension of gender and IT is limited.

Therefore, one of the future research agenda items is to have more studies in this area to address the influences of cultural diversity. Another future research agenda item is to further incorporate the cross-cultural dimension into the theoretical developments of gender and IT. To do so, we need to encourage interdisciplinary discourse among different disciplines, and also global collaborations in gender and IT research.

KEY TERMS

Essentialism: The assertion of fixed, unified and opposed female and male natures (Wajcman, 1991, p. 9). This theoretical perspective is used to explain the underrepresentation of women in the information technology field by arguing the existence of "essential differences" between males and females with respect to engagement with information technology.

Individual Differences Theory of Gender and IT: A social theory developed by Trauth (Trauth, 2002; Trauth et al., 2004) that focuses on within-group rather than between-group differences to explain differences in male and female relationships with information technology and IT careers. This theory posits that the underrepresentation of women in IT can best be explained by considering individual characteristics and individual influences that result in individual and varied responses to generalized environmental influences on women.

Social Construction: A theoretical perspective articulated by Peter Berger and Thomas Luckmann (1967) that focuses on social processes and interactions in the shaping of actors. This theoretical perspective is used to explain the underrepresentation of women in the information technology field by arguing that technology—socially constructed as a masculine domain—is in conflict with socially constructed feminine identity.

Crossing the Digital Divide in a Women's Community ICT Centre

Clem Herman
The Open University, UK

INTRODUCTION

This article examines the role of community-based training initiatives in enabling women to cross the so-called digital divide and become confident users of ICTs. Drawing on a case study of the Women's Electronic Village Hall (WEVH) in Manchester, United Kingdom, one of the first such initiatives in Europe offering both skills training and Internet access to women, the article will illustrate the impact that community-based initiatives can have in challenging and changing prevailing gendered attitudes toward technology. Gendered constructions of technology in dominant discourse suggest that women must also cross an internal digital divide, involving a change in attitude and self–identification, before they can see themselves as technically competent. Learning about technology is intimately linked to learning about gender, and the performance of skills and tasks that are culturally identified as masculine can be an empowering step for women, successfully challenging preconceived gendered relationships with technology.

The WEVH occupied a unique position, acting as a model for other women's ICT initiatives and influencing the development and proliferation of other community-based ICT access projects. There were two main motivating forces behind its setting up in 1992. The first was a shared vision of the potential for ICTs to be used as a tool to combat social exclusion. The second was a feminist commitment to redressing the inequalities and underrepresentation of women in computing. Both these perspectives formed an important backdrop to the growth and development of the organisation and have continued to inform its strategic plans.

BACKGROUND

The Digital Divide

The context in which the WEVH was set up in the early 1990s was the first wave of initiatives concerned with tackling the so-called digital divide. During the decade that followed, there was a proliferation of initiatives driven by both British government and European policy aimed at ensuring that the emerging information society was inclusive of all citizens including specific measures for the participation of women.

While the personal ownership of PCs (personal computers) and home-based access to the Internet has increased at a rapid pace in Britain since the early 1990s, it is still the case that significant sections of the population do not have access to computers or the Internet. Moreover, those who are digitally disadvantaged often do not have the skills to take advantage of the potential that ICTs have to offer[1] (Office of National Statistics, http://www.statistics.gov.uk). Community-based ICT facilities to tackle the so-called digital divide were seen as one of the key strategic tools in community development and urban regeneration that was reflected in policies at the local, national, and European level. [2]

During the first wave of measures to tackle the digital divide in Europe in the early 1990s, women were considered one of the primary target groups for ICT training and access. The emerging Internet at that time was predominantly used by "techie" men, designed and implemented without the perceived need for inclusive strategies, and immersed in a strongly male-identified culture. At the time of its creation, the WEVH was therefore responding to a clear need to tackle gender inequality, an issue that was considered self-evident to all concerned. Over a decade later, following the transformation of user interface design and the creation of the World Wide Web, Internet access reached the majority of the British population, and there is now only a small difference in usage between men and women (Citizens Online, 2005).[3] While this is certainly an improvement, this simple analysis of Internet usage ignores the realities of women's continued underrepresentation in the IT industry, from their lack of influence on content and applications development to widespread inequalities in women's employment opportunities in IT. Yet it seems that the increase in women's access to the Internet and basic ICT skills has seen a reduction in public commitment to resources for women-specific ICT initiatives, which had historically been justified by the statistics of Internet usage.

While quite rightly addressing important social-exclusion issues, the notion of the digital divide as it has been used in British policy debates is somewhat limited, assuming a one-way process in which access to a computer and the Internet enables individuals to cross over and join the digitally empowered. However, there are significant numbers of ex-Internet users or refusers, that is, those who have stopped using the Internet either by choice or because they no longer have access: "It is clear ... that overall growth patterns of Internet usage conceal significant changes in usage by different sub-populations, including some evidence of drop off by particular groups" (Woolgar, 2000, p. 5).

Community ICT Access

The creation of the WEVH was part of a growing movement of community ICT initiatives that were developed at the local level both in Britain and elsewhere in the early 1990s. All of the initiatives had the common aim of providing "supported access in a location other than work or home" and "access to ICT in a social context" (Liff, Watts, & Stewart, 2000, p. 2-3). They have been known by a range of names including e-gateways, telecottages, telecentres, electronic village halls (EVHs), ICT learning centres, cybercafes, telework centres, community teleservice centres, and so on.

The idea of the electronic village hall was based directly on a model pioneered by Lars Qvortrup in Denmark, and was influenced by a growing counter-culture in the USA of online community networks and bulletin boards such as The Well (Rheingold, 1995). The creation of urban electronic village halls was part of a vision for the city of Manchester that combined community grassroots involvement with a local-authority public-information service known as the Manchester Host, an e-mail and bulletin-board system that local people could connect with and use to communicate with each other that would have shared community space as well as online databases supplying information. A cornerstone of the vision was that local people who did not have access to computers in their homes would be able to use these services at community access points: There were already some examples of these kinds of community centres operating successfully in rural Scandinavia. The concept of an electronic village hall in Manchester was a deliberate attempt to adapt the concept of a rural telecottage into an inner city context (Leach & Coppitch, 2005). The name implied that the centres would function as cozy, friendly local meeting places where technology could be made accessible and simple to use. In 1990, there was no World Wide Web, just text-based, command-line interfaces, so it was imperative that there were people to enthuse and support new users who might find the technology intimidating. The centres would be staffed by enthusiastic "telemateurs" who would raise awareness and act as missionaries within the communities. This was very important: The projects were not responding to expressed needs, but were proactive in trying to create those needs and a critical mass of users on the Manchester Host. As well as the WEVH, two other electronic village halls were set up in geographical neighbourhoods, providing services to spatial rather than virtual communities. The EVHs were charged with wide-ranging social and economic aims, including a regeneration agenda supporting and encouraging the development of local communities and businesses through the use of ICTs.

Women and ICT: Finding a Space

While this political context in the city of Manchester was one strand in the WEVH story that informed its strategic and financial development, it was the feminist agenda of empowering women through the use of technology that formed the core of the organisation's vision. In looking at how the experience of the WEVH connects with theories about gender and technology, it is possible to trace a changing awareness and perspective within the organisation during its historical development, which reflected changes in external environments and political climates within what might loosely be called the women's movement in Manchester.

The original proposal for the WEVH was to house the project in a women's community centre, a building that had been home to the famous Pankhurst family. (Emmeline Pankhurst and her daughters were leaders of the British suffragette movement in the early years of the 20th century, and their house became an important focus for the women's movement in Manchester in the 1980s.) However, differing perceptions and attitudes toward technology resulted in the project being located elsewhere. Existing workers at the centre who had been immersed in the political struggles of the 1980s adopted what could be described as an ecofeminist position: They saw technology as something to resist rather than embrace and were afraid the project would take over the work of the centre. There was a level of technophobia that sprang from a tradition of radical feminism in which technology was to be resisted as part of the patriarchal, military, industrial complex, a biologically determinist viewpoint advocated by writers such as Susan Griffin and Adrienne Rich (Grint & Gill, 1995). The 1980s women's movement had been characterised by peace and antinuclear protests, the emergence of green and environmental causes, anti-capitalism, and a celebration of women's creative diversity. The new information and communication technologies were seen to be associated with masculine values and were perceived as a threat to hard-won women's space.

Equality of Opportunity

In fact, from its inception, the WEVH can be seen to have subscribed to a liberal feminist agenda in relation to technology (Henwood, 1993) in that the aim was to get more women into technology by increasing the supply of skilled women. Women were identified as lagging behind in their involvement with new technologies, and the new centre would help them catch up by offering special programmes of training. This approach came through the conviction that providing opportunities for skills development would bring about change and was consistent with the dominant equality-of-opportunity discourse current at that time. This was an approach prevalent in women's training centres throughout Britain, which provided access to training in nontraditional skills. This agenda was also overtly highlighted in the criteria of funding agencies. Many of the training and research projects were funded by the European Union and were based on the underlying justification that there were skills shortages in a particular industry (in this case IT) and women were underrepresented in these occupational sectors. The solution was to increase the number of women in these sectors by encouraging them to develop skills and enter work in ICT. Training was carried out within a culture of nurturing and supporting women, which drew on traditional feminist pedagogical methodologies—peer support group, personal growth and consciousness raising, a celebration of the hidden achievements of women in history, and so on (Ellen & Herman, 2005).

While individual women certainly achieved personal success, not surprisingly, very little change was brought about to the gender balance in the IT industry as a whole. Although women consistently found employment directly after their training (http://www.wevh.org.uk), only a handful of women went into areas of IT that were highly gender segregated such as computer networking. Those women who went on to study computing or IT in higher education mainly went into so-called "soft" or hybrid degrees, not into the traditionally male-dominated subjects such as computer science. This is hardly surprising given the scale of the problem: The equal opportunities or liberal feminist agenda, the "women-into" approach, has not generally been successful in achieving the large-scale restructuring of gendered occupational segregation in technology (Ellen & Herman, 2005). In fact, any attempts to rectify the unequal gender balance in segregated occupations without tackling underlying cultural norms seem destined to remain marginal in their impact.

Cultural change is necessary at both the macro and micro level. Parallel to the discourse of equal opportunities and the liberal feminist analysis of gender and technology, the WEVH can be seen as having the more subversive strategy of challenging the perception of "technology as masculine culture" (Wacjman, 1991, p. 137). Understanding technology as culture (both as the work environment in which technology is used as well as the artefacts and hardware themselves) has enabled the organisation to challenge attitudes that women had about themselves and their own expectations. Women experienced participation with technology as an appropriate activity rather than a transgressive act to be resisted. An environment in which trainers and technical staff were all women and learning was experienced in an all-female group provided a stark contrast to the cultural norm of technology as masculine. The women-only training environment was crucial to success: It allowed skills to be acquired in a gender-neutral way without having to refer to dominant cultural assumptions of gender-appropriate knowledge.

Empowerment and Cultural Change

Even within a small-scale environment such as the WEVH, it has been possible to challenge deeply held cultural attitudes. One of the key strategies was to ensure that women had hands-on experience of touching technology, which has often been a taboo activity for women. Throughout all training provision, an emphasis was placed on giving women the empowering experience of handling pieces of technological equipment and to see this as fun and enjoyable. In introductory courses, women had to assemble their own PCs by plugging in the correct leads; in the networking course, women were installing motherboards and fitting new cards, crawling under tables to connect wires. All trainees were taught to carry out routine maintenance and troubleshooting procedures.

These experiences are empowering not only because they develop useful skills, but also precisely because they are transgressive and not what women would have expected of themselves. These women were not performing gender in the way in which they had been used to, and by doing so, they were subverting received notions of gender-appropriate behaviour or performance (Butler, 1999). This empowerment was something that women could transfer to other areas of their lives, and many expressed how they had become more confident and increased their own self–esteem. One woman says, "the training I received at the WEVH has had an incalculable effect on my life…I learnt about the logic behind computer systems which set both my capabilities and my imagination free" (Dyson, 1999, p. 78). By challenging internal stereotypes about the type of knowledge and skills considered appropriate for themselves as women, they could then apply this knowledge to other situations.

A final perspective through which this process of bringing women into a self-confident engagement with technology can be viewed is that of Haraway's (1991, p. 149) notion of the cyborg. As women acknowledge and develop their own relationships with technology through the acquisition of skills, they gain an understanding of and positively embrace the role that technology does and will play in their lives. They recognise that they "are all hybrids of machine and organism…are all cyborgs," and see technology as part of their own future rather than something external to them: "[The WEVH provides] the right atmosphere for any woman, of any background, to attain her best. It made us feel positive about the future, new technology and picture ourselves in it" (Dyson, 1999, p. 75). Opening up opportunities for women to positively use and shape technology has been the ultimate goal for the WEVH; as much as skills and knowledge, it is attitudes that must be changed for this process to succeed.

FUTURE TRENDS

It is clear from this case study that community-based women's training centres such as the WEVH can play a vital role in supporting women to become skilled and confident users of ICT and cross over the digital divide. During the rapid expansion of Internet usage since the late 1990s, the WEVH and similar centres have been important in ensuring gender equality in access to ICTs and pioneering new approaches to empower women in their use of technology. Yet, while Internet usage has now reached the majority of the British population and is relatively equal in terms of gender, there is still a need to support those who are digitally disadvantaged. The lack of Internet access and ICT skills is closely correlated with other indicators of economic disadvantage such as educational achievement, ethnicity, age, and employment status. Thus, for the foreseeable future, there will continue to be a role for women's centres to provide support and empowerment for a significant minority of women who would otherwise not have the skills or confidence to use ICTs. And while the prevailing culture of the IT industry as a whole continues to be male dominated with significantly fewer women employed in this sector, it is important that women's ICT initiatives continue to offer spaces that are free from mainstream gendered constructions of technology, and a basis from which to campaign for change.

CONCLUSION

The original aims and objectives of community ICT initiatives have been clearly tied to an agenda of local democracy and participation. In the case of the WEVH, the fear was that ordinary women would be excluded from participating in the new information society and therefore it was imperative to provide public access points for those without access to equipment at home or at work. But it was always clear that democratisation included not only the means of participation (i.e., hardware and connectivity), but also the skills and attitudes needed to effectively make use of these. For women in particular, there were internal messages and cultural barriers that also had to be overcome. This vision has remained but has had to adapt to a wide range of changes. Technological developments and the wider ownership of PCs have altered the role from one of advocacy and awareness to that of fulfilling expressed needs.

The WEVH has been a unique example of a vision that has survived and grown despite the changing agendas of funding agencies and politicians, a vision of a centre where women can become confident users of technology. Above all, it has played a unique role as a place of personal change and transition for women, an inspiration for other community ICT initiatives, and has created a culture of women using and shaping technology.

KEY TERMS

Cyborg: Originally used to describe human-machine hybrids and commonly found in science fiction, the term was adopted by Haraway (1991) to advocate women's involvement with rather than rejection of technology.

Digital Divide: The division between those who have access to ICTs (particularly the Internet) and those who do not, implying that those without access are disadvantaged. It is used to describe both local and global inequalities.

Electronic Village Hall: A centre providing computers and Internet access for local people or people from a particular community or group. It is also known as a cybercafe, community technology centre, telecentre, or telecottage.

Empowerment: Development of the capacity (either of an individual or a group) to act independently and be able to make and influence decisions and choices affecting one's own life.

ICTs (Information and Communication Technologies): The convergence of computerised information systems with communications technologies, generally used to mean all forms of electronic communication including computers, mobile phones, and other devices.

Information Society: A society in which information and knowledge are central to economic and social life, in contrast to industrial or agricultural societies. The term was widely used by British and European policy makers in the 1990s.

Liberal Feminism: Feminist theory focusing on equal rights and emphasising the removal of barriers to ensure equality of opportunity for all regardless of gender.

ENDNOTES

1 In February 2005, 35% of adults in the United Kingdom had never used the Internet. Of these, 42% had no Internet connection, and 37% felt they lacked the knowledge or confidence to use it. (Office of National Statistics, http://www.statistics.gov.uk)

2 For example, the UK Online initiative in 2000

3 The Office of National Statistics (http://www.statistics.gov.uk) estimated that 64% of men and 56% of women had used the Internet in the 3 months up to September 2005.

Cultural Factors and Collective Identity of Women in ICT

Phyl Webb
University of Tasmania, Australia

Judy Young
University of Tasmania, Australia

INTRODUCTION

There is a considerable body of research to support the longstanding problem of a gender imbalance in the ICT industry (Ahuja, 2002; Baroudi & Igbaria, 1994; Cukier, Shortt, & Devine, 2002; D'agostini, 2003; Frenkel, 1991; Moody, Beise, Woszczynski, & Myers, 2003; Nielsen, von Hellens, & Wong, 2000; Nielsen, von Hellens, & Wong, 2001). However it appears there has been little attempt to draw it together to inform the influences and impacts that many women face when employed in the industry. The objective of this article is to examine research focussing on two factors that have impacted on the experiences of women who have established careers in the ICT industry.

GENDER IMBALANCE IN THE ICT INDUSTRY

The authors conducted a search of the literature related to gender imbalance in the ICT industry. From this, it became apparent that the existing body of literature consistently identified a number of elements as representing the existing state of ICT workplaces. It is possible and perhaps probable that some of these elements are conspiring to influence the:

1. *Cultural factors* typically encountered in ICT workplaces
2. *Collective identity* of women employed in ICT workplaces

Cultural Factors

In reviewing the gender related ICT literature, an image of the tensions that are at work and could influence and impact on women working within the industry emerges. These factors are, in general, subtle. However, they do make a contribution to enhancing understanding by highlighting potential relationships between social pressures to identify reasons and solutions relevant to the current situation within the industry.

Dominant Male Culture

The idea of ICT as a male dominated industry characterised by masculine language and modes of operation is evident from the literature (Pringle, Nielsen, von Hellens, Greenhill, & Parfitt, 2000; The Women in Science Engineering and Technology Advisory Group 1995). A sense of a shared masculine ownership of the science and technology sector as a whole pervades with the result women can feel marginalised and isolated. One outcome of this is a perception that senior men in industry favour males coming in and regard females almost with suspicion and even derision.

The notion of the IT sector as a male domain has conspired to perpetuate a culture of long working hours and masculine language. von Hellens, Nielsen and Trauth (2001) found that while many women did not see IT as an inherently male domain, they reported situations where they had been challenged as a consequence of their sex. In addition, it was noted that many women do leave IT workplaces if they are unable to deal satisfactorily with male domination. Those who remain can be subjected to inappropriate language, advances and stereotyping within the workplace (Teague, 2000; O'Neill & Walker, 2001).

Competitive Atmosphere

Women working in ICT are constantly confronted by the competitiveness of men in presenting themselves and promoting themselves. The preference of women for connections rather than competition may contribute to the levels of discomfort generated within the competitive environment (Lind, 2000). Men can be aggressive and arrogant in the way they compete and reluctant to admit making mistakes or not knowing something. Women tend to find this approach confronting and a challenge to their self-confidence. In general, they tend to have less confidence in their abilities and may be less likely to attempt new activities or activities that are considered challenging. This can have a detrimental effect as it often precludes women from opportunities to demonstrate themselves in a positive light in the work situation. Since these characteristics are valued within the male culture women are disadvantaged as a consequence (Teague, 2000; Cuny & Aspray, 2000).

Demographics of Women in IT within Organizations

As a group women working in ICT workplaces have less organizational tenure, less job tenure and are younger than their male colleagues. Few women hold senior management positions in the sector (Ahuja & Rodlain, 2000; Baroudi & Igbaria, 1994; O'Neill & Walker, 2001; Pringle et al., 2000; Trauth, Nielsen, & von Hellens, 2000). Results from the Association of Professional Engineers, Scientists, and Managers, Australia (APESMA, 2002) survey showed that in the Australian computer profession women outnumbered men in levels 1 and 2 of responsibility and that their representation began to decrease at levels 3 and 4 of responsibility. Further at the higher levels of responsibility (5 and above) men outnumbered women almost to the extent of two to one (APESMA, 2002). In addition often when women achieve seniority in job title this is not reflected in the opportunity to participate in critical IT decision making in the organization and team leadership (Panteli, Stack, & Ramsay, 1991). The exclusion of women from IT management ranks has implications for their career options and probability of better remuneration (Truman & Baroudi, 1994). The distribution of women throughout middle and lower levels in the industry is significant. Panteli, Stack, and Ramsay (1999) reported that even though they might share the same positional role and title as men, women are not engaged in the same projects. Women are more likely to be engaged in administrative functions (O'Neill & Walker, 2001) or in low status specialities such as merging and tidying databases (Pringle et al., 2000).

Effect of Gender Traits

From the literature, it has become apparent that some researchers have concluded that there are specific gender traits and that the existence of these traits impact on the manner in which women assimilate into ICT workplaces. Venkatesh and Morris (2000) explored gender traits in ICT and suggested that men were interested in how useful technology was while women were interested in how easy it was to use. Another gender trait they identified was that women, more so than men, are influenced by peers and others when making decisions to use technology. Women also have a greater need to belong to a group, a greater interest in personal goals and were more responsive to the needs and feelings of others.

For those women who have already chosen to work in ICT workplaces Holmes (1998) found that while men and women do not differ appreciably in relation to many of their work goals, men consider high earnings, variety and advancement as more important than women. Ahuja (2002) has suggested women make choices that see them placed in positions and professions considered female friendly and offers that this may be occurring because of the diversity of roles that women fulfil during their lives. Generally, women prefer a greater balance in their lives.

Balancing Work and Family Commitments

Many women successful in the ICT industry appear to have sacrificed family for work. Even where arrangements exist for women to access flexible working arrangements there is a tendency not to do so. Dowse and Underwood (2001) depicted a negative image for the future of the ICT industry for balancing work and family for both men and women. Historically ICT as an industry has not been sufficiently cognitive of the needs of employees trying to balance paid employment with raising a family (Pearl, Pollack, Riskin, Thomas, Wolf, & Wu, 1990; Truman & Baroudi, 1994). The image of the culture of ICT workplaces is one of long hours often worked outside of normal business hours. So enduring and pervasive has this view become that both men and women have come to expect this regime within ICT workplaces to the point where managers have been reported as rebuffing staff complaints about hours worked because that is just the way it is in IT (Nielsen, von Hellens & Wong, 2001, O'Neill & Walker, 2001). However, the long hours are biased against women (O'Neill & Walker, 2001). Women do shoulder a greater share of the parenting responsibility in most families (Dowse & Underwood, 2001) and because of this expectation it is likely to be a severely limiting factor for females in the ICT industry. To be successful in the industry, women typically need to prioritise work over family (Pringle et al., 2000) while others delay having children until later in life (APESMA, 2002).

ICT as a Solitary and Isolating Career

The image of ICT as a solitary and isolating career still endures. Women tend to favor personal interaction and communication and as a consequence a career that conjures up images of isolation and boredom may be perceived as unattractive (Nielsen, von Hellens & Wong, 2001, Trauth, 2002). The dominant image of the computer nerd is that he is incapable of interacting with people (von Hellens, Pringle, Nielsen, & Greenhill, 2000). Interviews conducted by Trauth (2002) with women working in the IT industry revealed that in order for them to be successful they needed to work alone. This is contrary to the need of women to openly communicate and engage in collaborative approaches (Panteli, Stack, & Ramsay, 1991).

Collective Identity

The second major category identified in the literature is based on examples of literature dealing specifically with the characteristics of women employed in ICT workplaces.

Exhibiting Masculine Tendencies

There is a strong sense within the existing literature that women who are successful working within ICT workplaces have a picture of themselves as being different to most women and more like men in some ways (von Hellens, Nielsen, & Trauth, 2001, Webb, 2002). The women interviewed by Trauth, Nielsen, and von Hellens (2000) who had achieved management positions agreed they have personality traits described as masculine. This happened to the extent that a women professor intentionally aligned herself with the sexist males in order to achieve a "shining career" (von Hellens, Nielsen, & Trauth, 2001).

Further, the women who have achieved in ICT workplaces tend to be more competitive and perhaps as a consequence they do not embrace stereotypical gender roles (APESMA, 2002; von Hellens, Nielsen & Trauth, 2001). They have described themselves as being logical, assertive and task-focussed (Nielsen, von Hellens & Wong, 2001). As one women recounted, to obtain a position in a particular IT organization she felt it necessary to prove that she could 'drink as many beers as the men' (Pringle et. al., 2000, p. 4).

Women Who Use Mentors Tend to be More Successful

There is a lack of mentors and mentoring opportunities for women. As a result many women coming into the industry are denied appropriate role models and the support from other women to whom they can relate (Sumner & Neiderman, 2004; Teague, 2000; von Hellens, Nielsen, & Beekhuyzen, 2004). The shortage of mentors is problematic as this support is crucial to provide positive work experiences in the IT industry and an ability to achieve career success (Pearl et al., 1990).

Ahuja and Rodlain (2000) found a likely connection between the success of women in IT, their intention to remain and advance within the field and the effectiveness of mentoring relationships. von Hellens et al. (2002) cited the example of a young IT professional who was fortunate to have a female team leader. This mentor supported her appointment as a project leader that enabled her to demonstrate her capability in the role and gain acceptance in the organization.

Capacity and Willingness to Adopt Adaptive Behaviours

In the ICT work environment, male personnel are established as the benchmark and women are often forced to adopt masculine behaviours to participate let alone succeed (O'Neill & Walker, 2001). From a constructivist viewpoint, Trauth (2002) states that while women are subject to different social influences, to succeed in the IT environment they need to adjust to work in a male dominated workplace.

From the literature there is an impression that adaptive behaviour may disadvantage a woman in the workplace (Nielsen, von Hellens, & Wong, 2000; Pringle et al., 2000). Pringle et al. (2000) have argued that it should be unnecessary for women to adapt because their organizational and communication skills can challenge the link between technology and masculinity in an IT environment. While this view may have merit the current literature lends little support for the success of women who cannot or will not adapt to the current ICT workplace paradigms.

DISCUSSION

The issues discussed in this article are not claimed to be representative of all actual situations in ICT workplaces. While these have emerged from the literature, it is acknowledged that examples of gender equality cultures do exist in the industry. However, there is ample evidence in the literature to support that generally there is a male dominated culture in the ICT industry.

Gender imbalance is a complex issue and often belies simple explanation and resolution. With respect to the ICT work environment it may be that this domination was established at the very origin of the industry, a time when technology was seen solely as a male activity. Potentially this set a foundation where the notion of homosocial reproduction has perpetuated the situation. Homosocial reproduction implies the politics of the dominant group in the organization will largely drive decisions and actions. While it is possible to change the male domination in the ICT work environment it will be a slow process and to be effective must be embraced by those within the industry. The major barrier is that change will not happen unless there are a sufficient number of women succeeding in ICT workplaces.

If the dominance of the male culture is not challenged, it is unlikely that change will occur. As long as male dominance remains it is central to maintaining the inequitable demographics of women in IT organizations, the competitive atmosphere, the problems of balancing work and family commitments and the solitary and isolating nature of careers in the industry. While there is evidence to support that gender traits can affect the work experiences of women, a change in culture may be more accommodating to the different attitudes and approaches between the sexes.

From a perspective of collective identity it becomes clear that women who do succeed in ICT are those who are willing to be adaptive and get on with their careers. While this tends to involve the adoption of masculine tendencies as a minority group it is probably the only way they can compete on an equal level.

CONCLUSION

The aim of this article was to present an examination of the literature that reports the impact of cultural factors and the influence of collective identity on women who have established careers in the ICT profession. In so doing, it has highlighted some of the issues that have confronted some of the women who have forged successful careers in ICT.

The benefit of this approach is that it offers information to enable women to be better prepared and informed when contemplating a career in the ICT industry. Perhaps this could prove instrumental in reducing the number of women leaving the industry because they are ill equipped to cope in a male dominated work environment. Potentially this may reduce the negative image of the industry. As such it may attract more women to consider careers in ICT and, at the same time, stem the high attrition of women from the industry.

KEY TERMS

Collective Identity: Implies the characteristics exhibited by any group of people in specific circumstances.

Gender: The biological division of the sexes. This division does not consider psychological or other facets of the construct gender.

Gender Imbalance in ICT: The state in which there exists a significant difference between the percentage of male and female participation within the ICT industry. This imbalance extends across most levels of appointment within ICT workplaces.

Homosocial Reproduction: A process in which the politics of the dominant group in the organization will largely control decisions and actions.

ICT Careers: A general term associated with the ICT industry that covers a diversity of roles involving technology, information processing and people issues.

ICT Industry: A business sector focussed on supporting computer infrastructure, people, and information processes within and between organizations.

Organizational Culture: This refers to the shared values, characteristics and rules that govern behavior and attitudes in specific workplace environments. These may be formally or informally applied depending on the nature of the organization.

A Cultural Studies Approach to Gender and ICT

Merete Lie
Norwegian University of Science and Technology (NTNU), Norway

INTRODUCTION

This article introduces a cultural studies approach to the field of gender and ICT. This implies an emphasis on the symbolic aspects of technology. Technologies are approached as cultural phenomena to which meaning is attached, but in the sense that they are open to various interpretations. Technology holds a position as a key symbol in Western societies. A key symbol is, in Sherry B. Ortner's terms, a symbol that helps us to sort out experiences and put them into place within cultural categories, and even help us think about "how it all hangs together" (Ortner, 1973, p. 1341). This key symbol has gone through a radical transformation from mechanical machines to ICTs as the leading technologies. An important question is how changing technologies are linked to another key symbol, namely that of gender. Moreover, following from that question, how can you study the relationship of gender and ICTs when both are continually changing?

THEORETICAL KNOTS

My own background is from a Norwegian network of researchers who have been studying gender and technology for the last 25 years. The differences between two Norwegian collected volumes may indicate a changing direction in the understanding of gender and ICT from the 1980s until today. The volume from the 1980s depicts technology as a tool of power in the hands of men (Lie et al., 1988). This provided a clear line of analysis as well as a direction for action to change the imbalance between men and women's access to technology. A volume from the 2000s, however, depicts a cybernetic pattern with threads and knots and loose ends—and may serve as an illustration of a seamless web with neither one distinct pattern nor one direction for change (Lie, 2003).

In our research during the 1980s, we analyzed technology as a means of power within a gendered division of labor. Technology was analyzed as the result of social constructions with in-built gender divisions, or in David Noble's terms, "frozen culture" (Noble, 1985). At the same time, however, technologies are also messengers, telling us who and what belongs where. During the 1990s, my focus shifted towards the symbolic dimensions of technology and the strong connections between technology and masculinity. As a symbol of masculinity, technology strengthens bonds between men and offers a way of "doing" or "performing" gender. To prove one's competence with technology is to prove one's place as a man among men. This perspective tends however, to be too static and has therefore spurred a search for new perspectives that include changing technologies as well as varying and constantly changing understandings of femininities and masculinities.

Within the field of gender and ICT, most attention has been accorded to women and how one might change their attitudes to technology. Feminists have tried to move away from this one-sided perspective towards regarding it in relational terms, thus drawing attention to technology as the other side of the gender-technology relationship. Instead of changing women, it was argued, one should change technology and the culture of technical institutions. In this way, however, both the concept of gender and that of technology may appear to be given and stable, thus in need of conscious strategies if they were to change. However, what we actually observe is that both are constantly changing. Suffice to mention how computers as calculating machines have been transformed into information and communication devices (Turkle, 1995) and continuing debates about what gender means and proper gender conducts. The challenge is that when we try to find out why gender still matters in relation to ICT, the themes we are dealing with tend to change their shape: gender relations are re-negotiated and new technologies appear. Thus, once we have identified a strategy to include women into the field of ICTs, the whole field is re-configured. Change is therefore obviously, what theories of gender and technology have to include.

Moreover, ICT is no longer an exotic item with the prefix cyber-, alluding to something that is virtual, out of the real world, and exclusively for a minority with access to a cyber society. Today, ICT indicates rather familiar items that are included in the everyday routines of many people, at work, for entertainment, and for social activities. ICT is part of a variety of activities related to different aspects of people's lives. However, we still tend to talk about ICT as if it were one thing.

As mentioned, the studies of gender and ICT have mainly directed the attention at women, and they are often focused on education (cf., Gansmo, 2004; Lagesen 2004). Women's attitudes and relationships to ICT have been studied empirically. It has been said that women's performances are measured against a norm that is set by men, and consequently women are considered to do computing in an inferior way and not up to standards (Corneliussen, 2003; Rasmussen & Håpnes, 1991). The difference is conceptualized in terms of men's more technical approach vs. women's more communicative approach; that is, men are deemed to be interested in and competent at technical matters whereas women are deemed to be interested in chatting and e-mail (Stuedahl, 1998). We may ask, however, whether this feature of "men as norm" does not actually refer to "real men," with varying user patterns, but rather to an abstract "ghost feature" of masculine gender symbolism.

Studies from working life have shown that when masculinity is symbolically linked to different technologies and to technical competence, it is the result of cultural practices (Cockburn, 1983, 1985; Faulkner, 2000; Lie, 1998; Mellström, 2003; Wajcman, 1991). The symbolic association of technology and masculinity is, in other words, not self-evident but must be produced and confirmed continually. This also tells us that gender symbolism is open to change, holding that matters do not "have" meaning but are accorded meaning by actors and within particular contexts (Geertz, 1973). My concern is how gender functions as a cultural distinction that literally "gives" meaning to technical artefacts and practices.

TECHNOLOGY AS CULTURE

A cultural studies approach to the knot of gender and ICT implies that not only gender but also technology is analyzed as a cultural phenomenon. Technology and culture are conceptualized as interwoven in mutual shaping processes. This mutual shaping can be studied in design and also during the cultural consumption of a new technology. In Norway, a user perspective and focus on cultural appropriation of technology have been prominent in gender and technology research (Berg, 1996; Lie & Sørensen, 1996). This is an approach following the traditions of social shaping or social construction of technology (Bijker & Law, 1992; MacKenzie & Wajcman, 1985;), the point being that a technical device could always have been otherwise. There is no technical necessity that leads to a certain end product, and culture is integrated, literally in-built, in the technical products. Moreover, the concepts of gender and ICT cannot be explored separately because they are intricately interwoven. This implies leaning on the metaphor of a seamless web of technology, culture, and society (Hughes, 1988) and on cyborgian and hybrid conceptualizations that blur the otherwise clear boundaries between nature-culture, both in the sense of sex-gender and human-technical (Haraway, 1991, 1997).

The connection of technology to masculinity has implied that tools are more easily identified as technologies when they belong to the masculine realm, whereas tools associated with women are more ambiguous and may be categorized otherwise, as with kitchenware or sewing-kits for instance. In this way, preconceptions regarding gender are constitutive for what is recognized as technology. Likewise, with technical competence as a characteristic of masculinity, technology has functioned as a device for sorting out gender. Although we recognize a variety of masculinities, meaning that there are many ways to be identified as "masculine", a close relationship to technology still remains one of them. However, whereas steel, cogs, and mechanical machinery produced masculine connotations related to muscles and strength, computers are more ambiguous. This ambiguity refers not only to the design of machinery but also to the varied social contexts of ICT use. Thus, the new ICTs could have meant a re- or de-gendering of technology, but the social processes taking place have directed ICTs towards traditionally masculine realms. One example is the linking of computer science to technical institutions; another is the production of software for "boys' games" (Cassell & Jenkins, 1998). But—it might have been otherwise. The rapid introduction of computers into a wide variety of contexts is contributing to the opposite effect of de-gendering ICTs.

GENDER AS "PRODUCER OF MEANING"

Here, gender is considered as cultural distinctions that are activated to literally "give" meaning to technical artefacts and practices related to them (and vice versa). The cultural categories of masculine and feminine may or may not be in accordance with what particular men and women look like and act like. Since the notions of femininity and masculinity are basic categories of distinction, though culturally specific, gender is a relevant category when technologies are designed, advertised, talked about—in other words, during all stages of a technology's "life cycle."

The design of technical artefacts is based upon imagined users and it may make a difference whether the projected users are imagined as men or women. The visions of designers are inscribed in the products, in the sense that "like a film script, technical objects define a framework of action together with the actors and the space in which they are supposed to act" (Akrich, 1992, p. 208). Such scripts can be deduced from the technical products, and differences that habitually are recognized as feminine and masculine may be identified in the design (Berg & Lie, 1995; Oudshoorn, Sætnan, & Lie, 2001; Rommes, 2002). Designing computer games, for instance, the imagined user is generally a young man, and designers emphasize that what they are after is "a good story"—but not reflecting on the combination of the two statements (Gansmo, Nordli, & Sørensen, forthcoming). Still, the combat heroines like Lara Croft are not only men's "perfect fantasy girl" but also an ambiguous mixture of male and female.

The design of technologies is, however, only one step in the process of its cultural construction. Even after a piece of technology has assumed a particular form, it still retains interpretive flexibility. Through the media, we get information on what this particular technology is meant to be, why it is important, and what it is useful for. We get other versions via product marketing and through education and information materials. These are ways in which technologies are domesticated within a particular cultural context. Users contribute to the process of domestication when they are adjusting technologies to their own needs and lifestyles; in other words "taming" them when bringing them home (Lie & Sørensen, 1996; Oudshoorn & Pinch, 2003). This is because technologies have to be enculturated in order to function, thus users must accord them meaning and fit them into their lives. Through domestication processes, new technologies are fashioned to users' daily lives and routines, which in turn are adjusted in relation to the new technologies. Domestication also involves the discussion and demonstration of technologies amongst users. An obvious example is how mobile telephones and PCs have become so visible in our daily lives, and how widely and enthusiastically the use of these objects is discussed and interpreted in everyday conversations.

In the cultural process of defining what ICT is, how it should be used, what ICT skills are, or in other words what "counts" as valuable knowledge and skills, gender functions as a cultural category in sorting things out. In this process of negotiating boundaries, gender is a marker that still functions to sort out high tech from low tech or no tech. The mobile phone, for instance, changed rapidly from a rather exclusive high-tech gadget to being for everyone. We might reason that the gender of the users affected the image of the artifact, as did the young age of the users, in the sense that when women and youngsters were identified as users, it became trivial. With PCs, chatting is often designated as a girlish activity, even if many boys, as well as adults, are active chatters; whereas gaming is held as "a boy thing", thus making girl gamers invisible (Nordli, 2003). In such ways, new technologies spur processes of boundary work and renegotiations of what is to be considered masculine and feminine.

The concepts applied and the examples given, serve to illustrate the point that neither technology nor gender should be taken for granted. Rather technologies should be studied as artefacts and types of knowledge that are shaped by cultural processes, not only while the technology is being developed and produced, but also by its subsequent use and reputation. Whether a particular technology is considered interesting and accessible or not, is dependent not only on how it is designed, but also on how it is presented to users and interpreted by them. At the same time, gender and gender relations are designed as relational to the different designs of technologies. So gender is not "given" in the sense that it consists of respectively male and female capacities and fields of interest that do or do not fit with technical artefacts and technical skills. What we need to study are processes of gendering (i.e. how gender transfers meaning to artefacts, practices, and places); the negotiations taking place when ICTs are introduced into new contexts or for new audiences; and the flexible interpretations of gender and technology in such cases.

To take an example: when young teenage girls together talk about computers as something nerdy (Håpnes & Rasmussen, 2003), they tell each other that this is something that we do not need to know anything about: we can ignore it, or, if we want to use it, we should under-communicate the use of it. Accordingly, ICT has a masculine label with negative connotations in a particular age group within which strong gender dichotomies prevail. Still, if a girl is good at it, she may be admired and not considered "nerdy" or masculine because of this interest. The nerd image is available but does not have to be used in a particular context. Moreover, such notions are flexible. Nerd may be used as a negative label, but at the same time some people like to use it, meaning to express that they actually spend a lot of time at computers and therefore possess wide expertise within the field. Likewise, the notion of the hacker has a double meaning, or maybe even triple: a "person without a life," super expert, or burglar/outcast. Again, several meanings are available as a repertoire one can draw upon. The nerd image is one, but that does not mean that the computer and its users are pinned down once and for all, as nerdy and only that, because there is always interpretative flexibility in cultural matters.

FUTURE PERSPECTIVES

One important change of gendered relations to ICTs is that women are increasingly participating as users. In this sense, ICTs are not linked to masculinity as an exclusive male domain. This trend also contributes to a de-mystification of the field—it is not only for nerdy insiders; rather, it is a technology for everybody. When it comes to developments within the ICT branch, however, this is still dominated by men, and we should therefore be aware of new "divisions within."

Lagesen (2003) has studied campaigns to attract more women students to computer science whereby one tries to redefine it as a "feminine subject" by stressing the aspect of communication. Lagesen points out that there may be a new trend not simply identifying ICT with masculinity, but towards a division whereby one tries to attract men by emphasizing the T, and detached from I&C, which are advertised as interesting for women.

We may be aware of such cases of re-gendering based on gender dichotomies. Still, I would like to draw attention to how cultural processes of gendering new matters also can take different and unexpected paths. There are a wide variety of possible cultural interpretations. Thus, it is not a good idea to take as a point of departure, that ICT is a masculine matter and ask how we can change that, but rather to seek out other issues from the wider cultural repertoire that can be associated with ICTs.

CONCLUSION

Is it possible to modify the cultural associations of gender and ICT?

Firstly, gender is more than differences between women and men. Gender is also a cultural distinction that provides us with categories that are applied to produce meaning. We literally use gender as a tool to identify ourselves, to identify people we relate to, but also to identify practices, events, and new artefacts. To "give" things gender is to put them into place, like when talking about computers as for instance nerdy/masculine or useful/feminine. We may instead talk about them as exciting and eventful and stress that they are multi-facetted—in other words, strive to attach to to them a wider repertoire of meaning that is not one-sidedly gendered.

Secondly, this leads to the question of change in relation to cultural matters. The problem with culture is that it is the very material we are thinking with.

Therefore, it is difficult to deliberately make a change and think differently. Still, there is some variety in the cultural images connected to ICT. What we should be aiming for is to utilize this variety and also to expand the repertoire. We may acknowledge and speak about ICT as a field that includes much more than male nerds and hackers. More attention should be directed at cases where women are active users and designers and where women use ICTs in unexpected ways. Even if these are not the "majority cases," they are important within a strategy for developing new perspectives on gender and ICT.

KEY TERMS

Boundary Work: Intentional and unintentional efforts to maintain gender divisions.

Domestication: The cultural appropriation of technology.

Gender Dichotomies: Feminine/femininity is defined in terms of being the opposite of masculine/masculinity and vice versa.

Gender Script: Gendered connotations are in-built in the design of a technology.

Gender Symbolism: Cultural associations of masculinity and femininity.

Key Symbol: A symbol that summarises main features of a certain time within a particular cultural context.

Script: Directions for use integrated within the design of a technology.

Cyber/Ecofeminism

Kaarina Kailo
Oulu University, Finland

INTRODUCTION

Cyber/ecofeminism is a holistic concept that I have coined and adopted to approach the burning issues of information technology, women's studies, and the women's movement in the age of globalization. It serves as an ethno- and gender-sensitive compass towards eco-social sustainability in an era where technology has an increasing impact on all aspects of life. In order to resist the Master identity that women, along with men, risk embracing, as they get plugged, downloaded, and wired into the digital world, one needs to introduce alternatives to the models of "compulsory heteronormativity," dichotomous and hierarchical sex/gender systems, as well as dysfunctional, exploitative animal/human relations. The dominant worldview is a world of "bits" and pieces—fragmented, atomistic, and hierarchical. It echoes in this like the hidden gender contract with its binary structure, segregation and splitting of male rationality of production and female care and emotional labor. Cyber/ecofeminism is my method and approach also for exploring which of the schools—cyberfeminism OR ecofeminism—promises more hope for a woman-friendly, ecologically, economically, socially, and culturally stable and sustainable future.

ECOFEMINISM

Françoise d'Eaubonne first invented and used the term ecofeminism in Le Féminisme ou la mort (1989). Ecofeminism has since then been associated with the premise that in global patriarchal practices, women, animals and nature share a subordinate and instrumental relationship to hegemonic, mainstream, and dominant men. The s/exploitive attitude is rooted in the Western epistemic tendency to separate feelings and care work as the domain of the subordinate class (particularly women) from reason and productive "rationality," the domain of men and mostly white elites. Denial of feeling-based knowledge and empathy enhances the ability to distance oneself from objects both of research and economic profit—a precondition for the kind of "rationality" that ignores the global ethics of care, belonging, and responsibility. Furthermore, underprivileged groups are subject to patterns, attitudes, and institutions of male domination and control that tend to also be gendered "feminine" as one of the means of that control in many parts of the world. Ecofeminists (for all their differences) see humans as integral components of the ecosystem, not separate or superior. Yet another key principle is the importance of non-hierarchical systems which follows from the holistic emphasis on interdependence and which leads to the complementarity and equal status of all parts of the ecosystem (Davies, 1988, p. 5; Merchant, 1992, pp. 76-78; Longenecker, 1997) argues that our notions of nature and ourselves change qualitatively if we imagine nature, not just humans, as subjects. It is much easier to exploit and abuse entities not perceived as having a soul, whatever "soul" or "spirit" evokes for modern people. A mechanistic interpretation of the surrounding cosmos is likely to lead to commodification of animals and vulnerable groups and serves ecologically short-term interests. Ancient pre-patriarchal gift economies in all their variety (Kailo, 2000, 2004a, 2005a, 2005b) were based on a worldview that was more conducive to mutually respectful and grateful human/animal relations because of the recognition of interspecies interdependency and the core value of life renewal rather than resource extraction: "In practical terms, hunter-gatherers would have to be the affluent societies par excellence. They are self-sufficient and thus genuinely autonomous. They have a stable interchange with their habitat, they use low-impact technologies—they work only a few hours a day, and give energies to social bonds, ceremony and art. Ecologists taking a lesson from Aboriginal cultures might discover how to devise low—demand, low-impact economies where sustainability and social equity can go together … (Salleh, l997, p. l30). Western industrial and patriarchal cultures have much to learn from "pan-indian" ecologically sustainable philosophies and worldviews in all their diversity although individual members of Native nations do not always practice what their cultural traditions promote.

CYBERFEMINISM

One of the perceived strengths of cyberfeminism is that it presents women with an optimistic alternative to theoretical positions that relegate women to the status of victims or glorified mothers within a context of a vilified omnipresent patriarchy. By focusing on women's abilities and contributions, cyberfeminist perspectives resist reproducing patriarchal constructions of women as technologically incompetent who cannot be wired into technology. Such views are influenced by post- modern theories, and owe much to the widely cited "Manifesto for Cyborgs" by Donna Haraway (1991). Haraway's article is an effort to displace traditional dualisms that associate women with nature and men with culture and technology. She does this through the cyborg seen as providing a theoretical way out of common western gender relations and representations. The cyborg is presented as breaking down the division between the artificial and the natural because this distinction is no longer practical in modern technological society. For Haraway, woman is the representation, no longer of marginality, otherness, objecthood, but of the middle ground between humans and machines, the virtual hybrid creatures that everyone is supposedly becoming: "A cyborg is … a hybrid of machine and organism, a creature of social reality as well as a creature of fiction" (Kemp, 1997, p. 480). One important route for reconstructing socialist-feminist politics is through theory and practice addressed to the social relations of science and technology, including crucially the systems of myth and meanings structuring our imaginations. She concludes the manifesto with her famous statement: "Although both are bound in the spiral dance, I would rather be a cyborg than a goddess" (Haraway in Kemp, 1997, p. 482). Perhaps the best-known ecofeminist, Vandana Shiva retorts to her in Stolen Harvests. The Hijacking of the Global Food Supply (2000, p. 75) "I would rather be a sacred cow than a mad cow," underscoring the optimism of cyberfeminists, and referring to the downside of cyberprogress—its links with economic greed and the devastating manipulations of unsustainable agribusiness. Sadie Plant also believes that the Internet is triggering most promising debates about gender, race, ethnicity, and class because its users have new possibilities now to act without revealing these variables of identity. Finally, women's condition as the other is becoming that of men: "To become the cyborg, to put on the seductive and dangerous cybernetic space like a garment, is to put on the female. If the male human is the only human, the female cyborg is the only cyborg" (Plant, in Kemp, 1997, p. 506). Plant shares in the optimism of a digital age where women so to speak come to their own as web spinners and spider women—arts needed to surf the waves of the digital age (Kailo, 2002a).

Gift circulating archaic societies honoring women, animals, and nature through ritual drama are some counter-patriarchal areas of ecofeminist research. Their "gift logic" valorizes meeting everyone's social needs and creating the conditions of basic abundance for all. Cyberfeminisms focus more on the ways in which humans and machines are intertwined and the opportunities opened up by women's integration into the technology-led information society. Although ecofeminists seek to extend an ethic of care and eco-social responsibility to boys and men, not glorifying girls and women as "the angels in the ecosystem" they have been accused of consolidating the stereotype of women's closeness to women and animals. Cyberfeminists have been more motivated to sever this connection. They have not always considered that ecofeminists' key point often is the failure of men to embrace the eco-social values labeled as "feminine." They have been delegated as the duty and realm primarily of women—something feminists feel must be changed if the brave new information society is to become a just and healthy world for all.

COMBINING ECOFEMINISM AND CYBERFEMINISM

On the basis of my research regarding the eco-social impact of neo-liberal globalization, I have grown more skeptical of the promise presented by the cyber revolution for gender equality. I have had opportunities to participate at the events of an international alliance—Feminists for the Gift Economy—and to share views and strategies on ways of exposing, questioning, and transforming the competitive and short-sighted neo-liberal agenda. Among others, Vandana Shiva (1997, 2000)and Zillah Eisenstein (1998) have produced research and counter-patriarchal perspectives on global values that have a sobering effect on any excessive cyberoptimism as regards improvements to women's local/global status. Eisenstein (1998) cites numerous statistics and studies, which reveal the darker side of digital culture. Not only has the great advance in information technology and communications led to increasing gender-based injustices, but it has created the world-wide-wedge across many divisions, the leading Western industrialized countries and the developing countries in Africa and Asia, the intersections of gender, class, geography, age, ability, and religion being additional factors to consider. Under neo-liberal governments, decision-makers are providing businesses with unprecedented financial support (tax-payer money), which they spend on technological innovations that reduce the need for manpower, thus enhancing unemployment, automatization and accumulation of profit and power for wealthy corporations. Statistics and research (e.g., Ngan-Ling, 2003; Wichterich, 1998) reveal that across the developed and overexploited world, women serve as the class of cheap and flexible labour that allows the male-dominated fields to enhance their competitive edge—by outsourcing costs and employees to countries with weaker labour and environmental regulations. Women benefit from globalization thanks to the numerous new labour opportunities—however, they are often in sweatshops and involve miserable working conditions. Women's domestic and work-life flexibilities (low-paid or unpaid care work) are as surplus labor a kind of forced gift to the capitalist market economy. We must not forget what has always accompanied technological advances: instead of narrowing, they have tended to deepen the gap between the haves and have-nots, most of whom are women. Information society is also giving women—particularly elderly and poor women of the developing world—the shorter end of the (joy)stick. Eisenstein lists the amount of tax breaks given to corporations and wealthy individuals in l996 as US 440 billion, more than seventeen times the combined cost of state and federal spending on AFDC (Aid to Families with Dependent Children) (Eisenstein, l998, p. 62).

Technology and information society benefit greatly from women's ways of building community. I propose cyber/ecofeminism as a marriage of the two feminist schools (eco- and cyberfeminism) and as a self-reflexive method/worldview seeking to ensure that as feminists, we do not reproduce the hierarchical dualisms and controlling stance of the master imaginary. To be an ecofeminist need not, and often does not mean being technophobic, deluded or bent on mytho-pathetic reverse sexisms. It is not the technologies that alone wreak havoc anymore than it is nature that guarantees bliss and organic autonomy. It is the attitudes, ethos and values that humans bring to both that alone guarantee integrated, affective, and solidarity-oriented ways of being in the world, of sustaining the future in ecologically, culturally and ethno-politically sound ways.

Ecofeminist interest in peaceful, just societies and "matriarchal values" is not deluded and irrational as cyberfeminists have assumed. Archaic cultures contain much of the ecological and communal values that are needed in order to transform the dysfunctional profit-focused world of today. They provide blueprints for denaturalizing today's dominant assumptions according to which self-interest and greed, as well as the competitive impulse are the best guarantors of collective prosperity, economic growth, and social wellness. I call the totality of counter-hegemonic, need rather than profit-oriented strategies, approaches, ways of relating and circulating care the Gift Imaginary (Kailo 2004a, 2005a). One of its Internet applications could be the free software and other non-market-oriented gifts meant to make information technology—its material and immaterial innovations—accessible to all. We have to make sure that cyberpower is distributed and shared in an equitable manner between all of the "stakeholders" of the earth. Alternative non-dualistic imagery—adapted to modern times rather than romanticized—may well be found in prehistoric societies, but also in our current eco-social imaginary. Still, our modern imaginations are colonized and imbued with ecologically questionable models of consumerism and a media-run rat race or musical chairs. Gift and Give back economies provide a mind-altering example of a system based on global care, one based on circulating common gifts to those in need, and not only as part of (asymmetrical) exchange (Vaughan, l997, 2004). We need them to counter the unholy alliance of concentrated multinational power conglomerates and technological innovations supporting citizen surveillance and militarism done often at the expense of an ecologically and socially healthy planet. We also need counter-hegemonic representations of gender and gender relations that might contribute to men also identifying more with other-oriented gift circulation and solidarity work. As more and more women enter the male-dominated fields of IT and economics with their often competitive and ego-oriented market values, more of the care work needs to be shared equally by men and women. Women must no longer be made the exclusive embodiments and providers of emotional and domestic labor or those meeting the needs of children, the sick, and elderly. As women are becoming more like men, men must become more like women. Both need to adopt a healthy and ethical relationship with the "other," including the environment, as the precondition of an ecologically and societally sustainable future.

The widely-spread cross-cultural stories of women finding refuge from patriarchy in the bosom of nature with Bear are examples of archaic representations of human/animal relations that defy the hierarchical, dualistic tenets of the master imaginary. As transmitters of ecospiritual principles and embodiments of inner power, they are counter-mythologies that contrast with the dominant anthropocentric heroic myths. In these gynocentric myths women are are not defined in relation to male desire, as currency of exchange and exploitation. Women also need images of their power and multidimensional human possibilities beyond the whore/Madonna dualism or the gender equality discourse aimed at merely turning women into "honorary males." The woman/bear stories displace and challenge many of the taken-for-granted dualisms of Western identity: human-animal, dead-alive, male-female. From today's perspective, such alliances linked with "primitive" eco-socially sustainable economics mixed with spiritual beliefs are transgressive of the strict gender scripts and other norms of sex, culture, nature, and species (Kailo 2001a, 2002b, 2006a). Neither a reversal of Western dualisms, nor a mystical marriage of opposites, these stories are examples of a representation of human social organization as an eco-social pact that seeks to ensure the reproduction of nature's cycles, of proper human-human and human-animal relations. It is worth recuperating the images that present alternatives to the super-segregated gender roles resurrected by WIRED and other elite male magazines. As we seek to resist the politics of cyberporn and violence, we need representations of hybridity as a symbol of intersubjectivity and equality, not as a mere postmodern game of gender performance in a world of unchanged power relations. Beyond the marriage of machinery, technology, and gender, we need role models of ethical belonging and examples of peaceful societies to show that aggression and fierce other-denigrating and trampling competitiveness are not a universal norm (Miedzian, l991). We need also cybergoddesses with a difference: not as decorative and sexy objects, consumerist gifts for the male gaze, but as tokens of another scene, also of and for women of colour, poor women, women and men out to nurture the eco-social sustainable future of each other, and of the planet.

CONCLUSION

Cyber/ecofeminism as the combined appropriation of modern technology and ancient eco-social ethics of belonging is thus a creative paradox and a provocative means of riding the rapids of digital modernity, while ensuring the necessary politicization of the latest cyberfeminist wave. Technology does not create equality—power-sharing and a more fair redistribution of the world's resources in the concrete realm of politics and decision-making alone can accomplish that. Cyberspace is yet another male bastion, wired to keep feminists and other less powerful groups out. While I thus advocate hactivism—using cyberspace ethically, creatively and efficiently for networking in the name of global justice—I also advocate adopting the worldview based on the gift logic beyond the utilitarian master imaginary. Cyber/ecofeminism is a dance across the tight rope wires of patriarchal technology and the nature that supports them, a juggling act to challenge in-vitro-feminism. We do not benefit from virtual justice or virtual equality. We need concrete politics of affinity, eco-social justice and balance, here-and-now. The group—Feminists for a Gift Economy—sharing views on a Gross Nurturing Product, not the woman-exclusive GNP—is just one international pro-democracy alliance that is seeking to create another possible world—based on fair trade, fair technology, and equal opportunities for radically transforming the masculated (Vaughan, l997, 2004) world.

These are the values that guide me in my ongoing research on the gender impact of neo-liberal globalization and information society.

AUTHOR'S NOTE

This article was presented in slightly different form at Gender and Power in the New Europe conference (Kailo 2003b).

Prof. Kaarina Kailo, PhD, Oulu University, Women's Studies, Gender Equality and Sustainable Development Consultant, & Expert of the Women, Industry and Technology EU/Equal Project; Responsible for the WomenIT Equality Issues Pilot and for training the Project Partners at Oulu University.

KEY TERMS

Cyber/Ecofeminism: A holistic method and approach for exploring the positive and progressive ways in which two feminist trends—cyber and ecofeminism—can be combined to enhance an eco-social sustainable future with equality and collective wellness as its pivot. Cyber/ecofeminism is proposed as a third term and concept to bridge the best of both schools of thought which are often perceived as each other's opposites (Kailo, 2003b).

Cyborg: "A cyborg is a cybernetic organism, a hybrid of machine and organism, a creature of social reality as well as a creature of fiction" (Haraway, 1991).

Ecofeminism: Associated with the premise that in global patriarchal practices, women, animals, and nature share a subordinate and instrumental relationship to hegemonic, mainstream and dominant men. The diversity among ecofeminists is as desirable and intentional as the diversity they promote and advance as a rewarding value in the biosphere and among human cultures themselves (D'Eaubonne, 1980).

Design and Women's Expectations of WWW Experience

Noemi Maria Sadowska
Regents Business School London, UK

INTRODUCTION

Development of the World Wide Web (WWW) prompted a flurry of research investigating women's participation in the creation, production, and use of online technologies. Initial studies focused on trends in female users' participation rather than investigating the role of design in these processes (Pattanaik, 1999). Web design practice was rarely a focus. This article presents findings from my PhD research, which applies feminist and design theory to critique Web design. Focusing on a commercial UK based women's portal, BEME.com, I examine the value of Web design practice to female users and their expectations of online interaction. I describe the type of experience BEME.com intended for its female users, as outlined by the design team during interviews. Interviews with the production team were conducted two years after the design was completed, making them reflective in nature. Alongside interviews with the intended target audience, the aim is to highlight disparities between design intentions and female users' expectations.

BACKGROUND

Encouraging the discipline to review its position on gender and design, Buckley (1989) argued that design is implicated in maintaining patriarchal power relations. She warns that "female stereotypes [materialised in design practice] delineate certain modes of behaviour as being appropriate for women." (p. 252) Similarly, Whiteley, (1993) says "market-led design" represents … women in a sexist way, and … disregards women as end-users" (p. 137). Buckley (1989) observes that "[t]hese stereotypes have had enormous impact on the physical spaces "… which women occupy their occupations, and their relationship with design" (p. 252). On the other hand, Forty (1986) maintains that design practice offers a paradox where design practitioners are in charge of what they do and yet they are also willing or unwitting agents of ideology. Julier (2000) observes design practice role in defining consumption, making it active and passive, meaningful and meaningless all at the same time. He highlights design practice involvement in "… refining and controlling … patterns of meaning which pass from production to consumption" (p. 64).

Matlow (1999) advocates that new technologies are symptomatic of a paradigm shift from "modernist graphic design towards [a] fragmented postmodern approach." (in Warwick, 1999, p. 15); a shift illustrated by "… movement away from rigid structures and principles to the transparent and ephemeral which exists for the most part within virtual dimensions." (Warwick, 1999, p. 15) Matlow (1999) believes that this shift in relation to gender "… can illuminate professional and individual [design] practice" (in Warwick, 1999, p. 15). Thus, I argue, the relationship between gender and design within the context of the WWW is at a crossroads. On one hand, research has highlighted the conservative gendered approach to design for the WWW (Martinson, Schwartz, & Vaughan, 2002). On the other hand, the opportunity is ripe to investigate alternative ways to tackle gender (Spilker & Sørensen, 2000). There is a particular need to "… [assess] the deliberate, accidental, and alternative technological decisions and design-processes which, when implemented, form the interface between the network and its users" seeking "… to offer more complex, more problematized findings" (Silver, 2000, p. 24-25). Such an approach allows this study to go beyond mere description of the WWW and investigate the relationship between gender and design practice within an online context.

The BEME.com case study provides the opportunity to examine a portal developed directly from the women's magazine publishing tradition. A product of publishing company IPC Media (UK), which specialises in what are referred to as traditional women's magazines (including Marie Claire and Woman's Own). Its development in 1999 responds to an online industries boom at the end of the 1990s. The life-span of BEME.com—with its launch in 2000 and its closure only a year later—partially reflects the fortunes of Internet businesses more generally which, following initial commercialisation is threatened by economic collapse in 2001. The way in which the site design responds to these circumstances is revealing of the relationship between design processes, gender ideologies, and the commercial context.

The original design of BEME.com is slick, uncluttered, and thematically structured with a vertical layout, distinguishing it from other women's portals. The content and editorially driven BEME.com "brand" is given priority over an e-commerce led strategy. However, at the beginning of 2001, limited commercial success triggers a redesign strengthening its connection to paper magazines and to other women's portals. When this redesign does not generate sufficient advertising revenue and the site closed in August 2001. Its demise is attributed to its relatively late emergence in the dot-com boom as well as to the question of whether an editorially driven niche portal is the best way to attract female users. That notwithstanding, BEME.com is a site where ideologies, history and tradition materialise in the design process and artefact. Disparities between the intentions of the design team for the site and expectations of female users alert us to the issues affecting design attempting to reconcile a critical agenda with both gender structures and commercial imperatives.

INTENTIONS OF DESIGN TEAM

The intentions of the site, as expressed by the design team, fall into four main categories: corporate, visual, emotional, and women-focused intentions.

Corporate Intentions

Corporate Intentions relate to the public side of BEME.com—the aim to construct a unique brand. The male brand designer recalled that the best way to respond to today's online female user was to recognise her multifaceted identity. Hence, the intended "BE ME" experience was driven by the notion of "AND" or "BOTH" rather than an approach where readers subscribe to "ONE" ideal like the "Cosmo girl" or the "ELLE woman."

Nonetheless, corporate intentions were based on interpretations of what was already available for female users and what was on offer was based on interpretations of existing gender structures and stereotypes (Beetham, 1996). However, BEME.com did not put forward a straightforward interpretation of gender but offered a contradictory mixture of approaches. For example, the female editorial/creative director describes female users as both "…pathetic and clever, funny and serious, gorgeous and beastly, silly and thoughtful, glamorous and insecure" (D-CP1, l. 18-24). In her interview, she insisted that BEME.com's design was based on non-stereotypical representations of female users. While one could argue that her mention of "pathetic *and* clever, funny *and* serious ..." is anti-stereotypical. A radical feminist analysis also criticises the notion of "and" or "both", insofar as women are not only *allowed* but are *expected* to be both pathetic and clever, assertive, and submissive, women, mothers, wives *and* lovers; in other words, whatever patriarchy demands. Therefore, an attempt to absorb a feminist critique of gender often resulted in its dilution (Winship, 2002, p. 37). My research suggests that BEME.com's corporate intentions perpetuated the contradictory values (Ballaster, Beetham, Frazer, & Hebron, 1991) that have for 200 years secured commercial profit for the women's magazine publishing industry.

Visual Intentions

For BEME.com to sustain interest, the site needed to bring together interesting and relevant content, which meant a complex multi-level portal design. The male brand designer believed that this complexity required it to be intuitive and simple, with enjoyable layouts made relevant to female users by focusing on their daily lives (examples of which are unfortunately unavailable due to the site's closure). The visual language aimed to offer new, snappy, and easily accessible experiences with expandable content. Technological innovations of the WWW demanded that BEME.com be experienced through active participation rather then just observation. BEME.com's emphasis on one-to-one communication aimed to mirror the individuality of female users. However, these empowering ideas were undermined by ambiguous messages regarding gender structures. In descriptions offered by the designers, reference was made to employing alternative graphic norms, which, for their novelty in design for women, paradoxically revealed, the stereotypical norms informing BEME.com's design. Graphic norms that were described as inappropriate also indicate the particular gender ideology informing the design process. For example, the male brand designer observed, "[the] type that we used [for BEME.com logo] is what they use for motorway signs in the United States. So it's … quite bold and in your face ... which you wouldn't normally associate with … women's ... stuff." (I-PT4, l. 191-195) He goes on to state, "... [the letters used for the logo] really work .. they don't look hard and they don't look … aggressive. ... it just really works because it's bold and it's confident" (I-PT4, l. 198-200). An underlying gendered approach was criticised by the female senior producer. Not certain that women's portals should necessarily be feminist, she pointed out a lack of female designers on the production team, adding "… the actual concepting and design was not female at all. … as far as the [design] process goes, it's the same." (I-PT5, l. 285-287) This suggests that in her view, more women in decision-making positions would have resulted in a *different*, if not feminist approach. As Rommes (2002) argues, it is not enough to have female members as part of the production team. Gender structures affecting the design process have to be addressed.

Emotional Intentions

Emotional Intentions informed the design team's efforts to inspire brand loyalty. The male design manager/designer believed that loyalty would result from offering personalised experiences. The production team insisted that interaction with the site had to be enjoyable and only then would female users continue to visit and endorse the site.

Women-Focused Intentions

Women-Focused Intentions addressed the specificity of the target audience. The female senior producer associated women-focused intentions with the notion of an online female community. Women-focused intentions meant recognising the value of the target audience as intelligent, complete individuals. She endorsed a strategy "… to get women talking about BEME and talking to each other … to keep them there and to keep them in the community aspects …" (I-PT5, l. 346-349). She was the only member of the team who questioned female online users' association with gendered assumptions.

EXPECTATIONS OF TARGETED FEMALE USERS

Hawthorne and Klein (1999) emphasise the importance of women's participation in the development and regulation of Internet technologies. As Reitsma, Reeve, and de Regt (2000) argue, the commercial world conceives of women's involvement in terms of consumption and spending, the research has revealed female users' engagement with the WWW to be far more complex.

A yearly market survey monitoring the British population's response to the Internet indicates that users see the WWW primarily as a resource supporting their e-mail, education, research, and/or information seeking (which?online, 2002). Female users interviewed in my research were mainly concerned with its practical capabilities, as a tool where "purpose" and "access" were important. The "visual" factor was not of great value to the female users; unless it infringed on access, they expressed little interest in changing online content design. They saw BEME.com as a finished design outcome without possibility of adjustment, an irony in light of the fact that it is easier to alter online than print media.

How female participants saw themselves as online users was associated with the "emotion" factor; the types of experiences individual users have had and the construction of their identities. At the present time, being knowledgeable about new technologies is just as important as other aspects of identity construction: "... the WWW is now seen more than ever as a fundamental part of 21st century living" (which?online, 2002). Therefore, "keeping up with progress" was another factor informing female participants' constructions of themselves and it was this belief that linked female users' purposeful application of the WWW to their understanding of themselves as online users. Of particular interest was female users' lack of concern about how they might be perceived by others as consumers of the WWW. My research suggests that female users saw themselves as part of a social collective, offline and online, neither of which infringed on their strong sense of individuality.

Although BEME.com claimed to promote individualised experience, it classified users by their gender. Feminist scholars have problematised commercial application of the WWW where female users are seen as a gendered niche market addressed in one voice (Crow, 1997; Paasonen, 2002). Similarly, the interviewed female users did not see themselves defined only by gender. They felt they knew what they wanted from the WWW and that others either shared those notions or were aware of them. However, this was not reflected in the "women-focused" understanding promoted by the female senior producer of BEME.com. Rather, the interviewed female users echoed the female editorial/creative director who endorsed the idea of recognising women as individuals with a strong sense of self and consumer choice.

In summary, BEME.com generated a set of social interactions embedded within the site layout where systems of power and resistance were negotiated. Although the design team were in a position of power, they did not actively question "historical continuities" in terms of gender structures, perhaps signalling what Foucault referred to as "force relations," where "power relations have become so entrenched that they can seem entirely one-sided and unchangeable" (in Gauntlett, 2002, 1.118). In the context of BEME.com, power relations derive from the commercial tradition of the women's magazine publishing industry that has relied on the continuity of gender structures to generate profit. I argue that there is more to women's use of commercial online spaces than their gender. Female users operate within a highly complex world, of which the Internet is just a part.

FUTURE TRENDS

Design knowledge and experience is based on evaluation of existing and conceivable outcomes, just as consumer surveys are based on reactions to current rather than future designs. This leads to a built-in conservatism in terms of influencing or responding to, consumers. Recent studies of inclusion strategies (Faulkner, Sørensen, Gansmø, Rommes, Pitt, Lagesen Berg, et al., 2004; Rommes, 2002; Spilker & Sørensen, 2000) are incomplete without conceiving of design processes as material outcomes of a social, cultural, political and economic milieu. Faulker et al. (2004) argue, "[t]he market has not generally proved a very innovative mechanism for improving gender inclusion in the information society …" (p. 3). Further cross-disciplinary research into the relationship between design, gender and the WWW is needed to address disparity between the gendered production of online design outcomes and what female users perceive as useful.

Designers need to engage with new paradigms prompting a shift from "product design" to time-based "service design." Here, interactivity could become a key driving force. Burnett and Marshall (2003) argue that online interactivity encourages users to engage in a different kind of literacy encompassing simultaneous reception and production. Understanding consumers simultaneously as producers should have a profound impact on the role design plays in constructing online experiences for female users in the future.

CONCLUSION

An investigation of commercial sites like BEME.com provides important insight into the ways Web design practice attempts to reconcile a critical agenda with gender structures. It illuminates female users' tendency to disassociate with identities constructed in gendered niche marketing. However, the media landscape is changing, where "… the popular … media now promote … a new rhetoric of freedom and independence for young women …" (McRobbie, 1999, p. 11). Therefore, a question arises as to how radical the design agenda can become whilst continuing to operate within a commercial context. Has BEME.com become an example of the need for far more radical design in this commercial sector? Whether BEME.com's closure is attributed to either a strategy of "silence" (Baudrillard, 1985) or merely a lack of interest, it is clear from my research that current commercial imperatives are deeply implicated in gendered structures. BEME.com's original design did not meet these commercial demands and yet neither did its redesign, which, one could argue, "sold out" to commercial priorities. Just as women are clearly not passive consumers, design practitioners in a commercial environment have both the opportunity and a responsibility to affect and *effect* changes to a gendered status quo.

KEY TERMS

Design Practice: It embodies design practitioners' ability to create something new within preexisting conditions and imbue it with meaning decoded and understood by others. It is positioned at a crossroads where the ongoing creation of new solutions meets the need to maintain the existing status quo.

Feminism: Feminism "… acknowledges that women form a group among many in a multicultural society, with different tastes, needs, values, and orders of priority because of the roles they play, the type of jobs they do and the position in society they occupy through the accident of their birth. In this context, feminism is a political position which seeks changes in the interest of women" (Attfield, 1989, p. 200).

Interactivity: Refers to interactions similar to interpersonal communications, where structure of technology, communication context and user perception play an important role. (Kiousis, 2002, p. 372) Interactivity is situated within social, cultural, political, and economic context and sets apart online communication from other media like print, film, or animation.

Patriarchy: Understood as "…a Web of psychosocial relationships which institute a socially significant difference on the axis of sex, which is so deeply located in our very sense of lived, sexual identity that it appears to us as natural and unalterable." (Pollock, 1982, p. 10)

Portal: An online "gateway" considered as a starting point for users when connecting to the Internet. It can act as a point of reference in how to view and organise the information obtained online. There are portals that are general in their services or niche portals that specialise in specific interests.

Service Design: Service design represents design of intangible experiences, happening over time, and reaching people through many different tangibles such as advertising, PC interfaces, retail shops, call centres, and customer representatives. (live|work studio ltd., 2004)

Women's Magazine Publishing Industry: Commercial practice focused on publishing women's periodicals often associated with traditional values, and referred to as "glossy magazines." With the introduction of the Internet, the term has also been used to describe commercial online sites specifically targeting female audiences that subscribe to similar values and practices.

D

A Developing Country Perspective on Women's ICT Adoption

Annemijn van Gorp
The Pennsylvania State University, USA

INTRODUCTION

The explosive growth of information and communication technologies has become a worldwide phenomenon. However, merely countries in the West as well as a growing number of countries in Southeast Asia have become largely connected, whereas the majority of people in the developing world have not yet been able to take advantage of the new opportunities ICTs provide. Especially in developing countries, Internet access remains a luxury of small groups of elites, and even the use of old-fashioned telephone lines remains a luxury for a minority of the people. While the lack of availability of technological infrastructure looms large, the basic lack of education and technical skills impedes further potential for the large-scale adoption of ICTs (e.g., Cawkell, 2001).

The opportunities of ICTs are commonly discussed in terms of business opportunities—as a means to enhance economic competitive position at either the level of the firm, region, or nation. This entails a narrow scope. ICTs have the ability to enhance the quality of life in a broader sense as they have the potential to improve interpersonal communication, and moreover could allow for the social and political empowerment of ordinary people (e.g., Hafkin & Taggart, 2001). This implies a direct downside as well: Those people with significant access to ICTs and thus information resources are in a position to increase their control over social, political, and economic arenas, making nonusers further marginalized and excluded from not only economic life, but social and political life as well (e.g., Cawkell, 2001; Morales-Gomez & Melesse, 1998).

In this regard, Forestier, Grace, and Kenny (2002) have found that, historically, telecommunications rollout has actually increased inequality because only the wealthy can afford implementation and use. Nevertheless, the authors also find that both telephony and Internet access could be a force for the convergence of incomes and widespread improvements in quality of life in the future, as costs of ICTs are decreasing and hence access becomes a possibility for the poor as well. Nevertheless, in the case of the Internet, the absence of policy initiatives with regard to access coverage, training, and content development aimed specifically at the poor make it likely that this new technology will also be a force for further income divergence like telecommunications rollout has traditionally been (Forestier et al., 2002).

BACKGROUND

While more awareness is being raised concerning this digital divide, problems are often expressed in the number of Internet connections or the extent of ICT deployment at the country level, which does not provide us with adequate insight into the factors within such countries leading up to the challenges (e.g., James, 2005). A variety of specific factors influencing the digital divide and access to ICTs in developing countries needs significant in-depth exploration if we want to change the situation.

For example, it is well known that most countries face a significant urban-rural digital divide: In urban areas and especially major cities in developing countries, typically a significant number of phone lines is deployed as well as means for access to the Internet, but rural areas often lack basic infrastructure. Nevertheless, while the case has been made that improved telecommunications or access to ICTs will permit improved cost benefits for rural economic activity, these discussions often neglect the impact that urban-rural connectivity could have on local trading in rural areas and the possible danger for the destruction of relatively self-contained rural economies (Samarajiva & Shields, 1990). Thus, while ICT may provide great benefits, its introduction may also induce further dependencies of the poor on the wealthy.

Alongside this rural-urban divide, we find that among the least connected in the world are women in developing countries, in particular those women living in rural areas. Moreover, the majority of women are located in rural areas, situating them in the deepest part of the digital divide. Problems for the integration of these populations in the information era depend not only on the lack of infrastructures and the high costs of ICT deployment, but even more so on illiteracy, unfamiliarity with the dominant English language in Internet content, unfamiliarity with the use of ICTs, and the lack of availability of software and content suitable for use. People's information needs in developing countries may be very different from people in Western countries, depending on social and cultural (work and household) practices.

While these issues provide a major challenge for appropriate ICT introduction and uptake, James (2005) shows that it seems often forgotten that even though individual access is very limited in developing countries, a remarkable number of local innovations have been made available to some 10 million people within developing countries. While many of these people are illiterate, have limited skills, and live in rural areas, significant progress is being made. Therefore, James (2005) argues that national governments and foreign donors need to pay less attention to providing individual access facilities and need to focus more explicitly on ways to enhance indigenous rural innovation systems devoted to finding relevant and cost-effective applications of the Internet.

From this it follows that social and cultural context provide the backdrop against which ICT implementation for any particular group of people, and thus indeed for women too, is appropriated. This means that while women's adoption of ICTs would provide a means for sociocultural empowerment, at the same time we need to acknowledge that these sociocultural issues, and thus women's position and role in society, will provide constraints for the adoption of new technologies. Thus, we need to understand the very specifics of women's lives in their particular communities in order to be able to change the situation in an appropriate manner.

In order to illustrate some opportunities and constraints for implementing ICTs in line with women's social and cultural context, a short overview of women's lives in Bangladesh will be provided along with background information on current ICT implementations.

THE CASE OF BANGLADESH: WOMEN'S USE OF VILLAGE PHONES

Bangladesh is one of the least developed countries in the world,[1] facing very high poverty levels. While it is one of the most fertile countries on earth, annually about one third of the country gets flooded during the monsoon season. The country has a high population density and is currently inhabited by about 144 million people, of which nearly two thirds are employed in the agricultural sector.[2]

The use of ICTs in Bangladesh is rapidly increasing, and government initiatives and policies on ICT have been in place for already over 20 years.[3] However, as explained by Bhuiyan (2002), while ICTs were introduced a long time ago, the majority of computer installations currently are significantly underutilized; moreover, the functions for which they are being used remain limited, partly due to the lack of people with computer qualifications, skills, and experience. The additional inadequate local market for hardware and software development makes installations vulnerable. Also, the lack of understanding at senior levels of the potential of these already implemented ICTs hampers further appropriate uptake. Finally, the out-of-date telephone systems and the erratic power supplies restrict further development of ICT potential (Bhuiyan, 2002). Nevertheless, increased deployment of ICTs in Bangladesh has been argued to be able to stimulate socioeconomic growth: It could allow not only for market growth and the creation of an efficiency-oriented economy or administrative restructuring, but for community development, personal growth and self-reliance, and the integration of women into the mainstream of development planning as well (Bhuiyan, 2002).

While these typical ICT deployments have provided opportunities only for a small part of the population, especially for the higher educated workforce, in the last few years the upcoming of cellular technology has provided a great leap forward for Bangladesh. Grameen Phone, under the umbrella of Grameen Bank, has introduced the Village Phone Program. The Village Phone Program focuses on rural cellular communication connectivity, especially for the poor population. As this short overview will show, the program has increased connectivity and to some extent has enhanced the empowerment of women. Before turning to some of the specifics of this program, some background will be provided on women's role in Bangladeshi society.

Women's Role in Society

Like in many other developing countries, women in Bangladesh are severely restricted in mobility because of their traditional roles in the household.[4] Their activity space is closely tied to the neighborhood, while public roads and markets are primarily male spaces where women may only go in appropriate company as well as appropriate dress (Paul, 1992). Nevertheless, female space in rural Bangladesh has been expanding in recent years as a consequence of socioeconomic changes related to increasing landlessness and impoverishment (Paul, 1992). Yet, the expansion of female space nevertheless is not uniform across socioeconomic classes.

While more women now seek access to the labor market, which has long been dominated by males, and generally speaking women constitute an important part of the labor force in Bangladesh, it is mainly in the bigger cities where one will see women working in income-generating jobs such as in factories. A research project taking place in the summer and fall of 2001 in which the author was engaged[5] found that in the rural areas, women's roles are more traditional: Women work very hard from early morning until evening, but typically in nonwage jobs within the family sphere where they take care of household matters (getting water, cooking, cleaning, taking care of children), and in addition also often engage in work related to the family practice such as, for example, drying rice.

Furthermore, it was noticed that in Hindu settlements (North Jalirpar, Gopalganj), women could walk around rather freely, but they would mainly stay within their clan (family) settlement, walking about 250 meters to collect water, at the most. Women would usually only leave town to visit family, guided by other family members. Males do the grocery shopping, visit markets outside of town, sell their own produce, and so forth. In Muslim villages in the Sonargaon area (a peri-urban area close to Dhaka), women's mobility seemed even more bound to their own family settlement.

With these restricted roles, it is not surprising that the majority of women in Bangladesh are illiterate. Girls often leave school before they reach the high-school level because parents do not have enough financial means. Moreover, one of the major social issues is parents trying to have their daughters married at a very young age so that their husbands can provide further financial support. Thus, girls at a very young age are prepared and taught matters of taking care of the household rather than learning at school, keeping illiteracy numbers high even though awareness of the positive impact of education is evident.

These social spheres and related roles for women obviously have their effect on women's engagement in the world beyond their family settlement. With women typically spending their days within their family settlement, social, economic, and political empowerment are likely to remain limited. Nevertheless, increasing possibilities for communication in Bangladesh have the potential to slowly bring some change. Women's restricted mobility implies limited possibilities for accessing ICTs far away from home, and moreover, illiteracy rules out the use of advanced Internet technologies. However, Grameen Bank's Village Phone Program provides services considerate of these limitations, allowing for enhanced communication possibilities and hence more empowerment.

Grameen's Village Phone Program

Grameen Bank has a history in providing services for the poor, of which its microcredit program has become a world-renowned model for poverty alleviation. Grameen Bank targets women by providing them with small loans in order to stimulate socioeconomic growth. Grameen Bank moreover often integrates microcredit programs with women's discussion groups in order to disseminate information on health issues; to provide literacy training and skills development; to educate on family planning and political consciousness, and so forth (Richardson, Ramirez, & Haq, 2000). This program has been imitated extensively by other non-governmental organizations (NGOs) throughout the country. However, the extent to which microcredit programs have a positive impact on women's empowerment is scrutinized. Both positive and negative stories have been heard. Some programs demand women, after saving some money, to buy goods from the organization originally providing the credit and thus increase women's dependency as opposed to independency. Other microcredit programs, however, have been reported to have allowed for significant empowerment (e.g., Amin, St. Pierre, Ahmed, & Haq, 2001).

Grameen Bank has expanded its development services with Grameen Phone, introducing the Village Phone Program. In this program, Grameen Bank leases cellular phones (village phones) to successful microcredit members. Village members can go to the village-phone owner to make phone calls, and at the same time owners bring the phone to village members when they receive a call. Village-phone operators are typically women, as 95% of Grameen Bank's members are women because of its microcredit program (Richardson et al., 2000). While the owners are generally rather poor because of their involvement with Grameen Bank's microcredit program, these people at the same time have been reported to do relatively well as they are leaders in terms of literacy, child immunization rates, and the use of safe drinking water and sanitary latrines (Richardson, et al., 2000).

The Village Phone Program has been reported to have increased socioeconomic benefits for its users, foremost to phone owners but also to the larger community. First, substantial revenues are earned through the phone, and additionally, female owners seem to gain more decision-making power within the household by being part of this revenue-generating activity (Richardson et al., 2000). While it has been reported that phones are often in the husband's control during the day (Richardson et al., 2000), female owners' degree of mobility in and around the village has significantly increased because incoming phone calls sometimes make it necessary for the phone owners to take the phone to village members. Bayes (2001) furthermore finds that women's knowledge was increased because of overhearing other people's phone calls. For example, they have been reported to learn about the names of places where phone calls originated and about new markets.

With respect to benefits to the larger community, we see, for example, that other women in the village come to the phone owner to make phone calls, which increases their mobility within the village. Mobility and social contact outside the village are also enhanced: Families visiting relatives outside the village contact them by phone and inform them of the time of arrival, thereby reducing family tensions and conflict and strengthening family relations (Bayes, 2001). Finally, beyond these direct benefits to the people involved in the program, an extra benefit comes to the fore in the actual involvement of poor people in telecommunications supply: They are becoming actual managers of new technologies and hence are able to use and provide technology according to their specific culturally and socially appropriate needs.

CONCLUSION

The background discussion indicated that while significant efforts are being put forward to provide more attention to the potential benefits of ICT deployment for socioeconomic development in developing countries, mainstream discussions typically remain at an abstract level. More than often, the specific needs of particular groups of people are not explicitly addressed. As we saw, women in developing countries remain in the deepest part of the digital divide; however, only few studies have been conducted into women's uses of ICTs within particular communities.

The brief example provided here about women's village-phone use in Bangladesh highlights how the use of ICTs is embedded within women's social and cultural contexts. While Bangladeshi women's education levels are generally very low, mobile communication has shown to provide opportunities for illiterate people as well, and as the village phone is employed by other women in the community, the service has become rather accessible according to social norms. Even though the village phones are still used on a relatively small scale, the example of this program indicates that increased communication allows for more social and economic empowerment: Not only does the program allow for the improvement of women's economic status in terms of business practices (e.g., selling a product), but at the same time it also provides (some) women in the communities at large with more social inclusion because of the ability to reach family in neighboring villages, as well as to learn more about what is going on in their surroundings because of their enhanced mobility.

Even though this article only touches upon a few issues and is everything but exhaustive, it does point out areas where significantly more research is needed: namely, the social and cultural aspects of communities and their influence on ICT uptake. More research focusing specifically on women's communication needs as related to their cultural and social backgrounds is needed in order to develop and implement relevant communication technologies that may in the end allow for an incremental increase in women's social, political, and economic inclusion in society. This needs to not only happen for areas in Bangladesh, but for many locations across the globe. And, not only groups of women are in the digital divide; hence, empirical research on other disadvantaged groups of people and communities in particular locales will improve our understanding and may help us to better understand how culture relates to technology adoption and use. As the discussion has pointed out, social and cultural understanding is the number-one key to being able to implement appropriate systems that do just to people's current needs and at the same time do not interfere with current social and cultural practices.

KEY TERMS

Bangladesh: A developing Southern Asian country positioned as 138th out of 158 countries on the human-development index scale. It borders India and Myanmar, and has a population of 144 million people (in 2005), of which approximately two thirds work in the agricultural sector and 57% are illiterate.

Digital Divide: The (social) gap between (groups of) people who have and people who do not have access to information through the use of ICTs.

Information and Communication Technology (ICT): Includes both information technology for (computerized) information processing and communication technology such as (mobile) telephony communication.

Urban-Rural Digital Divide: The gap between rural and urban communities in their access to information through the use of ICTs.

ENDNOTES

1 Bangladesh is 138th out of 158 on the human-development index scale. See http://www.nationmaster.com/graph-T/eco_hum_dev_ind

Digital Divide, Gender, and the Indian Experience in IT

Rekha Pande
Maulana Azad National Urdu University (MANUU), India

INTRODUCTION

Information technology is being perceived as the magical wand and the harbinger of prosperity as it can guarantee access to global markets and enable direct foreign investment and e-commerce. Several projects aim at bringing information technologies to India with a belief in the transforming potential of IT. However, these technologies have created a digital and gender divide. In this article, attempts have been made to look into the digital divide and the constraints that women share by gender specifically in India.

India is a multilateral, multilingual, and multireligious society with many subdivides based on region, ethnic groups, class, and caste. The digital divide and gender has become yet another component of this diversity. In India, women comprise 14% of the IT industry and 26% of the business processing outsourcing (BPO) workforce. The total workforce of IT and BPO is made up of approximately 70 million people (http://www.ciol.com). At the lower experience level (about 3 years), about 19% of the workforce comprises women. At senior levels, women constitute less than 6% of the workforce (http://www.dqqindia.com). This indicates that few manage to reach the top level, and the majority of them remain at lower levels as computer or data-entry operators.

The gender gap in the digital divide is of great concern as it is directly linked to socioeconomic development. A major developmental issue of the coming decades will be the access and use of IT (Organization for Economic Cooperation and Development, 1989). Policy makers of both industrial and developing countries have agreed that IT is one of the fastest growing industries and is likely to be the largest by the turn of the century (Kraemer, 1994). Hence, if women are not actively present at all levels in this growing industry, then we would see marginalization that could undermine the advances made by women in other fields in the 20th century.

BACKGROUND

Colonial rule had deprived India of an industrial revolution. After gaining independence in 1947, India had adopted an economic policy that largely favored public-sector expansion. In this strategy, private and foreign capital were strictly controlled by the government. India's opting for a mixed economy also reflected the country's approach to high-technology industries (Harindranath, 1999). During this period, multinationals such as International Business Machine (IBM) and International Computer Limited (ICL) leased obsolete technology to India. Though the state-owned firm Electronics Corporation of India Ltd. (ECIL) entered into the indigenous manufacturing of computers in 1971, it could neither fully embrace the technology nor satisfy the growing demand of the country (Subramanian, 1992). In 1978, private-sector entrepreneurs entered the computer-manufacturing industry, which was supported by the national computer policy of 1984 (Government of India [GOI], 1984).

This above-mentioned policy was totally reversed in 1991 when the government of India adopted the New Economic Policy (NEP), which was further refined with stabilization and structural adjustment measures as advocated by the World Bank and International Monitory Fund (IMF). In 1998, GOI constituted a national task force on IT and software. The recommendations of this task force provided the directives, incentives, and concessions for the establishment and expansion of the IT industry in India. Accordingly, IT companies were exempted from income tax for 10 years. Further more, the govern-

Table 1. Knowledge professionals employed in Indian IT sector

Category	1990-1991	1996-1997	1999-2000	2000-2001	2001-2002
Software export sector			110,000	162,000	170,000
Software domestic sector			17,000	20,000	22,000
Software-captive in user organizations			115,000	178,114	224,250
IT-enabled services			42,000	70,000	106,000
Total	**156,000**	**160,000**	**284,000**	**430,114**	**522,250**

ment gave land for the building of IT companies. Concessions were also given on sales tax, electricity, and import duties (Chowdhry, 2002). As a result of all these efforts, India became an important player in the IT sector.

The software industry, which was started in the early 1970s, has grown at an exponential rate since the 1980s (Heeks, 1996). In the beginning, much of this work was carried out at the clients' facility located elsewhere rather than in India (Mitter, 2000). Recently, IT-enabled services such as call centres, customer interaction, back-office operations, insurance claims processing, medical transcriptions, and database management have further enhanced the scope of the IT industry in India. From a base of 6,800 knowledge workers in 1985 and 1986, the number increased to 522,000 software and services professionals by the end of 2002. It is estimated that out of these, almost 170,000 are working in the IT software and services export industry, nearly 106,000 are working in IT-enabled services, and 220,000 in user organizations (Table 1; http://www.nasscom.org.in). Hence, today IT is emerging as a major industry with increasing revenues (Figure 1).

WOMEN AND IT EDUCATION

Women's participation in the country's IT growth is determined by the low status ascribed to them in Indian society, extreme poverty, and poor IT infrastructure. Since most women lack literacy and basic education, specialized IT education is out of reach for many women. Like in many parts of the world, by and large girls take up courses in arts subjects only, and very few girls go for science subjects, especially engineering and IT. Female youth literacy is at 44%, and only 23% of India's Internet users are women (United Nations Education, Scientific and Cultural Organization, 1999)

Since very few women opt for engineering courses, an insignificant number of them pursue specialized training in IT. By and large, women face challenges in pursuing education at all ages because of the lack of time to attend school, familial and household duties, and sociocultural norms that give a low priority to education. In general, men are more aggressive than women, and this norm manifests itself in the interaction of boys and girls in the sharing and use of the computers. Recently, the National Institute of Information Technology (NIIT) conducted a project entitled Hole in the Wall in rural and urban areas. Their studies clearly indicated that computer use was evenly distributed between boys and girls in rural areas, but was higher among boys than girls in urban sites (Mitra, 2001).

It is common observation that women get less benefit from IT because of cultural restrictions imposed on their mobility. For example, it is often seen that fewer girls visit cybercafes than boys. Few IT-trained women would dare to move out of their hometowns and live alone in urban areas. Contrary to urban areas, the presence of IT in rural India is negligible. More than 60% of Indians live in villages, and women comprise at least 50% of them. There is an urgent need to introduce and expand IT in rural areas in order to create awareness among women. The digital divide in IT runs parallel to the rural-urban divide and the gender gap (International Telecommunication Union Task Force on Gender Issues, 2000).

INFRASTRUCTURE ISSUES

Despite its ambition to emerge as a global leader in the IT software sector, India lags behind in infrastructure. According to the Infrastructure Environment Index (IEI), it ranks 86th out of 104 countries. However, in the Environment Component Index (ECI), which measures the market, political, regulatory, and infrastructure environment, India ranks 38th (Financial Express, 2005). According to the GOI census of 2001, about 285 million Indians live in urban areas, a figure that approximates the population of USA. Out of 285 million, about 76 million Indians live below the poverty line in urban areas, which is equivalent to the population of Mexico. This still leaves 742 million Indians living in villages (http://infochangeindia.org/urban). Within the poorest households both in urban and rural India, women are poorest of the poor, which provides adequate evidence that IT access factors have a clear gender dimension. In general, in comparison to men, women suffer from an overload of demands on their time, leaving them with less opportunity to learn vocational skills in IT. The further lack of information and use of skills has a gender dimension as women's isolation gives them fewer opportunities to broaden their range of comprehension (Hafkin & Taggart, 2001). This suggests that there is a need and ample scope for the development of infrastructure in IT in both urban and rural areas, which may provide opportunities for more women to learn and join IT-related jobs.

GLOBALIZATION, INFORMATION TECHNOLOGY, AND WOMEN

Globalization involves the spatial and temporal reorganization of industries across borders and the spread of financial markets that resulted in integration and partnership building in flexible, commodity-based production systems. The field of operation is characterized by the redeploying and movement of capital across locations of their production at will.

The new vistas of business have now emerged as a global market. In many countries, women became the preferred candidates for certain jobs needed in a global economy. These ranged from manufacturing, where they were regarded as nimble, docile, and more able than men to perform repetitive tasks, to services (including everything from data entry to domestic and sexual services). A major motivation in shifting the geographical division of labor was the search for cheap labor, which was frequently associated with women workers (Hafkin & Taggart, 2001). Since the 1970s, an unprecedented number of women workers from developing countries entered both the formal and informal labor force to service the global economy, resulting in increasing marginalization and pauperization (Pande, 2000).

With the change in technology, women's work has considerably changed (Mitter, 1999) as follows.

- First, the work of women changed by the altering of the process of production in the manufacturing and service industries through automation, the de-skilling of workers, and the augmenting of the skill requirements of key jobs.
- Second, it changed through the introduction of new products or services in the market, such as electronics, computer peripherals, and information-processing work.

- Third, production that often uses old technologies shifted to locations that are distant from the main sites of commercial units or to home-based workers.

There has been a change even in the manufacturing sector. Employment in information technology in manufacturing has changed from making information technology in electronic assembly lines to using information technology in nearly every manufacturing industry. Globalized manufacturing still demands cheap labor, mostly located in the developing world, but with greater technical and cognitive skills. In the move to the knowledge economy, computer-literate, skilled technicians and engineers are needed, and nimble fingers have become largely redundant (Hafkin & Taggart, 2001). In spite of this change, women are conspicuously absent from decision making structure in developing countries. Decision making affects what the IT sector produces and how it organizes production and interacts with society. The existing systems of production and organization of the IT sector negatively affects women and continue traditional system of gender relations (Marcelle, 2000).

The emerging gender employment pattern in the IT sector is a cause for concern. Women are only employed in desktop publishing and software programming. A majority of them are employed in lower skilled IT jobs such as word processing and data entry. They are not employed in technical jobs such as designing, operating systems, and computer maintenance. Though globalization has opened vast opportunities in the IT sector, it has not improved the scope for women employment.

Overall in Asia, IT industry development followed two distinct phases. In the first phase, women were absorbed in the labor-intensive computer-assembly jobs (Castells, 1996). India also followed a similar route in the formative years of its IT industrialization, and women were absorbed in assembly-line jobs. In these jobs, women used to work for more than 10 hours a day; these were unusually long hours of work for miniscule wages according to any standard of measurement employed in judging the efficiency in developing countries. Furthermore, poor working conditions and exploitation by the employers added yet another dimension to women's employment in the potentially growing IT industry, particularly in India.

In the second phase that began in the 1980s, IT emerged as a service-provider industry. Accordingly, employment opportunities and employment patterns also changed. In this phase, manufacturing became more automated and required greater technical and cognitive skills than in the first phase. This resulted in a substantial drop in the number of women employees in the IT manufacturing industry.

Today, the world market for IT services is stated to be worth around $220 billion, and this is growing around 14% every year. India has several competitive advantages that enable it to tap into this huge market: the second largest pool of technical talent in the world after the USA, an attractive wage structure, and the possibility of providing clients a 24-hour workday by exploiting time-zone differences (Murthy, 2000). This new opportunity has once again opened a differential scope for women's employment in the IT industry. In the move to the knowledge economy, computer–literate, skilled technicians and engineers are needed. However, the jobs that are created in the new technology sectors are fewer than had been created in manufacturing. While globalization has brought new opportunities to young women with familiarity with English in new service-sector jobs, it has also made a vast number of women who are over 35 years old redundant (Pande, 2005).

India is emerging as the call-centre capital of the world, and many multinational companies and start-ups are setting up operations here. The worldwide demand for IT-enabled services is expected to grow at an exponential rate. As the sector with the most rapid momentum, it has been growing at a sustained pace of 50% per annum. According to an Industrial Design Centre (IDC) study, the Indian IT industry will grow to Rs. (Rupees) 247,000 crores ($53 billion) by the end of calendar year 2008 from Rs. 87,000 crores ($18.7 billion) in 2003 as per the India Brand Equity Foundation (http://www.ibef.org/industry/ITenabledservices.aspx). India hopes to capture a large share of this newly created market with revenues of $870 million from IT-enabled services in 2000 to 2001 with an annual growth rate of 66% (http://www.nasscom.org). This has been strongly supported by the data presented in Figure 1. Through these new technologies, a large amount of informa-

D

tion can be transported at very low cost from core office establishments to satellite or subcontracting units located around the globe. This possibility has led both private and public enterprises to externalize and decentralize noncore sections of their businesses to distant locations, often where trained human resource in IT is available at more economical and greater profitable rates than at the headquarters. Table 2 shows some of the latest available statistics with regard to outsourcing in India.

Outsourcing sites are often located in developing countries such as India, which have a comparative advantage in providing cheap workers who are skilled in computer use and have a good command of the English language. In this context, India has become an obvious and preferred choice of several multinational IT industries for establishing even full-fledged offices in cities such as Bangalore, Delhi, Hyderabad, and Chennai.

In some ways, the spread of IT-enabled services has been immensely beneficial to both women and men, especially those who have adequate skills but lack the resources to invest in higher education. The revenues in these services are increasing every year as shown in Figure 2. The employment of girls and women has grown enormously in these IT-enabled services such as the following:

- Call centres
- Back-office operations
- Medical transcriptions
- Online education
- GIS (geographical information system) services
- Computer-assisted animation

In these offices, job responsibilities have been restructured into two main components: administration support that deals with decision making, and technical support that is mainly responsible for the execution of tasks. The division of job responsibilities has infrastructural support by advanced tools in IT technology such as high-speed Internet, global connectivity to workstations, and high-volume communications networks. In general, it has become possible to spatially separate routine back-office tasks from nonroutine work (Greenbaum, 1995).

In general, minimum wages in India are just over Rs. 1,000 per month (about $20), but in the IT-enabled industry, wages can range from Rs. 5,000 to 15,000 ($102 to $306), which is 5 to 15 times more than normal minimum wages (Kelkar, Girija, & Veena, 2002). Therefore, employment for girls and women has become very attractive in some of these areas of outsourcing. Most of the women employed in call centres are between 20 and 25 years of age, and most of them work in back-office services; in most cases, this is their first job (Pande, 2005). As these services require rather routine, low-level, or limited technical training, women usually predomi-

Table 2. Recent figures related to IT growth

Figures	Estimates Related to India
$12.2 billion	Estimated worth of software exports by the end of 2005
21.7%	Expected annual growth in IT sector, which is the fastest in Asia Pacific
$4.9 billion	Estimated worth of India's information-technology market
$17.2 billion	Revenue from outsourcing in 2004 to 2005
$22.5 billion	Expected worth of back-office exports by the end of 2005
51%	Percentage of share in global outsourcing by 2008
$0.58	The cost saved on every dollar spent on offshoring by U.S. firms

nate here. Their jobs include activities such as taking customer calls, data entry, processing transcripts, service-claims processing, and remote sectary services. It is very difficult for these women to move into higher skilled, better paid jobs such as software development and programming or geographical information system analysis. There is no scope for the upgrading of skills, and women continue to work in the same kinds of jobs with only few degrees of variations.

One can observe a kind of hierarchy in the call-centre industry. Financial services such as those providing access to credit cards, insurance, stock markets, and bonds enjoy a higher status. Even sales and marketing enjoy a higher status than customer care. While the first is more output oriented, the latter is more quality oriented (Pande, 2005). Even if women are able to acquire better education and training and begin to enter IT fields in great numbers, women's leverage in the IT job market may be undercut by the feminization of labor. As computer-based skills become more commonplace and the need for more workers to use them in a greater variety of ways grows, more women will be again recruited but at lower wages. The recent law in America that stops government from outsourcing its work in developing countries will still hit at this sector.

Globalization has not changed the gender division of labor. The least skilled level of work with the lowest remuneration continues to be assigned to women following the nearly universal gender division of labor and patterns of work organization. For poor women, the existing inequalities and insecurities have intensified. Globalization has only widened gender disparities and increased the feminization of poverty (Pande, 2001). Some unskilled women have lost their livelihood as alternative sources produce goods cheaper and faster. For some women, it has meant a loss of rights, benefits, and job security. Globalization has also led to the migration of a large number of women from developing countries (Pande, 2000).

FUTURE TRENDS

Computer networks have altered the concepts of space and time. They allow multinational companies to provide real-time services all the time. Customer requests can be transferred across continents and time zones without the customer even knowing that work is being done on the other side of the world. For the first time, time and space independence is achievable for any business that operates in the global market. So, enabled by new technology, today's global businesses are not so much multinational as transnational (David, 1999). Hence, we will have more and more women entering IT.

In the future, all jobs related to information processing will be done entirely by women because of the association of women with typing and other kinds of secretarial work. Despite the assembly-line, "electronic-sweatshop" nature of the work, employers try to instill the idea of professional stature in the job by enforcing "pink-collar" dress codes of suit skirts and high heels, required by the job but not by the work (Freeman, 2000). Underlying the factory nature of the work, shift work is the norm with many companies operating around the clock. All this, however, will not ensure prosperity for women. Economic growth is not an end but a means to a better quality of life. One has to keep in mind the human face of economic growth.

The advent of globalization has brought changes even to the location of IT-enabled work. Women's work has been organized in two ways: home-based work and telework. In the first, using old technologies and facing increased international competition from automated manufacturers, companies shift production to the informal sector through subcontracting at reduced costs. Women who have lost formal-sector manufacturing jobs frequently turn to these less desirable jobs to remain in the labor force. The work here is done at home or in small units. Workers have none of the benefits of the formal sector, like fixed contracts, maternity leave, and unionizing. Like in other unorganized-sector work, they suffer from the lack of opportunities to work, low and discriminatory wages, and exploitative conditions resulting in casualization (Pande, 2002; http://twcu.ac.jp/). Teleworking is another kind of reorganization of women's work using new technology. Teleworking refers to distant working in which employers or freelance workers use telematics at a site that is geographically separated from the main site. As in IT-enabled services, this also involves a location set up, mostly in developing countries, that is different from the main office, which is often in developed countries. Many young girls join these and have to work throughout the night in order to keep up with Western time.

The rhetoric of globalization promises to remove backwardness through a worldwide exchange of information and skills in order to establish a truly cosmopolitan culture. There is an underlying belief that mutual cooperation and concern for social justice is automatically cared for under this system. In actual practice, since the global order is based on unequal power relations, these concerns are put on hold. Globalization creates the ghettoization of weaker nations and the weak among them. It seems to increase choices as trade does, but only for those with money and access to the market. Due to the existing differences between women's and men's access to knowledge, skills, responsibilities, concerns, and control over resources, they are affected widely by the global process.

It is a paradox of the information society that while on one hand the world is apparently shrinking all the time and distances never matter, where you are born and brought up has a lot of implication for your future. So, if you are an ambitious female computer-science graduate, you have a good prospect if you live in California or New York. But if you are born in India and live in Delhi or Hyderabad, you had better start practicing saying, "Hi, my name is Shirley. How can I help you?" and keep that smile forever in your voice while most of the others in your country are fast asleep, as the jobs that will be available will be only in IT-enabled services.

CONCLUSION

Therefore, to conclude, while information and communication technology has become a potent force for transforming social, economic, and political life in the globalized world, the gendered division of labor is already emerging. A large number of women tend to be concentrated in the end-user, lower skilled jobs and comprise a very small number among managerial, maintenance, and design personnel. In India, women's ability to participate in information technology is determined by the low status ascribed to women and girls in Indian society, and the extreme poverty and poor infrastructure that restrict women's access to education and information technology.

In the context of globalization and shifts in the structure of the international economy, technology-related changes in manufacturing processes have eliminated women's jobs or put them in new jobs with harsh conditions and low pay. IT-enabled services have recently expanded in India to build upon the traditional Indian values of quality, customer service, empathy, and courtesy. They have utilised the available human resources of a large pool of English-speaking youngsters and the globally competitive cost advantage. In some ways, the spread of IT-enabled services has been immensely beneficial to both women and men, especially those who have limited skills and lack the resources to invest in higher education. This has also brought some amount of mobility to single women, but by and large, it has not really changed gender relations at home.

Hence, while there are many subdivisions in India by region, class, race, caste, location, and ethnic origin, a major digital divide is by gender. Many of the constraints that women face are due to the poverty they share with men. The gender gap between men and women and how they benefit from information technology has widened because women receive less technical education when compared to men and are less employed in technology-intensive work. This is relatively true in rural areas among the poorer population, where women are already disadvantaged by their relative lack of education. Globalization has further complicated the issue. There has been an increasing feminization of lower level jobs. Technologies reveal the societies that invent them and use them, and their notion of social status and distributive justice. In opposition to global capitalism, there is a need for an alternative, community-based technology redefining knowledge in such a way that the local and diverse become legitimate, and women get equal representation. In India, the present technology and the way in which knowledge is constructed currently reflect men's world, and the struggle to transform it demands a transformation of gender relations.

KEY TERMS

Back Office: Operations defined as a wide range of noncore service functions of any organization that can be delivered off site.

Call Centres: Sometimes defined as telephone-based shared service centres used for a number of customer-related functions like marketing, selling, information dispensing, advising, giving technical support, and so forth.

Computer-Assisted Animation: Today, most production outfits use only computer-oriented technology for doing work. Graphics, animation, and special effects have become almost the sole preserve of computer systems.

Geographical Information System (GIS): Growth is driven by the rapidly spreading use of mapping and spatial-data technology in brand new disciplines by new customer-representing industries, markets, and applications.

Globalization: The process of businesses becoming international.

Information Technology: The use of technologies from computing, electronics, and telecommunications to process and distribute information in digital and other forms.

IT-Enabled Services: They typically include functions and services provided from a country different from the one where the end products are delivered. Services are either externally contracted (outsourced) or are provided by a remote subsidiary of the same company (out-located).

New Economic Policies: They consist of two measures—the stabilization and structural-adjustment measures—advocated by the World Bank and IMF. The former relates to the control of the fiscal balance and the balance of payments, and the latter aims at improving efficiency and productivity, and integrating the Indian economy with world trade and capitalist movements.

Online Education: Education occurring between two computers in the same town or between computers on the opposite sides of the earth.

Directing Equal Pay in the UK ICT Labour Market

Helen Richardson
University of Salford, UK

INTRODUCTION

The UK labour market is dramatically changing, with rapid technological innovations alongside globalisation where organisations are required to place a premium on human and intellectual capital. The demand for labour is outstripping supply, and businesses are increasingly dependent on their ability to attract, invest in and develop their workforce (Kingsmill, 2003). However, a recent comparative report of the information technology (IT) workforce in Holland, Germany and the UK indicates that women are haemorrhaging out of the IT sector (Platman & Taylor, 2004). Given that presently there is an IT specialist's skills shortage of 18.4% (IER/IFF, 2003), and female IT managers represent a mere 15% of ICT managers, 30% of IT operations technicians and 11% of IT strategy planning professionals (EOC, 2004a), this suggests that the ICT industry is not equipped for equality and diversity at work.

Despite many years of egalitarian rhetoric and 3 decades after the UK Equal Pay Act (1970) was introduced, women still receive on average 18% less than that of their male counterparts working full-time and 41% less than men when working part-time hours. The ESF-funded DEPICT project seeks to identify pay discrimination experienced by women in ICT at a national level throughout England. An important aim is to highlight the impact of pay and reward discrimination has on the underrepresentation of women in the ICT labour market. From this study, we hope to more clearly understand the reasons for the gender pay gap, particularly in the ICT sector; and the impact this has on women's entry and retention to occupations where they are already severely underrepresented. Equal pay is an issue for all; it's unjust, unlawful and impacts on social justice, equality and economic performance (EOC, 2001b). Pay is a major factor affecting relationships at work; distribution and levels of pay and benefits affect efficiency of organisations, workforce morale and productivity. It is vital for organisations to develop pay systems that reward workers fairly for the work they perform (ACAS, 2005).

WHAT IS THE GENDER PAY GAP?

The Equal Pay Act was enacted in 1970 and came into force in 1975 in the UK At that time, the gender pay gap stood at 36%—today, 35 years later, the pay gap remains obstinately at 18%. For women who work part-time, the pay gap is even larger, at 40%, similar to 30 years ago. The gender pay gap compares the earnings of female and male employees, while the gender income gap compares the individual incomes of all women and men. The gender gap between women and men's mean[1] individual incomes in 2002-2003 was 46%, and the gender gap between women and men's median income was 47%. (EOC, 2005c)

Thus, the gender pay gap is the difference in average earnings between men and women and is usually measured by hourly rate or weekly wage. Previous to the Equal Pay Act (1970), evidently the main cause of the gender pay gap was direct sex discrimination, and historically, women received up to half the pay of men even when performing the same job. After the introduction of the equal pay legislation, which prohibits employers from paying women less than men purely on the basis of their sex, the continuing gap was attributed to occupational segregation, indirect discrimination and human capital factors (for example, attainment of qualifications and experience).

ROOTS OF THE GENDER PAY GAP

The Equal Opportunities Commission (EOC) set up an Equal Pay Task Force in 1999 to explore the gender pay gap issue (EOC, 2001a). They reported three main contributors to the pay gap: occupational segregation, discrimination in pay systems and caring responsibilities.

- **Occupational Segregation:** The UK labour market is highly segregated, both horizontally and vertically. Horizontal segregation has led to 60% of the female workforce working in only 10 broad occupation types. Vertical segregation has evolved through a cluster of women working in lower-level jobs, often low skilled and low paid. Occupational segregation remains one of the strongest influences on young people's choice of career. Girls are still moving into industry sectors such as nursing, teaching and childcare. Boys continue to enter engineering, building services or ICT. Individuals' "life choices" are seriously compromised by occupational segregation; there has been no significant increase of women entering the construction, engineering, plumbing or ICT industries during the past 10 years (EOC, 2004a).
- **Caring Responsibilities:** In the UK women are still shouldering the main responsibility for childcare and increasingly taking the responsibility for the care of their elderly relatives. In these cases, women often have to work part-time, it is impossible for them to work long hours or they take time out of work. These factors contribute to the impact on women's earning power and promotion potential.
- **Discrimination in Pay Systems:** Organisations assume that because they have the same rate of pay for men and women then they have equal pay systems; however, pay systems are extremely complex (Neathey, Dench, & Thomson, 2003). Individualised pay is determined on value judgements and includes bonus schemes and performance-related pay. Women experience pay discrimination due to lower starting salaries, exclusion from bonus schemes, inability to qualify for long service awards and being awarded lower marks in performance assessments.

THE GENDER PAY GAP AND THE UK ICT LABOUR MARKET

On first inspection, ICT *gender pay gap* data gathered from the Office of National Statistics suggest a relatively small pay gap when comparing women's and men's hourly and weekly income (EOC, 2004a). For example, male ICT professionals earn on average £684.80 a week compared to the female ICT professional weekly wage of £619.80.

The figures shown in Table 1 portray the gender pay gap in the UK in a comparatively positive light. IT industry in a comparatively positive light; nevertheless, as most women are positioned at the lower end of the market, we assert that the *gender pay gap* is, in fact, greater than these statistics suggest and that *pay discrimination* is inherent in the ICT sector. There are limitations to statistical data on the "IT labour market"— research suggests that "working in IT" is an extremely difficult and complex sector to define (WINWIT, 2004). There are highly skilled women working in IT departments in many organisations and also in other industry sectors, such as the creative sector with design technologies and in new media industries. Taking this into consideration, we acknowledge that the IT sector is diverse and that much of women's engagement with IT may lay outside the traditional IT sector.

The ESF-funded DEPICT project seeks to investigate issues surrounding equal pay in the ICT sector as a result of the following factors:

- Individualised pay packages are common in the ICT industry, which involves requiring strong individual negotiation skills and a high level of confidence. Women have reported being uncomfortable with this method of pay-and-re-

Table 1. Gender pay gap data from the Office of National Statistics (2003)

	FEMALE		MALE		Gender Pay Gaps	
	Hourly	**Weekly**	**Hourly**	**Weekly**	**Hourly**	**Weekly**
ICT Managers	21.16	784.9	23.69	892.8	10.7	12.1
ICT Professionals	16.35	619.8	17.87	684.8	7.5	9.5

Source: Office of National Statistics (2003), New Earning Survey

ward negotiation, and find that masculine and aggressive organisational culture mitigates against success in such negotiation (WINWIT, 2004). Moreover, the ICT skills that women possess are often undervalued, marginalised or unrecognised regardless of achievement (WINWIT, 2004; Woodfield, 2000).

- There is a culture of "*salary secrets*" in the IT industry, and women have reported that they only find out about pay inequalities once they reach management level and have access to financial or personnel information. In research analysing gender equality in organisational pay structures and pay practices, including an initial evaluation of Equal Pay Reviews (Neathey et al., 2003), data revealed that more than 1 in 5 employers (22%) did not allow their employees to share information about pay with colleagues. Employers often expect confidentiality about pay and disclosing this information to colleagues can lead to disciplinary action.
- The Women in North West IT (WINWIT, 2004) reported gaps in annual salaries between male and female ICT professionals as much as £17,000. Women were also reported to have experienced discrimination in pay and promotion after returning from maternity leave and choosing to work family-friendly hours.
- Many women with caring responsibilities need to work part-time and this is often incompatible with working in the ICT industry, as part-time working is rarely an option.
- The current pension system operating in the UK is based on full-time, lifetime employment and is excluding workers who work part-time and people whose employment is disrupted by periods of unpaid domestic responsibility, which disproportionately impacts negatively on women (Prosser, 2005).

THEORETICAL FRAMEWORK FOR THE PROJECT

The economic, social and political root of women's inequality in the labour market is a contested theoretical area. This section discusses neo-classical, dual labour market theory and critical approaches to explaining women's inequality at work and the theoretical framework that is shaping this research.

Neo-classical economic theory explains women's pay discrimination in two main ways. First, there is an "individual" explanation suggesting that the wage paid to an individual relates to the value of the output that the individual produces. If women are paid less than men, this must be because the value of what they produce is less; that is, they are less productive (Richardson, 1984). *Human capital* theorists, on the other hand, try to link women's supposedly lower human capital to their role in the family. This view suggests that women have a "free choice" and indeed choose to obtain less education and training, choosing instead the role of child rearing. If women enter the labour market, this choice, therefore, has an impact on pay rewards.

Of course, these views can be criticised for suggesting an innate and rational economic view of the labour market and family relations divorced from actual experience. The state is involved in much of the organisation of the labour market and society through education and welfare policy, for example. Not all women share the same experience and choice of education and training, and such theories are attributing experiences to all women regardless of whether they work or have children.

Such approaches are now finding resonance in theories of the "information society" or "knowledge economy" (in particular, see Castells, 1996). Giddens (1984), concurring with Beck's individual and risk society thesis (Beck 1992), suggests that the changing situation of men and women in the family and at work must be seen in terms of individual choice: "We live in a world in which social order of the nation state, class, ethnicity and traditional family is in decline. The ethics of individual self-fulfilment and achievement is the most powerful in modern society" (Beck, 2002).

Taking a more practical view of the labour market, some theorists view a dual structure at work arising out of the need to cope with consumer and market fluctuations (see, e.g., Barron & Norris, 1976). In this approach, women dominate the secondary sector of employment, involving occupations with greater opportunities for dispensability and gender segregation, which more easily enables discrimination; a more acquiescent workforce because the wage is not always the sole income; and finally, a lack of solidarism because of the scattered nature of these secondary workplaces and preponderance of part-time work. This dual-market structure, therefore, affects women's overall position, and ideological factors both cause and effect women's inferior position within the labour market *and* the family.

Again, stereotypic assumptions form the basis of dual labour market theory (Beechey, 1980). It is implied that domestically women are reliant on men's wages and are only incidentally part of the workforce. This is not the reality for most women or the experience in most households (German, 2003).

Our research is shaped by critical and feminist approaches to understanding women's inequality in the labour market. Critical approaches to women's inequality largely are rooted in Marxist or Feminist theory. Feminist theories often locate women's inequality in patriarchal gender relations within capitalist relations. Women are thus divided along class lines but share the oppression of male domination. Capitalism and patriarchy in this way continually interacts, affecting women's position in the economy and family. This leads to the "economics of male advantage" (Cockburn, 1983, p. 8). In Marxist analysis, women's position in the labour market depends not on market principles, but arises from the organisation of production with roots in class exploitation. Inequality in the labour market is linked to women's oppression in the family. German (2003) explains that the family is both broken down by the effects of capitalism but also maintained and reinforced by capital as the cheapest, most convenient and most socially stable way of caring for the existing generation of workers and reproducing the next generation. The family fulfils too precious a role to be left to "free market" individualism. In reality, three-quarters of households are still headed by two-parent families, and men and women are moving closer together in terms of work and domestic life, but not in circumstances of their choosing. They do so "against a backdrop of continuing women's oppression and intensified exploitation for both men and women" (German, 2003, p. 31). Fitting into these roles is hard work—for women, it means working for less than equal wages and, for men, increased unpaid childcare in the home.

Yet the family is a gendered institution and is often taken for granted. Wharton (2005) describes how the family is viewed as "somehow functional for society rather than a social construction and changing in relation to history and culture" and she continues to observe that though family diversity is a social fact, this is "obscured by a set of taken-for-granted beliefs about the family as a social institution" (Wharton, 2005, p. 105). These include myths of the nuclear family, the heterosexual family, women as mothers and caretakers and men as fathers and breadwinners. However, it is these myths that inform the choices made, including government and employment policies. As Huws (2003) suggests:

... more than this, women's role in the domestic sphere is used to confirm and legitimate their marginal status in the labour market. The gendering of jobs cannot be reduced to a discussion of women in the domestic sphere, but must be seen as arising from the interplay between their socially ascribed, and therefore shifting, roles in both the public and private domains. (2003, p. 28)

RESEARCH METHODOLOGY

The ESF-funded research project DEPICT began in January 2005, with a detailed look at the causes of pay inequality between women and men. Researchers will draw upon expertise from steering committee members made up of representatives from the ICT industry, trade unions, academics, other agencies and upon background material by the *Equal Opportunities Commission* and other related literature.

The research will conduct qualitative research to gather primary data and will conduct in-depth semi-structured interviews with women entering, returning, working in or who have left the sector to ascertain their views and experiences on pay issues. Additionally, the study aims to produce supporting evidence via Web-based quantitative questionnaire that will be publicised on women's ICT forums, the aim of which is to gather data about pay from as many women working in the sector as possible to enhance the understanding of the complexities of the issue.

The project will end in December 2006, when a report will be prepared for the ESF and research results will be disseminated via workshops for organisations, women, local government representatives and other interested parties throughout England.

CONCLUSION

This article provides an overview of current research being undertaken by the ESF-funded DEPICT project at the University of Salford's Information Systems Institute that aims to investigate equal pay issues in the UK ICT sector. Despite 30 years of equal pay legislation in the UK, the gender pay gap still stands at 18%, the main contributing factors being occupational segregation, caring responsibilities and discrimination in pay systems The DEPICT project intends to highlight problems of overt and hidden pay discrimination and explore the implications these issues on have on women's progression and retention in the ICT industry, where women are already severely underrepresented. We present the argument that current data is limited, as the ICT sector is difficult and complex to define. We have presented a contextual theoretical framework for conducting the research by describing human capital theory and the dual labour market theory alongside critical approaches to explain women's inequality at work. The final section indicates a brief overview of the research methods that will be utilised during the research process.

KEY TERMS

Equal Opportunities Commission (EOC): The EOC is an independent, non-departmental public body, funded primarily by the government. Although independent from the government, they are responsible to the cabinet minister with responsibility for women and equality and to the deputy minister for women and equality in the Department for Trade and Industry.

Equal Pay Act: The Equal Pay Act covers discriminatory contractual terms related to pay and benefits (such as holidays, cars, etc.). The Act was amended by the Equal Pay (Amendment) Act 1983, which stated that men and women should be paid equally for work of equal value to their employers. This intended to tackle the fact that women tend to be occupationally segregated and so often cannot compare "like job with like." The Equal Pay Act only has jurisdiction for jobs done at an establishment within Britain. (The Sex Discrimination Act applies to any non- contractual payments of money or benefits; e.g., a one-off Christmas bonus payment.)

Gender Pay Gap: The gender pay gap is determined by calculating women's overall average pay as a percentage of men's. So, for example, the pay gap is said to be 18% where women's pay is 82% of men's. The gender pay gap is said to "narrow" as women's average pay moves closer to men's. To arrive at a figure for the gender pay gap, most official statistics compare the average hourly earnings of men and women working full-time as the best way to compare "like with like." This accounts for differences in hours worked.

Human Capital: Human capital theory suggests that women are rewarded for their previous investment in their own education and training; women do not receive the same rewards in terms of entry to employment, promotion and levels of pay received as men as a result of "choosing" to invest human capital in labour, such as childrearing.

Occupational Segregation: Occupational segregation is a major cause of the gender pay gap, which currently stands at 18% 30 years after the Equal Pay Act. In the UK, women are concentrated in a limited range of occupation types, predominantly in the lower-paid sectors of employment, such as catering, cleaning and caring.

Pay Discrimination: Since 1975, women and men have had the right to equal pay, but pay discrimination still takes place in many workplaces. Sometimes, women are paid less than men for doing the same job. In other cases, women are paid less than men for doing work of equivalent value for their employer. Both these forms of discrimination may be unlawful. Men paid less than their female colleagues also have a right to equal pay.

Salary Secrets: The "hidden truth" regarding pay inequality between men and women often go unnoticed until women reach senior management levels. Employers often require individual salary levels to be kept confidential.

ENDNOTE

[1] Mean individual income is the average, by calculating the sum of all earnings and dividing the total by the number of employees. However this total can be influenced by very high earnings of a few individuals and can present a distorted view of the "average."

Discrimination and Hostility Toward Women and Minorities in the IT Work Force

Peter Hoonakker
University of Wisconsin-Madison, USA

Pascale Carayon
University of Wisconsin-Madison, USA

Jen Schoepke
University of Wisconsin-Madison, USA

INTRODUCTION

There is substantial evidence for a critical shortage of skilled IT workers in the United States (Freeman & Aspray, 1999; ITAA, 2002). From 2000 to 2010, the occupation of computer specialists is projected to grow 69%, and the occupation of computer and information systems managers is projected to grow 48% (Hecker, 2001). Although demand for IT workers dropped in recent years (5% alone in 2001, ITAA, 2002), there is still a lack of *qualified* workers, referred to as the "gap" in IT workers. A large subset of this problem is the under representation of women and minorities in the IT workforce. It is possible that if women and minorities were represented in the IT workforce (ITWF) in proportion with their representation in the general population, the shortage of IT workers in the U.S. could be solved (CAWMSET, 2000; Freeman & Aspray, 1999). Some preliminary work has been done to identify barriers to the entrance and retention of women and underrepresented minorities in the ITWF (CAWMSET, 2000; ITAA, 2000), such as lack of role models and mentors, exclusion from informal networks, stereotyping and discrimination, an inhospitable atmosphere towards women, unequal pay scales and inadequate work/family balance (CAWMSET, 2000; ITAA, 2000; Panteli, Stack, Atkinson, & Ramsay, 1999).

BACKGROUND

Over the past few decades, there has been increasing recognition of the seriousness of different forms of misogyny and hostility toward women in the workplace (Miner-Rubino & Cortina, 2004). In particular, sexual harassment and its negative effects have received considerable attention (Fitzgerald, Drasgow, Hulin, Gelfland, & Magley, 1997). Until recently, most research on hostility has focused on the direct, active, physical types of hostile behavior that occur in work settings (Neuman & Baron, 1997). More recently, researchers have examined more subtle forms of hostility, such as rude, impolite behavior (Miner-Rubino & Cortina, 2004). Miner-Rubino and Cortina (2004) looked at how working in an organized context perceived as hostile toward women effects employee well-being, even in the absence of personal experience of hostility. Hostility toward women was found to be related to decreased well-being (work satisfaction and withdrawal behaviors) for both female and male employees. Gender discrimination and other forms of discrimination can be categorized into two practices: access and treatment (Levitin, Quinn, & Staines, 1971). Access discrimination emphasizes non-job-related qualifications on individuals, such as gender, race, age, and physical appearance, as limits for recruitment. Treatment discrimination is expressed in salary, job level, and status discrepancies. Treatment discrimination can affect not only tangible phenomena such as possible assignment, training opportunity, salary increase, promotion, termination, and layoff, but also subtle issues as acceptance in a work group or availability of career-enhancing and psychosocial support from supervisors and others (Ilgen & Youtz, 1986).

Based on data collected between 1988 and 1990, Truman and Baroudi (1994) found that access discrimination toward women does not take place in the ITWF, at least not for women at the highest educational levels (bachelor's and master's degrees). They suggested that access discrimination may be occurring at earlier stages (i.e., during the socialization process when women attitudes about appropriate job roles are formed), during the college admission process, or during the educational process. However, they found some evidence for treatment discrimination: women received lower salaries than men even when job level, age, education, and work experience were considered (Truman & Baroudi, 1994). There is relatively little information on access and treatment discrimination of minorities. Greenhaus, Parasuraman, and Wormley (1990) studied the effect of race on organizational experience, job performance evaluation, and career outcomes in a sample of 1628 black and white managers in three organizations. Race was found to have significant effects upon job performance evaluation, career plateauing and career satisfaction. Sanchez and Brock (1996) studied the effects of perceived treatment discrimination in a sample of 139 Hispanic employees. Results showed that a culturally relevant work stressor (i.e., perceived discrimination), contributed to employee outcomes above and beyond other work stressors.

In this article, we focus on unequal treatment, discrimination, and an inhospitable atmosphere towards women and minorities as possible reasons for high turnover of women and minorities in the ITWF. Turnover is highly related to quality of working life (QWL: job satisfaction, organizational commitment, and stress) in the ITWF (Baroudi, 1985; Hoonakker, Carayon, Schoepke, & Marian, 2004; Igbaria & Greenhaus, 1992). Therefore, we also examine the relation between unequal treatment, discrimination and a hostile environment, and QWL.

MAIN THRUST OF THE ARTICLE

Method

Two databases were used in the analyses. The *first database* has data of 624 male and female employees in five IT organizations in the U.S.: one large company (N>500), one medium sized company (N=200) and three small companies (N<100). The *second database* contains data of an international organization of female engineers and scientists employed in the IT field. In this second database, we only use data from 163 women employed in the U.S. Twenty-six cases had missing data on either gender and/or ethnicity1. See Table 1 for data on gender and ethnicity in the study sample.

We developed our own questionnaire based on existing scales; this questionnaire has been shown valid and reliable (Carayon, Schoepke, Hoonakker, Haims, & Brunette, 2006, in press). Two scales measured discrimination/unequal treatment. The first scale is adapted from Sanchez and Brock (1996) and contains two sets of questions. The first set of questions is aimed at personal experience of unequal treatment or discrimination, for example: "Have *YOU experienced* unequal treatment or discrimination at your current workplace on the basis of age, sex, having a family, being pregnant, etc. …" (see Table 2 for all sources of discrimination). The second set of questions asks about unequal treatment or discrimination at the workplace: "Do you believe

Table 1. Total sample by gender and ethnicity

	Men	Women	Total
Majority (White, not of Hispanic origin)	280 (85%)	361 (83%)	641 (84%)
Minority	48 (15%)	72 (17%)	120 (16%)
Total	328 (100%)	433 (100%)	761 (100%)

Table 2. Percentage of employees who have experienced unequal treatment of discrimination

Have *YOU experienced* unequal treatment or discrimination at your current workplace on the basis of:

	Majority		**Minority**		**All**	
	Men	Women	Men	Women	Men	Women
Age (against the young)	4%	6%	6%	10%	4%	7%
Age (against the old)	3%	8%	11%	7%	4%	8%
Sex (against women)	1%	25%	4%	26%	2%	25%
Sex (against men)	3%	0.6%	6%	4%	4%	1.2%
Having a family	4%	13%	2%	11%	4%	13%
Being pregnant	0.4%	5%	2%	4%	0.6%	5%
Favoritism	20%	38%	22%	48%	20%	40%
Race	0.4%	1.4%	9%	24%	2%	5%
Nationality	0%	4%	9%	14%	1%	5%
Color	0.4%	1.4%	2%	20%	1%	4%
English language capability	0.7%	3%	7%	13%	2%	5%
Disability	0.7%	2%	2%	3%	0.9%	2%
Religious orientation	0%	2%	4%	4%	0.6%	2%
Sexual orientation	1.5%	2%	4%	3%	2%	2%
Education level	4%	10%	11%	24%	5%	12%
Temporary employment relationship	3%	6%	4%	14%	3%	5%
Part-time employment relationship	4%	9%	2%	13%	2%	7%

that unequal treatment or discrimination occurs at your current workplace on the basis of: age, sex, having a family, being pregnant, etc. …" (see Table 3). Response categories for both sets of questions are yes/no/not applicable.

The second scale is adapted from Lehto and Sutela (1999) and targets discrimination on the basis of ethnicity and cultural background. Examples of items include: "At work, I feel uncomfortable when others make jokes or negative commentaries about people of my ethnic or cultural background" and "At work, I do not get enough recognition because I am different." Response categories for this scale are: strongly disagree—disagree—neither agree nor disagree—agree—strongly agree—not applicable. Cronbach's α for this scale is 0.95.

To measure the general atmosphere towards men, women and minorities in the work environment, we used six dimensions adapted from Fiedler (1967), such as unfriendly/friendly and hostile/supportive (see Figure 1). Respondents were asked to rate the general atmosphere at the workplace towards men, women, and minorities. Three sets of questions were asked, such as: "Describe the general atmosphere in your company for female IT workers (male IT workers and minority IT workers): 1 unfriendly—8 friendly; 1 hostile—8 supportive etc. …". *The general atmosphere scale was only used in the second sample of female scientists and engineers*. Reliability Cronbach α scores are 0.97 for the scale for atmosphere towards women, 0.95 for the scale atmosphere towards men, and for 0.98 for the scale of atmosphere towards minorities.

For a description of the measures of Quality of Working Life (QWL), see Carayon et al. (2006). Turnover intention was measured with a single item: "How likely is it that you will actively look for a new job next year" on a 7-point scale ranging from 1: not at all likely – 2-3: somewhat likely – 4-5: quite likely – 6-7:extremely likely (mean = 2.87, sd = 1.83). The QWL scales and the item on turnover intention were used in both databases. *All scale scores and the item on turnover intention have been recoded to scores between 0 (lowest) and 100 (highest).*

Results

Unequal Treatment or Discrimination

Table 2 shows the percentage of employees who have *personally* experienced unequal treatment or discrimination on the basis of several factors.

Results show that the form of unequal treatment or discrimination most often experienced personally by all respondents is favoritism. Both white women and women belonging to minority groups have more often personally experienced favoritism than men.

Unequal treatment on the basis of gender is the second most often experienced form of unequal treatment: about 25% of women have experienced unequal treatment on the basis of gender. Unequal treatment on the basis of having a family and educational level are other forms of unequal treatment that respondents report having experienced. Unequal treatment on the basis of race, nationality, color, disability, religious orientation, and sexual orientation has been less often experienced by the respondents.

Table 3 shows the percentage of respondents who report that unequal treatment or discrimination occurs *at their workplace*.

Results show again that the most frequent form of unequal treatment at the workplace is favoritism. Interestingly, both minority and majority men think that it occurs less often than women. About 1/3 of the women believe that unequal treatment or discrimination occurs at the workplace on basis of gender, as compared to 8% of the men. Minorities believe that unequal treatment or discrimination on the basis of race takes place at the work place. Both men and women, and minorities and majorities believe that unequal treatment or discrimination on basis of educational level takes place at the workplace. Women (26%) report this type of discrimination significantly more than men (13%).

Discrimination Based on Ethnicity/Cultural Background

Respondents were asked questions about discrimination based on ethnicity and cultural background. Table 4 shows the results of the scale scores by gender and minority status.

A univariate analysis of variance shows a significant gender effect ($F=37.3$, $p<0.001$), a significant minority/majority effect ($F=11.7$, $p<0.001$) and a nearly significant interaction effect ($F=3.5$, $p=0.06$). Women feel significantly more discriminated against than men; minorities feel more discriminated against

Table 3. Percentage of respondents who report unequal treatment or discrimination at their workplace

Do you believe that unequal treatment or discrimination occurs *at your current workplace* on the basis of:

	Majority		**Minority**		**All**	
	Men	Women	Men	Women	Men	Women
Age (against the young)	7%	9%	4%	17%	7%	10%
Age (against the old)	10%	21%	9%	27%	10%	22%
Sex (against women)	7%	32%	13%	41%	8%	33%
Sex (against men)	5%	2%	6%	6%	5%	2%
Having a family	7%	23%	4%	10%	7%	21%
Being pregnant	4%	17%	2%	14%	4%	16%
Favoritism	32%	51%	25%	56%	31%	51%
Race	5%	14%	22%	31%	7%	17%
Nationality	5%	12%	16%	23%	7%	13%
Color	4%	11%	19%	28%	6%	14%
English language capability	14%	19%	15%	29%	14%	21%
Disability	4%	8%	2%	17%	4%	10%
Religious orientation	1%	4%	6%	7%	2%	4%
Sexual orientation	3%	7%	11%	11%	4%	8%
Education level	13%	24%	15%	33%	13%	26%
Temporary employment relationship	8%	14%	2%	17%	7%	15%
Part-time employment relationship	6%	15%	2%	17%	5%	15%

Table 4. Discrimination based on ethnicity/cultural background by gender and ethnicity

	Majority		Minority		All	
	Men	Women	Men	Women	Men	Women
Discrimination	19.2	29.8	22.8	39.9	20	32
All	24.7		33.4		26	

Figure 1. The general atmosphere towards men, women, and minorities

	1 unfriendly - 8 friendly	1 rejecting - 8 accepting	1 frustrating - 8 satisfying	1 cold - 8 warm	1 hostile - 8 supportive	1 unfair - 8 fair
Men	7.3	7.3	6.9	6.9	7.0	7.0
Women	5.8	5.7	5.0	5.3	5.4	5.3
Minorities	5.9	5.8	5.5	5.5	5.7	5.6

than the majority (Whites); and female minorities feel more discriminated against than male minorities.

General Atmosphere in the Company Towards Men, Women, and Minorities

Respondents in the second sample were asked to describe their work environment on six dimensions, such as unfriendliness-friendliness and accepting-rejecting, using a 1-8 scale (1 = negative, 8 = positive) (see Figure 1).

The general atmosphere towards women is perceived as significantly more unfriendly, rejecting, frustrating, cold, hostile, and unfair than the general atmosphere towards men, and also significantly more frustrating, cold and unfair than the general atmosphere towards minorities.

Effects of Discrimination Based on Ethnicity and/or Cultural Background and the General Atmosphere Towards Gender and Ethnicity on QWL and Turnover

In order to study the effects of discrimination on QWL and turnover intention, we divided the sample in two groups using the median score: the first group experiences (relatively) little discrimination, and the second group experiences (relatively) more discrimination. Then, we compared the mean scores of the groups on QWL and turnover intention, using an independent sample T-test. See Figure 2 for the results of this analysis.

Discrimination based on ethnicity and/or cultural background significantly affects job satisfaction, organizational commitment, and stress. Respondents who perceive lower discrimination are significantly more satisfied with their jobs, are more committed to the organization, and suffer less from stress. However, the difference between the groups on turnover intention is not statistically significant.

Table 5 shows the effect of the general atmosphere towards men, women, and minorities on QWL and turnover intention. Using the median score, we created two groups (negative and positive atmosphere). Twenty-one percent of the respondents in the second database belong to a minority group.

Results show that the perception of the female scientists and engineers regarding the general atmosphere towards their male colleagues does not affect QWL and turnover intention. As shown in Figure 1, they perceive the general atmosphere towards men as much friendlier than the atmosphere towards minorities and female employees. It does matter significantly how they perceive the general atmosphere towards women in their organization. If

Figure 2. Effects of discrimination on QWL and turnover intention

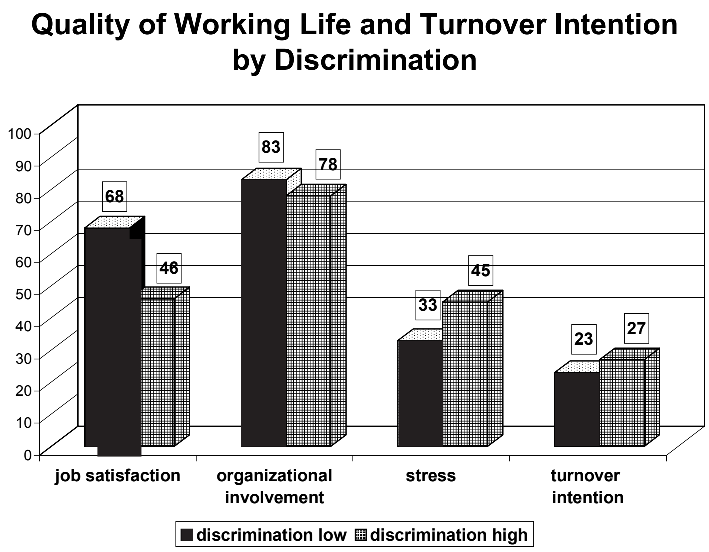

Table 5. Effects of perceived atmosphere towards men, women, and minorities on QWL and turnover intention

	Atmosphere towards male employees		Atmosphere towards female employees		Atmosphere towards minorities	
	Negative (N=74)	Positive (N=84)	Negative (N=83)	Positive (N=80)	Negative (N=76)	Positive (N=56)
Job satisfaction	64	65	53	77***	56	74***
Organizational involvement	86	88	85	88	86	89
Stress	48	48	56	39***	54	40***
Turnover intention	46	46	60	33	57	32

*Note: *** Differences between positive and negative atmosphere are statistically significant at p<0.001*

they perceive the atmosphere as being negative, they report significantly less job satisfaction, more stress, and greater turnover intention. The same holds true for the atmosphere towards minorities. If respondents perceive the atmosphere towards minorities as negative, they report significantly less job satisfaction, more stress, and higher turnover intention.

FUTURE TRENDS

According to statistics from the U.S. Department of Commerce and the Census Bureau, women represent 46% of the total workforce, but only 30% of the IT workforce. Blacks hold only 5% of IT workforce jobs, yet make up more than 12% of the country's population. Hispanics hold less than 5% of IT workforce jobs and make up nearly 12% of the U.S. population. More research and interventions are needed to identify and solve possible causes of the low entrance and retention of women and underrepresented minorities in the IT work force. Especially because the number of women in the IT workforce is dropping and the number of Hispanics in American society is growing rapidly.

CONCLUSION

In this article, we focused on unequal treatment, discrimination, and the general atmosphere towards men, women, and minorities in IT organizations as possible sources of job dissatisfaction and turnover among women and minorities. Results show that unequal treatment and discrimination occurs very often as reported by the study participants. Especially favoritism seems to occur quite often, but also unequal treatment of women and minorities for various reasons. Second, results show large differences in how men, women, and minorities perceive unequal treatment and discrimination in the work place. Women and minorities report that this takes place more often than men. Third, significant differences in the perceived atmosphere towards male and female employees and minorities in IT organizations were found: general atmosphere towards women is perceived as significantly more unfriendly, rejecting, frustrating, cold, hostile, and unfair than the general atmosphere towards men, and also significantly more frustrating, cold, and unfair than the general atmosphere towards minorities.

In addition, discrimination based on ethnicity/cultural background is significantly related to low job satisfaction, low commitment, and high stress, but not related to turnover intention. There may be several explanations for this. First, the impact of discrimination on turnover intention may be moderated by job satisfaction and organizational commitment. Job satisfaction (and to a lesser extent organizational commitment) predict turnover in the ITWF (Hoonakker et al., 2004; Igbaria & Greenhaus, 1992). Another possible explanation is that employees do not expect the situation to be different in other (IT) organizations. A perceived hostile atmosphere towards women and minorities in an organization is significantly related to turnover intention, low job satisfaction, and high job stress, but not related to organizational commitment.

A limitation of this study is that all minorities were grouped into a single category. Obviously, there are many differences between African-Americans, Asians/Pacific Islanders, Hispanics, Native Americans, and other minorities. The minorities are under represented in our sample as they are in the ITWF. Breaking up the group in smaller groups would make our statistical analyses unreliable. However, there is one exception to the under representation of minorities in the ITWF: Asians/Pacific Islanders. Therefore, we looked at possible differences between Asians/Pacific Islanders and other minorities. Results show that Asians/Pacific Islanders report to be as much discriminated against as other minorities. This does not explain the higher entrance rates and retention of Asians/Pacific Islanders in the ITWF. However, additional analyses show that Asians/Pacific Islanders are significantly higher educated than other minorities and whites. For example, in our sample 48% of the Asians/Pacific Islanders hold a graduate or professional degree vs. 31% of the whites and 23% of the other minorities. Apparently, education plays an important role in entrance and retention in the ITWF.

NOTE

Funding for this research is provided by the NSF Information Technology Workforce Program (project #EIA-0120092, PI: P. Carayon).

KEY TERMS

Access Discrimination: Places non-job-related qualifications on individuals, such as gender, race, age, and physical appearance among others, that limit or bar their recruitment.

Discrimination: Involves formally or informally classifying people into different groups and according the members of each group distinct, and typically unequal, treatments, rights and obligations.

Gender Discrimination: Can be classified into two practices: access and treatment (Levitin et al., 1971).

IT Organization: Basically, an organization is a group of people intentionally organized to accomplish an overall, common goal or set of goals. An IT organization is an organization where information technology is used to accomplish the common goal or set of goals. This definition is much larger than the definition for IT company: a company that *produces* Information Technology (hardware and/or software). Estimates show that 90% of IT employees are employed in non-IT companies, such as hospitals, banks, insurance companies.

Minority: A group within a country that differs in race, religion, or national origin from the larger part of the population. The following groups are considered minorities in the USA: Afro-Americans; Asians/Pacific Islanders; Hispanics and Native Americans. The majority is White (not of Hispanic origin). Note however, that in the ITWF, Asians/Pacific Islanders are not considered an underrepresented minority. In the ITWF, Asians/Pacific Islanders are relatively overrepresented.

Quality of Working Life (QWL): Represents the quality of the relationship between employees and their total working environment, with human dimensions added to the usual technical and economic considerations.

Treatment Discrimination: Is manifested in salary, job level, and status-symbol discrepancies. Treatment discrimination can affect not only such tangible phenomena as possible assignments, training opportunities, salary increases, promotions, terminations, and layoffs, but also subtle issues as acceptance into a work group or the availability of career-enhancing and psychosocial support from supervisors and others (Ilgen & Youtz, 1986).

Turnover or Labor Turnover: The movement of workers in and out of employment with a particular firm. Labor turnover is typically measured in terms of the separation rate (quits, layoffs, and discharges per 100 employees on the payroll).

Withdrawal Behaviors: Constitutes a cluster of behaviors that reflect attempts to avoid one's work task (e.g., absenteeism; tardiness; missing meetings).

ENDNOTE

1 Note that Asians and Pacific Islanders are not considered an underrepresented minority in the ITWF. However, we have no reason to assume that discrimination based on race, ethnicity, cultural, background and language capabilities does not affect Asians and Pacific Islanders. Therefore, Asians and Pacific Islanders are included in the minority group along with Hispanics and African-Americans.

Diversity in Studying Gender and IT

Michael J. Gallivan
Georgia State University, USA

INTRODUCTION

Over the past decade, the IS literature has been transformed from one that has virtually ignored gender issues to one in which gender frequently appears center stage. Just 8 years ago, Gefen and Straub (1997, p. 390) noted that "gender has been generally missing from IT behavioral research." Other scholars have also drawn attention to the paucity of gender research in the IS literature even into the 21st century. For instance, Adam, Howcroft, and Richardson (2004, p. 223) noted that "whilst interest in gender has begun to permeate and influence other disciplines, the domain of IS has remained fairly watertight against incursions from gender analysis." In the past few years, however, the IS field has made considerable headway in terms of the number of studies that address gender analyses of IT use and women's experiences in the IT profession. Some advances include special journal issues (Adam, Howcroft, & Richardson, 2002; Gurak & Ebeltoft-Kraske, 1999), an edited book (Green & Adam 2001), and even a focused IS conference track on gender and diversity issues.[1]

This growing interest in the subject of gender and IT has been accompanied by recent claims by scholars regarding appropriate ways to define, conceptualize, and study gender. For instance, the first papers in leading North American journals that prominently featured gender during the 1990s were all quantitative, survey-based studies—either of gender differences in IT use (Gefen & Straub, 1997; Venkatesh & Morris, 2000) or comparative studies of men and women IT employees (Igbaria & Baroudi, 1995; Truman & Baroudi, 1994). Adam et al. (2004) criticized such quantitative approaches to gender in their conceptual review of gender in IS research, noting three shortcomings: Such studies (a) overlook the literature on gender from the social studies of technology field, (b) dichotomize gender into a nominal category, and (c) fail to provide a rationale for why the experiences of men and women differ with regard to IT. They conclude that:

> *... it is the style of explanation that is problematic in these papers. In a nutshell, this research has difficulty explaining the phenomena it apparently uncovers as it does not adequately theorise the construct of gender, nor indeed the construct of technology.* (p. 227)

Their critique of many studies is on target, especially quantitative studies in which the authors neglect to provide insights into factors that shape the different experiences of men and women regarding IT usage or IT-related career experiences. A variety of labels have been employed to describe the underlying logic for why men's and women's experiences and behavior may differ: *social constructivism* (Wilson, 2002), *social shaping* (McKenzie & Wajcman, 1985), *essentialism* (Wajcman, 1991), *feminist standpoint theory* (Harding, 1991), *radical feminism* (Daly, 1992), the *individual-differences perspective* (Trauth, 2002), *gender as performance*, and others. Some of these traditions of scholarship related to gender are more popular in different parts of the world, in different academic disciplines, and at different times in the evolution of various disciplines.

The key message that readers should draw from this critique by Adam et al. (2004) is that all researchers should clearly articulate their conceptualization of gender, including fundamental beliefs the authors hold for what gender means and for why the attitudes, behaviors, and experiences of men and women may be similar to or different from each other. Such articulation of authors' beliefs about gender is highly advantageous—whether their studies compare the beliefs or experiences of men and women, or whether they examine just women (or men) in isolation. Second, I support the advice by Adam et al. that researchers should be cautious about citing certain theories as explanations for differences between men and women whose premises were grounded in an earlier era given that we live "in a world where women make up a much larger proportion of the workforce than when many of the original reference studies were conducted" (p. 228).

On the other hand, it is important that researchers not conclude from their critique of the gender and IS literature that all quantitative, positivist studies of gender and IT are necessarily suspect. I fear, however, that many readers will draw exactly this conclusion. If one were to dismiss all quantitative, positivist studies on IT and gender, this would eliminate nearly 75% of the studies of gender and IT that have been published to date. To reject these studies would, in effect, return us to an era that Adam et al. (2004, p. 223) criticize as being characterized by "difficulties of finding published research on the topic of gender and IS, whether that be interpretivist or positivist in emphasis."

MAIN THRUST OF THE ARTICLE

One common assumption appears to be that quantitative studies that statistically analyze data to identify differences between men and women are misguided because they necessarily assume an essentialist view that that men and women are innately different from each other. While some quantitative scholars certainly subscribe to essentialist beliefs, citing prior literature on innate biological or psychological differences between men and women (as Venkatesh & Morris, 2000, do in citing early research from cognitive psychology), not all quantitative scholars who study gender and IT share such essentialist beliefs. Indeed, researchers who conduct comparative studies need not accept essentialist or deterministic explanations as the underlying reason for the differing experiences of men and women with regard to IT or IT careers. Treating gender as a nominal variable (one that facilitates comparative analysis, whether qualitative or quantitative in nature) is also consistent with a view that gender is socially constructed. For instance, in her qualitative comparative studies of IT use and resistance, Wilson (2004, p. 84) argued that differences between the experiences of men and women are "based on the role of socialization in creating gender difference—rather than ... [different] innate abilities and characteristics." Similarly, Woodfield (2002) also conducted comparative studies of men's and women's experiences in IT careers, offering a social-constructivist explanation for the specific skills and attributes that have been ascribed to women vs. men:

> *My own position on the question of whether women are indeed more socially skilled than men is that women as a group, by dint of their socialisation, are typically more relational in focus, more people-oriented, and often have a more co-operative style of interaction.* (p. 121)

Thus, scholars who conduct comparative studies of the beliefs, actions, and experiences of men and women need not subscribe to essentialist or determinist tenets that men and women are innately different from each other. Of course, researchers who write about gender should clearly explicate their beliefs regarding the meaning of gender and the underlying factors that shape men's and women's experiences regarding IT and IT careers, whether their work is comparative or not. Such scholars may subscribe to essentialist, social constructivist, radical feminist, feminist standpoint, or any of a host of explanations and philosophical traditions regarding the meaning of gender and the reasons for similarities and differences between men and women.

We should be skeptical of all studies that neglect to offer any definition of gender or conceptual basis for the differences they posit between men and women; yet, we must also let the authors speak for themselves rather than draw the unwarranted conclusion that all scholars who analyze comparative, quantitative data on men and women believe in essential, inborn differences between the sexes. Nor should we assume that all qualitative researchers who study gender necessarily assume a social-constructivist perspective on gender. Such views, however, are implied in the statements quoted from Adam et al. (2004), above. As further validation of my argument that quantitative researchers do not all subscribe to essential differences between the sexes, nor do all qualitative researchers hold social-constructivist beliefs, I conducted a literature search of all studies on IT and gender published in the decade from 1994 to 2004. I searched for articles in six online databases that index scholarly IS journals, searching for specific keywords[2] in their titles or abstracts. I found 112 papers published in this interval, with just over half from peer-reviewed journals and the rest from scholarly conferences.

Of this body of work, I classified the papers into five subject areas: 53% of the studies focused on gender issues related to the experiences of IT professionals or students, 31% of the studies examined IT usage and associated user attitudes, 8.5% analyzed gender issues related to computer ethics, 3% analyzed issues related to IT faculty (e.g., hiring practices and publication patterns), and 4.5% considered respondents' attitudes to IT-enabled changes, such as telecommuting, distance learning, and virtual teams. There were also two broad review papers on gender and IS spanning several subjects, which could not be classified into any of the four topics (Adam, 2002; Adam et al., 2004). A total of 110 papers were classified by subject area.

There were a total of 13 conceptual papers, all but two of which articulated the authors' views regarding the underlying reasons for any observed differences between men and women. After removing the two papers spanning multiple subject areas, this left 11 conceptual papers on topics ranging from IT careers (Ahuja, 2002; Kase & Trauth, 2003; Tapia & Kvasny, 2004; von Hellens & Nielsen, 2001) to IT education (Cukier, Shortt, & Devine, 2002), computer ethics (Adam, 2001; Adam & Ofori-Amanfo, 2000), gender issues in designing software (Powell & Johnson, 1995), gender in cyberspace (Westfall, 2000), and the gendered nature of IT in the workplace (Wilson, 2004).

There were 57 studies concerning gender issues related to IT careers or education. Another 33 studies examined IT usage: 27 quantitative studies plus 3 qualitative studies (Kvasny, 2003; McDonough, 1999; Wilson, 2002) and three conceptual studies (Powell & Johnson, 1995; Westfall, 2000; Wilson, 2004). Nine studies examined computer ethics, including seven quantitative studies, two conceptual papers (Alison, 2001; Alison & Ofori-Amanfo, 2000), and no qualitative studies. Finally, there were four additional studies dealing with attitudes toward IT-enabled changes in organizational practices, all quantitative. These studies examined employees' or students' attitudes to telecommuting (Belanger, 1999; Mokhtarian & Bagley, 1998) or virtual teams (Lam & Ching, 2001; Lind & White, 2000).

I classified all empirical studies, first by the five subject areas; second, as qualitative or quantitative; and third, based on the authors' stated rationale for any hypothesized or observed gender differences (essentialism, social constructivism, critical feminism, feminist standpoint theory, etc.). In doing so, I found the seven studies of computer ethics especially interesting. All seven of these quantitative studies (Kreie & Cronin, 1998; Loch & Conger, 1996) stated *a priori* hypotheses regarding gender (e.g., that women would exhibit more ethical behavior regarding software piracy), but none of the authors specifically explained what they meant by gender. They neither explicitly claimed that men and women are innately different due to biological factors, nor did they argue that gender represents a social construction. Due to such ambiguity about the authors' beliefs, I labeled all of these computer-ethics studies as "unclassified".

Of 20 qualitative studies, 8 defined gender and explained the authors' beliefs about the reasons for the observed differences between men and women, yet 12 other qualitative studies neglected to do so. Of 75 quantitative studies, only 4 offered an underlying logic for the different behaviors exhibited by men and women: either essentialism (Venkatesh & Morris, 2000), socially constructed gender schemas (Roldan, Soe, & Yakura 2004), or socialization based on Hofstede's notion of masculine and feminine cultures (Gefen & Straub, 1997; Simon, 2001). All other quantitative studies neglected to define gender or the authors' beliefs about the forces that shape the actions and experiences of men and women.

In terms of lessons that can be drawn from this classification, we see that conceptual studies were much more likely to provide a definition of gender, thus articulating the authors' beliefs regarding the forces that shape the experiences of men and women: 77% of conceptual papers did so, compared to 42% of qualitative, empirical studies and less than 6% of quantitative studies. Thus, the critique offered by Adam et al. (2004) is, in part, supported: Qualitative researchers who study gender and IT are more likely than their quantitative peers to articulate their beliefs about gender, including possible reasons for the different behaviors and experiences of men and women. On the other hand, the implication that quantitative researchers all subscribe to essentialist beliefs appears unfounded: Just one set of authors articulated a definition of gender that could be construed as essentialist, while other authors specified a social-constructivist view (Roldan et al., 2004) or concepts derived from Hosftede's views about socialization into masculine and feminine cultures. Most researchers who published quantitative studies simply compared results for men and women without mentioning their beliefs about gender (whether essentialist or otherwise).

CONCLUSION

Most qualitative and quantitative studies in the IS literature can be criticized on the grounds that their authors neglect to offer any explanation for the hypothesized or observed differences between the men and women they study. It is important for all researchers who study gender and IT to make their beliefs about the reasons for similarities and differences among men and women explicit. This review of 112 published studies reveals that there is insufficient evidence to conclude that most quantitative researchers who conduct comparative studies on gender (i.e., treating gender as a nominal variable by comparing the beliefs and experiences of men and women) subscribe to essentialist notions. This is because 95% of quantitative researchers neglected to specify any grounds for the differences they analyzed. Likewise, most qualitative researchers (60%) also neglected to offer any conceptual basis to explain what they meant by gender or any differences they found between men and women. There is no reason to believe that all or most scholars who conduct quantitative research on gender and IT subscribe to essentialist beliefs. Many of these researchers may strongly believe, like their qualitative peers, that gender is a social construction.

In fact, comparative, quantitative research may support social-constructivist beliefs, as noted by philosopher Janet Wesselius (1998), who argues that treating sex as a nominal category for comparison purposes need not assume underlying essential differences. Rather, Wesselius claims that it is appropriate to consider men and women as distinct categories for purposes of comparison due to what Fuss (1989) labels a *nominal essence*, as opposed to a *real essence*:

> *Real essences refer to the fixed properties of things; nominal essences refer to the way we categorize and label things ... [W]e can recognise that some humans have been assigned a nominal or socially constructed essence as women; that is, women are the same to the extent that they are treated as the same. Women share a common categorization whether or not this is the result of a real essence. By seeing the commonality that women share as a socially constructed essence, we can account for women as a category without suppressing difference [among them].*

There will always be some scholars who believe that men and women are innately different due to inborn factors, and quantitative studies that treat gender as a nominal category are consistent with such views. Yet, such essentialist notions cannot be assumed to characterize all or even most quantitative researchers. Quantitative studies of IT and gender should thus be evaluated on their own merits based on the authors' explicitly stated rationales for their gender beliefs rather than rejected as a whole.

KEY TERMS

Essentialism: The belief that men and women are innately different due to inborn biological factors.

Feminist Standpoint Theory: The belief that socially oppressed groups (e.g., women and ethnic minorities) can access knowledge that is unavailable to members of socially privileged groups.

Gender as Performance (Performative Theories of Gender): The view that gender is a verb (i.e., gendering or doing gender) and should be analyzed as a process rather than a fixed state.

Individual-Differences Approach: The view that gender is socially shaped, but in distinct ways for each individual, due to the individual's unique history, culture, and personal experiences.

Social Constructivism: The belief that gender is a social convention whereby social norms dictate acceptable attributes and behaviors for men and women, including their choice of careers.

D

ENDNOTES

1. In 2003, the Americas Conference on IS (AMCIS) initiated a track titled *Diversity in the IT Workforce* that has featured over 15 papers to date on topics such as gender and ethnic diversity in IT careers and in IT usage.
2. I searched for studies available through six databases of scholarly journals, published since 1992, focusing on the terms gender, women, female, sex, or, alternately, male and men, in the title or abstract. These six databases represented all electronic resources available through my university's academic library that index scholarly IS journals and conferences: ABI/Inform, ACM Digital Library, AISnet, EBSCo Business Source Premier, Emerald Online, and Science Direct. These sources cover all leading academic IS journals published in North America (e.g., *CACM*, *Database for Advances in IS*, *Decision Support Systems*, *ISR*, *Information & Management*, *Information and Organization*, *IRMJ*, *JASIS*, *Journal of CIS*, *Journal of MIS*, and *MIS Quarterly*) and Europe (*EJIS*, *ISJ*, *IT & People*, *Journal of IT*, *Journal of Strategic IS*). They also cover several leading conferences (AMCIS, ICIS, and ACM Special Interest Group on Computer Personnel). This set of databases, unfortunately, excludes papers from two other academic conferences: The ECIS conference (for which papers are not available electronically) and HICSS (for which conference papers are available electronically, but are not searchable). The conference proceedings of IFIP Working Group 8.2 were manually searched by scanning paper titles and abstracts. Studies that were initially published in conference proceedings and then later in a journal were counted just once.

Earnings of Women with Computer Science or Engineering College Majors

Catherine J. Weinberger
University of California Santa Barbara, USA

INTRODUCTION

This short article documents that women with college majors in computer science or engineering earn far more than other female college graduates[1]. This relationship is rarely discussed, as far more emphasis is usually placed on the difference in earnings between women and similarly educated men. While the existence of within-field gender pay gaps is important to monitor, these gaps do not necessarily deter women from entering a field. In fact, previous research finds that gender pay gaps tend to be relatively small among young college graduates with computer science or engineering majors, compared to the gender pay gaps in other fields (Weinberger, 1999, 2005; Weinberger & Joy, 2006). The combination of high average pay and low gender gaps in technical fields translates to particularly strong financial incentives for young women to enter these fields.

The statistics presented here are computed from nationally representative studies of United States (U.S.) college graduates. The first study is based on a sub-sample of 1990 U.S. Census respondents who also completed a detailed survey about their educational attainment in 1993, and were surveyed again in 1999. The second study is based on a representative group of 1992 U.S. high school seniors who were resurveyed in 1999, after most had completed their education. This study includes detailed information about each student, including 12th-grade standardized math test scores. Overall, the estimates presented here suggest that women with computer science or engineering college majors earn 30%-50% more than otherwise similar female college graduates.

BACKGROUND

High pay has been a consistent feature of the labor market for college graduates with majors in computer science or engineering. One government report describes the median salary of new college graduates in different fields for the years 1977, 1980, 1984, 1986, 1990 and 1993. In each of these years, computer science and engineering majors (combined) earned at least 35% more than the typical college graduate (NCES, 1998).

Most studies of gender, pay and college major focus on the fact that few women choose these remunerative college majors. The small proportion of women in mathematical college majors "explains" part of the gender differential in pay among college graduates (Brown & Corcoran, 1997; Weinberger 1998, 1999, 2001, 2005; Weinberger & Joy, 2006). However, a thorough analysis finds that, at age 32, only 20% of the overall gender pay gap is related to gender differences in either pre-college mathematics preparation or college major choices (Weinberger, 2001). Among college graduates, gender differences in college major explain a larger proportion—about one-fourth to one-half of the gender pay gap—with the proportion largest among young, recent labor market entrants (Weinberger 1998, 2005). The proportion of the gender pay gap attributable to differences in college major is larger in 1999 than it was for women the same age in 1989, probably because other factors contributing to the gender pay gap have diminished much more quickly (Weinberger, 2005).

WOMEN WITH COMPUTER SCIENCE OR ENGINEERING MAJORS

Statistics provided in Table 1 show that, at mid-life, women with computer science or engineering majors earn 30%-50% more than the average female college graduate.[2] This is true for representative samples of female college graduates aged 33-52 in either 1989 (Columns 1 and 2) or 1999 (Column 3).

Table 1. Average annual earnings by educational attainment, 1989 and 1999

	1989 Average Annual Earnings College Graduates Ages 33-52	1989 Average Annual Earnings Bachelors Level College Graduates Ages 33-52	1999 Average Annual Earnings Bachelors Level College Graduates Ages 33-52
Women Computer Science Majors	**$44,000**	**$43,000**	**$67,000**
(standard deviation)	(13,000)	(13,000)	(31,000)
Sample size	79	65	118
Women Engineering Majors	**$52,000**	**$48,000**	**$65,000**

R-Aquared	0.02	0.03	0.12

These data are from the National Center for Education Statistics National Education Longitudinal Study of 1988 eighth graders.
Sample restricted to white women college graduates working at least 35 hours per week, and at least 50 weeks per year in 1999.

Additional analysis finds that younger women (age 23-32) enjoy a similar advantage, with 1989 earnings \$37,000 for computer science/engineering majors (n=804) compared to \$28,000 for the typical college graduate.[3]

The longitudinal study of 1992 high school graduates provides an opportunity to make a more careful comparison between otherwise similar women. The results of ordinary least squares regressions displayed in Table 2 show that the large earnings advantage enjoyed by women with computer science or engineering degrees is robust to including controls for other observable variables. In this sample, women who majored in computer science or engineering earned 48% more than other female college graduates (Table 2, Column 1).[4] After controlling for 12th-grade math scores, the estimated advantage is still high (41%) (Table 2, Column 2).[5] The very small difference between Columns 1 and 2 results demonstrates that very little of the economic advantage to graduates with computer science or engineering majors is "explained" by this measure of pre-college academic preparation or ability that might be valued by the labor market regardless of the college major chosen. The estimated advantage does not change when controls are added for higher degrees earned, the number of hours worked per week and parents' educational attainment (Table 2, Column 3).[6] These regression results strongly suggest a large, causal relationship between women's choice of computer science or engineering college majors and later earnings.

FUTURE TRENDS

Remunerative careers in information technology fields have been around for a long time. Here is one of my favorite old quotes on the subject, from the 1956 book *The College Girl Looks Ahead to Her Career Opportunities*:

If you like doing the unusual and do not mind being the only woman in your college classroom or at work, and if you have the talent, engineering offers unusually high pay and a variety of interesting jobs in a shortage field. (Zapoleon, 1956, p. 227)

High pay has been a persistent feature of the labor market for women with technical training, and is likely to remain so.

CONCLUSION

The representation of women in computer science and engineering professions is not growing nearly as quickly as in other professional fields. Low pay is certainly not the reason. The statistical analysis presented here documents that both young and mid-career women with college majors in computer science or engineering earn 30%-50% more than otherwise similar female college graduates.

KEY TERMS

Gender Pay Gap: The percent difference in earnings between men and women with similar characteristics, estimated in an earnings regression.

Longitudinal Study: A study in which a group of people is followed over a period of time.

Observable Variables: Variables for which data are available.

Ordinary Least Squares Earnings Regression: Statistical estimation of a linear model of the relationship between the natural logarithm of each person's annual earnings and observable characteristics that tend to be correlated with earnings.

Representative Sample: A subset of a well-defined population, chosen at random from the full population.

Respondents: Individuals who participated in a survey.

Robust: The answer does not change if the question is framed a bit differently, or if the model is specified in a slightly different way.

Standardized Math Test: A math test for which the distribution of scores is well documented. The scores of individual students on these tests tend to be correlated with later educational attainment and labor market outcomes.

ENDNOTES

1 This material is based upon work supported by the National Science Foundation (NSF) under Grant No. 0120111. The use of NSF data does not imply NSF endorsement of the research methods or conclusions contained in this report. Any opinions, findings and conclusions or recommendations expressed in this material are those of the author and do not necessarily reflect the views of the NSF.

2 Based on annual earnings of full-time, year-round, white women workers, aged 33-52. (This group includes many women who did not work full-time continuously.)

3 Young women of color also enjoy this advantage, with 1989 average earnings of computer science/engineering majors $37,000 for Asian women (n=59), $35,000 for Hispanic women (n=39) and $33,000 for black women (n=115).

4 The earnings advantage is computed as the exponential of the estimated coefficient minus 1.

5 When this specification is estimated separately for Asian, Hispanic or black women, the estimated advantage to computer science/engineering majors is even higher for each of the three groups, ranging from 50%-65%. Relaxing the assumption of a linear relationship between math scores and earnings has virtually no effect on the coefficient of interest.

6 Parents' educational attainment is coded as the highest level attained by either parent. There are eight levels, including missing information for both parents.

An Economist's Perspective on Women in the IT Workforce[1]

Catherine J. Weinberger
University of California Santa Barbara, USA

INTRODUCTION

As a labor economist, my usual role in a discussion of women in the information technology (IT) workforce would be to establish the prevalence of gender differentials in outcomes. Elsewhere in this article, I address the question: Are women who invest time and money to acquire education and training in IT fields able to use their skills, and receive commensurate compensation, in the labor market? Because the answer to this question is simply "yes," I explore a second question in this article: Given that women with computer science and engineering college majors earn far more (on average) than other college-educated women, why do so few choose to pursue this career path? The answer to this question matters both because we continue to puzzle about why women tend to earn less than men and because (as argued so eloquently by Margolis & Fisher, 2002) the kinds of technologies that will be developed will depend on the life experiences and interests of our highly-trained IT professionals.

I approach this research by focusing on the college major choices of young women. While it is possible to enter IT careers through many different avenues, both occupational assignments and provision of on-the-job training result from complex interactions between individual workers and employers. In contrast, college major choices are typically far more unilateral, and tend to precede labor market entry. In my research, comparisons are made between women who choose to major in computer science or engineering and those who make other college major choices.

While it is true that women in computer science or engineering fields tend to earn less than men with the same college major, gender differentials in earnings are a fact of life along other career paths as well. For example, in the most recent year for which detailed information is available, the gender differential in earnings among college graduates in their 30s ranged from 15% to 20% in each of four other broad college major categories[2], compared to only 5% among both computer science and engineering majors (Weinberger & Joy, 2006).[3] The information most relevant to women making their career choices is how the earnings of women in IT careers compare to the earnings of other women. On this measure, college training in IT fields appears to be a sound investment: Women with computer science or engineering majors tend to earn 30%-50% more than otherwise similar female college graduates (Weinberger, in this volume).[4] The economic incentive for women to pursue these careers appears to be quite large. Based on this evidence, the barrier to women's entry is evidently not a lack of lucrative career opportunities.

Yet some kind of barrier clearly exists. Statistics available from the National Center for Education Statistics reveal that while the representation of women is now substantial among new college graduates in many previously male dominated fields, this is not true in either computer science or engineering fields.[5] In 1970, fewer than 10% of new bachelor's degree graduates in business, computer science, engineering or newly graduating doctors and lawyers, were women. Today, women and men are nearly equally represented among new graduates in business, law and medicine. In contrast, fewer than one-third of new computer science graduates, and an even smaller proportion of new engineers, are women. And there has been no obvious trend towards increasing representation of women in these fields in recent years. The research presented in the remainder of this article describes a survey of academically talented young women, asking questions designed to reveal what the operative barriers might be.

E

BACKGROUND

Opinions on the reasons for women's underrepresentation in science and engineering fields are varied. At one extreme, Gelernter (1999, pp. 11-12) opines that "The real explanation is obvious: Women are less drawn to science and engineering than men are … Women are *choosing* not to enter, presumably because they don't *want* to; presumably because (by and large) they don't like these fields or (on average) don't tend to excel in them, which is nearly the same thing." This perspective is not universal. Referring to the already highly selected population of M.I.T. science students she teaches, Hopkins (1999, p. 5) observes that "… although scientific talent and brilliance are equally distributed between the sexes, the career prospects for men and women are not equal." The contribution of social scientists to this debate is to take a step back from conclusions based on the people we happen to meet or presume to understand, and examine relationships between gender and career outcomes in randomly selected samples of well-defined populations.

Research based on representative samples of high school students followed to adulthood establish that, conditional on observable measures of academic talent and preparation, young women are only half as likely as young men to pursue science or engineering careers (Xie & Shauman, 2003).

Possible explanations for this difference abound. A growing body of evidence suggests that many women who intend to pursue higher education or careers in science, engineering or information technology fields find a less than welcoming atmosphere in both the university and the workplace (Keller, 1977; Tobias, 1978, 1990; Hall & Sandler, 1982; Gornick, 1983; Zuckerman, 1992; McIlwee & Robinson, 1992; Seymour & Hewitt, 1997; Schiebinger, 1999; Wyer, Barbercheck, Giesman, Ozturk, & Wayne, 2001). Economists tend to focus on explanations based on gender differences in the allocation of time between the labor market and childrearing, hypothesizing that women might prefer to prepare for careers in which labor force interruptions or reduced hours of work per week are less costly (Blakemore & Low, 1984; Polachek, 1978, 1981). A more recent economic analysis focuses on the possibility that women who make gender-atypical career choices might face social sanctions (Badgett & Folbre, 2003).

WHY DO WOMEN AVOID IT COLLEGE MAJORS?

Despite the proliferation of opinions and possible explanations, there is very little evidence on the actual tradeoffs considered by young women as they make their career choices. In a recent mail survey, I asked representative samples of college students at two very different institutions about their reasons for avoiding computer science, computer engineering, and electrical engineering, and other courses and careers. The format of the survey was a list of statements ("I would not choose the majors I have checked below because …" or "I would not choose the career paths I have checked below because …"), where each statement was followed by an alphabetical list of possible college majors or occupations. The results from the first institution are published elsewhere (Weinberger, 2004), while the very similar results for a group of surveyed students at the second institution are presented here, in Tables 1 and 2.

The sample of 195 women described here is representative of all female seniors at the University of Minnesota who were enrolled in a school other than the Institute of Technology and had enough credits to graduate at the time of the survey (Spring 2004).[6] While we focus here on reasons given for avoiding IT courses and careers, the survey was constructed to give no special emphasis to any particular career path. All choices were presented in a neutral way (alphabetically) and no reference was made to IT careers within the survey, cover letter or instructions.

Nonetheless, the women in this group were likely to say that they would avoid IT courses and careers for each of several reasons. The patterns of responses are very similar to those obtained in all three samples examined previously: women in majors chosen by more women than men, women with very high math SAT scores in the same set of majors, and women in the business economics major, all of whom were seniors at University of California—Santa Barbara (Weinberger, 2004). The sample described

Table 1. Proportion indicating "I would not choose the majors I have checked below because …"

"… the work would not be socially useful"	0.2	**0.3**	**0.3**	**0.2**	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.2
"… it would be difficult to combine these careers with raising a family"	0.1	**0.1**	**0.1**	**0.1**	0.4	0.1	0.2	0.1	0.1	0.5	0.0	0.1
"… I wouldn't expect the workplace atmosphere to be welcoming to me"	0.1	**0.4**	**0.3**	**0.4**	0.1	0.0	0.0	0.0	0.0	0.2	0.0	0.2

here is different because it is larger and is representative of the entire graduating class of young women at an institution with nearly every possible college major available.

As in the previous samples, almost none of the women in this sample were concerned that they would not be able to find a job that paid well if they choose an IT college major or occupation. These students correctly perceive that computer and electrical engineering jobs are remunerative. There is also little support for other explanations suggested by economic models: Very few women are concerned with social sanctions for choosing IT majors, or express concern that IT careers would require working long hours per week or be difficult to combine with raising a family. In fact, the career paths that were perceived as difficult for mothers (lawyer and doctor) are exactly those in which women have become increasingly well represented in recent years. This is clearly not the barrier to women's entry into IT careers. There was some support for the notion that IT careers are incompatible with taking time out of the labor market altogether (as opposed to working, at least part-time, while parenting), but the surveyed students evidently did not expect this to make IT careers difficult to combine with parenting.

In contrast to the low levels of concern about these economic factors, 30%-40% of the women indicated an expectation that the classroom and workplace atmosphere in IT would not be welcoming to women, or to them personally. Similar levels of concern were reported for each of the three samples in Weinberger (2004), including the sample of women with very high math SAT scores. Concern about climate was not highly correlated with lack of interest in IT careers in any of the samples. Although not the majority of women, it is striking to find higher levels of concern about climate in IT than in medicine, law or finance.

Previous results that IT courses are considered to be both more time-consuming and more difficult than other college courses were also replicated here. One of the most surprising earlier findings is that young women were more likely to indicate that "the coursework required would be too difficult" when asked about IT careers than when asked about a career as a surgeon. Finding it incredible that a bachelor's degree in computer science could be perceived as more difficult than training to be a surgeon, I rephrased the question for the new survey. The question (and responses) were similar in the first section of the survey. As before, 50%-60% of students checked computer engineering, computer science and electrical engineering when prompted with: "I would not choose the majors I have checked below because the courses are too difficult." In the second section of the survey, the prompt: "I would not choose the career paths I have checked below because the coursework required would be too difficult" was replaced in this version by "…because I could not pass the courses." This change in wording was chosen to eliminate those who simply believed the courses were too difficult to bother with, given their level of interest. As expected, students tended to be less likely to believe they would fail than to think the courses were too difficult. However, the surprising result persisted. Forty percent of the women at this selective university believed that they could not pass the courses required for careers in computer engineering, computer programming or electrical engineering. Again, this coursework was perceived as more difficult than that required to become a surgeon.[7]

The question for which the change of venue seems to have had the largest effect is "I would not choose the majors I have checked below because I would not be prepared to do socially useful work after graduation." More women were concerned about this in the Minnesota sample, with 20%-30% indicating this concern about IT college majors. For this version of the survey, the question "I would not choose the career paths I have checked below because the work would not be meaningful or socially useful" was divided into two separate questions ("… would not be meaningful to me" and "… would not be socially useful"). Again, 20%-30% were concerned about the social usefulness of IT careers, but fully 70%-80% indicated that this work would not be personally meaningful.

FUTURE TRENDS

It seems that a vast majority of the women in the sample (90%) would agree with Professor Gelernter that they would not be interested in the courses and would not enjoy the work associated with courses or careers in computer engineering, computer science or electrical engineering. This finding suggests it is vital that we try to understand the mechanisms underlying interest formation if we are to understand the processes leading to this self-selected segregation.[8] It is also important to learn whether it is something intrinsic to these technical subjects, or only the evolved culture surrounding them, that young women find uninviting.[9] This line of inquiry is, in fact, particularly important if it is the case that women have different interests and life experiences than men. For this is exactly the circumstance in which it is important that women's voices be heard when decisions are made about which potential technologies can be developed to best serve the public good.

Just as the federal government sponsors research to understand the fundamentals of good nutrition and informational campaigns to encourage people to eat more fresh vegetables, there is a role for government to support research and policy to foster healthy professional development. And just as my grandmother and mother selected recipes from other cultures that made vegetables more appealing and healthier, there is a role for families here as well. As a research community, our role is to provide reliable information to young people who have the capability to contribute to society in ways they might not have imagined for themselves.

CONCLUSION

Economic considerations do not appear to be the operative barrier preventing surveyed women from choosing college majors or careers in computer science, computer engineering or electrical engineering. Instead, female college students express lack of interest, expectations of not being welcome and seemingly inflated evaluations of the difficulty of college coursework in these fields. These findings point to future research on the process of interest formation, efforts to improve (or change perceptions of) classroom and workplace climates for women, and systematic evaluation of the actual and perceived difficulty of teaching technical subjects to academically high-achieving women. The potential benefits include a future pool of talented, well-trained IT decision makers with a wider range of perspectives than are currently represented.

KEY TERMS

Earnings Regression: Statistical estimation of a linear model of the relationship between the natural logarithm of each person's annual earnings and observable characteristics that tend to be correlated with earnings.

Gender Differential in Earnings: The percent difference in average annual earnings between men and women with similar characteristics, estimated in an earnings regression.

Highly Selected: A group of people not representative of the entire population, because entry into the group is contingent on stringent selection criteria.

Math SAT Score: The score on a test widely used for college admissions. This score tends to be correlated with the probability of entry into training for technical fields.

Occupational Assignments: The outcome of a process by which individuals are matched with jobs.

Remunerative: Pay well.

Representative Sample: A subset of a well-defined population, chosen at random from the full population.

ENDNOTES

1 I thank Insook Cho for excellent research assistance. This material is based upon work supported by the National Science Foundation (NSF) under Grant No. 0120111. The use of NSF data does not imply NSF endorsement of

the research methods or conclusions contained in this report. Any opinions, findings and conclusions or recommendations expressed in this material are those of the author and do not necessarily reflect the views of the NSF.

2 The categories were Business, Social Science/Humanities, Math/Science and Education. These earnings regressions controlled for differences in hours worked per week, full- and part-time work experience, geographic region, parents' educational attainment and detailed college major within each category. Sample sizes ranged from 700 to 3,500.

3 To read more about gender differentials in pay among the highly educated, see Brown and Corcoran (1997), Weinberger (1998, 1999, 2001, 2005).

4 This brief piece cannot adequately address interactions between college major choices, race/ethnicity and labor market outcomes. For a thorough analysis of this question, see Weinberger and Joy (2006).

5 See http://nces.ed.gov/edstats/

6 Mail surveys were sent to 20% of all second-semester seniors. The response rate for women was just more than 40%. The women described here were enrolled in the Colleges of Liberal Arts (n=108), Biological Sciences (n=12), Management (n=13), Education (n=17), Nursing (n=24) and the college formerly known as Home Economics (n=21). Seniors were sampled because this survey is part of the larger College and Career Choices Study, designed to follow these students into the labor market.

7 As in Weinberger (2004), the corresponding sample of men perceived the coursework required to become a surgeon as more difficult than that required for any of these IT career paths.

8 Research on this topic by Jaquelynne Eccles is in progress.

9 See Seymour & Hewitt (1997), and Margolis and Fisher (2002), for thoughtful treatment of this subject.

E

E-Empowerment through Strengthening Women's Policy Issues via the Internet

Tanja Carstensen
Hamburg University of Technology, Germany

Gabriele Winker
Hamburg University of Technology, Germany

INTRODUCTION

Both Internet studies and women's and gender studies formulated various hopes and fears for the effects of the Internet on gender relations at an early point. Whereas some scholars saw it as a male domain, others pinned hopes for overcoming dichotomous gender constructions to the new technology. The Internet was also seen as an opportunity to network women's policy activists and to strengthen women's policy issues from the very beginning.

There have, however, been few studies of how women specifically use the Internet to further feminist issues. This article addresses this question of Internet use in women's policy networks based on an empirical study, which examined the democratizing use of the Internet for German women's networks. We start off by signifying the importance of the Internet within the developments of the women's movement and giving an overview of the existing research findings. We then analyze the use of the Internet within women's policy networks, using the three dimensions "information", "interaction," and "political action". We wind up the article by outlining an idea that could be used to better concentrate and structure existing Internet services, possibly strengthening women's public political spaces.

BACKGROUND

From its very beginnings, the Internet has been a space for feminists to network and hold discussions: Professional organizations of and for women use the Internet to call attention to women's underrepresentation in technical and scientific occupational areas and to publish background material on the gender-hierarchical division of labor. Women suffering from specific illnesses or with experience of violence can find help and opportunities for exchange via virtual self-help organizations. Women network on an international level via mailing lists on various subjects, such as development policy or breaches of human rights. Cyberfeminists deconstruct the social category of woman with subversive irony and humor, and experiment with new identities in a variety of ways. These and many other pieces of the jigsaw fit together to indicate the broad-based professional and voluntary work of diverse women on the Internet, who are often also active outside of the net in informal networks or established organizations. The Internet appears to offer a wide variety of potentials for women's policy activities.

This diversity cannot, however, be taken for granted, as women's policy activists have been under increasing pressure to justify their activities and standpoints since the last decade of the 20th century. Whereas discrimination against women as a whole was undisputed within the women's movements of the industrialized nations in the 1970s, this view is no longer universally accepted today.

Two developments in particular are behind this change:

- In the industrialized nations, an increasing number of women are being integrated into the labor market. Young women and men have reached an equalized educational level to a major extent, lifestyles are becoming increasingly pluralized, and young women frequently take the existence of equality for granted in these countries.

- Simultaneously, the theoretical discussion on the category of gender has changed direction. Since the mid-1980s, discussion has clearly refocused on the differences *between* women. The call to integrate further axes of inequality alongside gender—such as class, race, and sexuality—that accompanies this development has made it more difficult to justify and realize women's policy activities, despite leading to important new insights.

In this situation, which has led to feelings of uncertainty among those interested and active in women's policy, the Internet provides new spaces for experimentation, which women's policy activists from various types of organizations, associations, and networks use for their very diverse concerns. The new medium appears to be ideally suited to today's age of new disorder, characterized by multiple experiences of discrimination that cannot always be precisely assigned to a specific group.

LITERATURE REVIEW

Since the 1990s, gender and Internet studies have addressed the extent to which the Internet as a technology is a relevant to women or gender and can set gender hierarchies in motion. We can distinguish three positions:

1. **The Internet as a Male Domain:** One significant thread of research on the subject of Internet and gender aims to reveal male dominance on the net. Early studies in particular on access, gender-specific matters of use and communication, and the content of the net come to the conclusion that the Internet is predominately androcentric and, like the "real world", steeped with inequalities and power relationships (Herring, 1996; Spender, 1995). More recent studies, however, show that gender-specific differences have less influence on the digital divide than differences in the factors of age, education and profession (DiMaggio & Hargittai, 2001; Winker, 2005).
2. **The Internet as a Space for Deconstructing Dichotomous Gender Conceptions:** At the same time, feminists have developed utopian visions of a world beyond dichotomous concepts of gender. The possibility of "gender swapping" on the Internet prompted hopes that identities could be constructed in diverse ways (Bruckman, 1993; Turkle, 1995). Cyberfeminists retell the story of technology and gender, interpreting the net as feminine (Plant, 1997), and experiment with gender stereotypes in a playful, joyful, and artistic way (Hawthorne & Klein, 1999).
3. **The Internet as an Opportunity for Women's Policy:** The third thread in the feminist debate on the Internet consists of expectations that women could make use of the Internet to further their own issues and interests. Feminists see new possibilities for networking common interests and for publicizing these subjects (Consalvo & Paasonen, 2002). Feminist discourses also express expectations of building solidarity and communities (Shade, 2002) and worldwide access to diverse knowledge (Floyd, Kelkar, Klein-Franke, Kramarae, & Limpangog, 2002; Harcourt, 1999). However, Shade (2002) and others warn women not to overestimate the Internet. She points out that, although the Internet does offer a variety of opportunities for women's participation in many areas of society, very many women (and men) are also excluded from the net due to both technical requirements (knowledge and availability of hardware and software, lack of infrastructure such as telephone lines and connections in "third world" countries) and socio-economic conditions.

E-EMPOWERMENT

Prognoses, hopes and fears have dominated research to date. There have been very few systematic surveys on how the Internet's possibilities and the new scope for action emerging for political work are utilized and adopted in the context of gender or women's policy issues. The empirical study "E-Empowerment: Use of the Internet in Women's Policy Networks" tackles this research gap, asking to what extent the new medium is used by women's policy activists in Germany for empowerment, in the sense of strengthening their own power and influence.

The study uses various methods:

- Analyses of the Internet presences of 200 German women's networks
- Qualitative interviews with 20 women's policy activists on their use of the Web
- Log-file analyses regarding individual search strategies and the findability of women's networks
- Future workshop conducted online with female Internet experts, on possibilities of networking women's policy organizations via the Internet in the future.

The study is limited to German women's networks and was carried out between 2001 and 2004. It was funded by the German Federal Ministry of Education and Research. As well as analyzing the existing situation regarding the Internet in women's policy networks, it developed practice-related suggestions for designing Internet services for women's policy networks that can be used by as many women as possible and support their political participation (Schachtner & Winker, 2005).

The terms *women's policy networks* or *political women's networks* are used as generic terms for various types of groups of women, regardless of their specific form of organization—from women's associations and political parties to autonomous women's projects or self-help groups with informal organizational forms.

The term *empowerment*, first coined by Rappaport (1984), is closely linked to the U.S. civil and women's rights movements. Through cooperation, people in marginal positions can use and develop their own sources of power to gain greater self-determination and control over their own lives. Empowerment also refers to collective political self-organization, enabling disadvantaged sections of the population to articulate their interests, participate in political processes and gain power. The concept of empowerment not only criticizes existing power relationships, but also demonstrates perspectives for change.

Strengthening Subaltern Counterpublics via the Internet

In order to systematically examine the use of the Internet for women's political interests and the significance of women's policy activities on the Internet, we must compare the objectives and interests of women's policy networks with the functions of the Internet.

Nancy Fraser (1997) describes political women's networks as subaltern counterpublics. According to Fraser, subaltern counterpublics are, firstly, "parallel discursive arenas where members of subordinated social groups invent and circulate counter discourses, which in turn permit them to formulate oppositional interpretations of their identities, interests, and needs" (p. 81). Secondly, Fraser describes subaltern counterpublics as functioning as their participants' own spaces, enabling withdrawal and regrouping, and, thirdly, as capable of changing socio-political reality by influencing discourses and norms in larger, hegemonic publics.

The Internet can further the three aims of subaltern counterpublics named in the previous paragraphs. These objectives can be classified into the three dimensions of "information", "interaction", and "political action". Figure 1 shows how women's policy issues can be strengthened via the Internet.

Figure 1. Strengthening subaltern counterpublics through women's policy Internet presences

Aims of women's policy networks (Fraser, 1997)		
Development of oppositional interpretations of identities and interests	Creation of spaces that allow withdrawal and re-groupment	Representation of interests outside their own spaces and exerting influence in larger arenas
↓	↓	↓
Internet functions for promoting the aims		
Information	Interaction	Political Action
Publishing orientation knowledge Findability via search functions and links Cooperative provision of information	Forums and chatrooms for exchanging and developing problem-solving skills	Preparing and carrying out political activities on the net: - planning actions - signature lists - online polls

Information

Women's policy networks address social problems. Described in terms of Fraser's analytical framework, these networks develop interpretations of identities and interests in opposition to the hegemonic discourse and offer new frameworks and meanings for social reality.

On the net, information can be made transparent and accessible extremely quickly. By using and appropriating the Internet, women's policy networks can publish knowledge, which can then reach a larger circle of interested women. Feminist discourses can be made accessible to a wider public, and possibilities for finding this information can be improved by search functions and links. Networks can refer to each other and bundle their resources. Finally, they can offer information co-operatively, (i.e., by using tools in which every network can enter information on a common platform).

Interaction

At the same time, women's policy networks have the function of creating spaces for withdrawal and regrouping and using them to communicate about their issues and interests outside the hegemonic discourse. Within these spaces, they consult and encourage each other and exchange experiences.

Internet services such as forums and chatrooms simplify communicative exchange between women's policy activists. Such services can improve the flow of information between women, support discussions, and act as a means to develop joint solutions to problems. Further, they allow users to question hegemonic norms or create new norms. Fraser's spaces for practicing political activities can be created in interactive forums and chatrooms; the results of these interactions in Internet-based forums can then be transferred into larger arenas. Communication on the Internet is a valuable addition to traditional forms of discussion, due to its greater flexibility with regard to time and space.

Political Action

Finally, aside from addressing problems within society and communicating on these problems in small groups, the goal of subaltern counterpublics is to represent their interests outside their own spaces. Fraser describes this as their main emancipative potential, because they are able to change political reality by influencing discourses and norms in larger public spaces.

The new technologies offer opportunities for larger groups to participate in political activities. The Internet can be used as a platform to plan joint political actions and to call for participation (e.g., signature lists). In this way, more effective and outwardly perceivable publics can arise.

EMPIRICAL FINDINGS

The research project "E-Empowerment. Use of the Internet in Women's Policy Networks" studied these functions in the three areas of "information", "interaction", and "political action", using the research methods described above.

Information

Our findings indicate that the clear focus of the Web sites of German women's networks is currently on providing information. The networks present themselves on the Web sites, give information on upcoming events, and provide background material on their subjects. At the same time, interviews with women's policy activists confirm that these women use the Internet primarily for searching for information. Women's policy experts use the net to search for academic texts, information on current political discussions and specialized women's policy subjects from their working areas, as well as for organizational support for their everyday tasks.

Thus, the women's policy networks use the medium of the Internet in the same way as they use the traditional media, especially for the purpose of public relations. A wide spectrum of specialized knowledge and a large amount of information is made accessible to a large audience via the Internet. A potentially large group of users therefore has the possibility of principally improved orientation. Many different subjects related to women's work and lives are made public by taking up the problems of society on the net. This certainly supports and strengthens the already existing subaltern publics.

However, the information is currently poorly linked according to subject areas. Women's networks are also frequently difficult to locate on the Web. The wide range of subjects resulting from the many different approaches among the networks is thus not made accessible to all interested parties via the Internet, but instead often only to insiders. This means that the information made available on the net is only used to a sub-optimal extent, and only finds its way into the process of political opinion forming in fragmentary form.

Our study of search behavior on the Internet used log-file protocols, indicating that the most frequently used approach to searching that is keyword searches via a search engine is time-consuming and often brings limited success. Information relevant in a women's policy context has to be gathered from all the far-flung corners of the Web, at great effort. Women's policy networks are thus at risk of remaining enclaves and receiving little attention, as unconnected points in the enormous realm of cyberspace.

Interaction

In comparison to the information services—which could be improved but do at least exist—communication services with the aim of entering into lively discussion with the users on further activities are still distinctly underrepresented. The Internet is very rarely used as an instrument of interactive opinion forming. The women interviewed in the course of our study stated lack of time as the primary reason for this. They only integrate e-mail into everyday life as a matter of course. Online communities that have arisen via the net itself form an exception to this general rule, for example the Webgrrls. For these groups, interaction via the net is of decisive importance, as they do not have meeting places outside of the Web at their disposal to the same extent as networks that came about independently of the Internet.

However, in general, exploitation of the Internet's interactive potential is still in its infancy in Germany.

Political Action

Similarly, very few visible women's political activities such as petitions, online polls, or public campaigns are currently being developed on the net. Neither are there any joint, inter-organizational projects in the women's policy arena, such as public conferences or future workshops, which are jointly prepared and implemented on the Web.

To summarize, we can state that, in Germany, the Internet is primarily used by the women's networks investigated as a one-way information channel, without exploitation of the medium's interactive aspects. Their use of the networking potential of the Web is also limited. Women's organizations do not make full use of the Internet's basic potential as an information *and* communication medium.

FUTURE TRENDS

New processes must be developed to enable feminists to virtually structure and link existing information and interaction services, in order to form effective counterpublics using the technical potential of the Internet. The portals increasingly arising on the Internet are one possibility for gathering information from a variety of sources. However, portals are often financed by government or private enterprise, and thus do not necessarily provide support for subaltern counterpublics.

This aim can be better achieved using the concept of "virtual neighborhoods" (Taube & Winker, 2005). Grouping all interested women's policy networks into a virtual neighborhood means a wide range of information can be found quickly and precisely, via new types of search functions. In addition, visualizing the relationships within a virtual neighborhood illustrates content-related, regional, or other intertwined links and connections, making the closeness or distance between networks visible. Content can be structured by a problem-specific thesaurus.

Virtual neighborhoods with varying emphases can give activists an immediate overview of the varied informative and interactive projects on offer. This is particularly important for political women's networks, as their activists have fewer material and time resources, due to the gender-hierarchical division of labor and increasing everyday demands through the blurring of boundaries between work and all areas of life (Winker & Carstensen, 2004).

CONCLUSION

Women's policy activists and scholars of gender and Internet studies face the task of realizing virtual neighborhoods, and other concepts with which subaltern counterpublics can be promoted on the net, in women's political contexts in the future. Such information technology-based support can be used to develop and strengthen individual power, and to gather resources for resistance against social oppression and discrimination of identities, very much in the sense of the empowerment concept. These opportunities for e-empowerment are still only beginning to come into use, but initial successes are already visible and making their own contribution to strengthening women's political issues.

KEY TERMS

E-Empowerment: Promoting empowerment processes via the Internet and/or computer-supported networks.

Empowerment: Gaining influence and power to control one's own life and living conditions and to participate in political processes. The aim of the concept is collective self-organization of disadvantaged groups.

Online Community: Location on the Internet where people with similar interests meet regularly, focusing on general communication and the problem-related exchange of information.

Portal: A collection of information and services from multiple sources under one Web address, provided by a central editorial body.

Subaltern Counterpublics: Subaltern counterpublics are public spaces of societal groups that are excluded from the hegemonic public and the dominant discourse (Fraser, 1997).

Virtual Neighborhood: Structure and grouping of thematically related Web presences in an independent location on the WWW, providing search options by means of a unified thesaurus and a visualization of content-related, regional, or other relationships.

Women's Policy Networks: Groups of women, regardless of their specific organizational form—women's associations, political parties, autonomous women's projects, or self-help groups.

Employment Arrangements, Need Profiles, and Gender

Thomas W. Ferratt
University of Dayton, USA

Harvey G. Enns
University of Dayton, USA

Jayesh Prasad
University of Dayton, USA

INTRODUCTION

Information technology has become increasingly pervasive in the products and services of organizations. Similarly, IT has become increasingly essential in supporting work at all organizational levels. These forces have increased the demand for the work that IT professionals perform. At the same time, managerial initiatives for increased efficiencies have led to increases in outsourcing and downsizing. As a result, the IT human-resource (HR) strategies that organizations employ vary (Agarwal & Ferratt, 1999).

Different IT HR strategies are implemented through differences in HR practices, such as differences in employment guarantees, career development, and the flexibility allowed in scheduling one's work. These differences in IT HR practices result in different employment arrangements for IT professionals. According to fit theory and research (Kristof, 1996; Kristof-Brown, Zimmerman, & Johnson, 2005), the fit between what the organization supplies and what the IT professional needs influences attitudinal and behavioral outcomes, such as satisfaction, turnover, performance, and helping behavior. If an organization has a common set of IT HR practices for all IT professionals, greater fit and the organizationally desired outcomes associated with greater fit will most likely occur if all IT professionals have a common set of needs.

A question that arises is whether all IT professionals do have a common set of needs. If subgroups of IT professionals have different needs but an organization has a common set of IT HR practices for all IT professionals, that organization may not appeal to a valuable pool of potential employees. Recent analysis of the composition of the U.S. workforce shows that women are underrepresented in IT (Information Technology Association of America [ITAA], 2003, 2005a, 2005b). The percentage of women in the professional and management ranks of the IT workforce was 24.9% in 2004; the percentage in all IT workforce positions, including lower level administrative job categories, was 32.4%. In comparison, the percentage of women in the overall workforce was 46.5%. One potential explanation for this underrepresentation could be that organizations do not provide employment arrangements that address the needs of women as well as they do the needs of men and, thus, are unable to attract and retain IT professionals equally from these gender subgroups.

Research Hypothesis

Given the underrepresentation of women in IT and the potential explanation above, this research is guided by the following research question: Are women and men IT professionals homogeneous with respect to the needs they seek to satisfy in their employment arrangements? If organizations provide all their IT professionals, regardless of gender, with the same employment arrangement, and the answer to the research question is negative, that would suggest that organizations should design employment arrangements to be more inclusive of women's needs. Thus, rejecting the following null hypothesis would provide evidence that begins to build support for the explanation and potential solutions.

H_0: Women and men IT professionals have no differences in the needs they seek to satisfy in their employment arrangements.

BACKGROUND

A number of characteristics have been identified as being especially relevant for differentiating between employment arrangements (Ang & Slaughter, 2000; Kraut, Steinfield, Chan, Butler, & Hoag, 1999; Rousseau, 1995). Eleven characteristics, listed below, are included in this study. The importance of each of those characteristics is used to identify need profiles that describe different types of IT professionals based on the types presented in Enns, Ferratt, and Prasad (in press). These types are based on three broad need categories that employment arrangements may satisfy. Specifically, these need categories consist of security, achievement, and flexibility. The employment-arrangement characteristics that may satisfy a specific need category are the following:

- **Security:** (a) Job security, (b) pay, and (c) benefits
- **Achievement:** (a) Career-development opportunities, (b) the specificity of performance requirements, (c) discretion in choosing what work one does (work-choice discretion), (d) recognition, and (e) social interaction and support
- **Flexibility:** (a) Discretion in choosing when to work (schedule discretion), (b) discretion in choosing where to work (location discretion), and (c) travel discretion

Prasad, Ferratt, and Enns (2005) developed and validated a categorization procedure that places most IT professionals (i.e., approximately 80%) into one of three need profiles: high maintenance, lifestyle, and committed. The high-maintenance profile is characterized by greater needs for achievement and flexibility and a lower need for security. The lifestyle profile is characterized by greater needs for security and flexibility and a lower need for achievement. The committed profile is characterized by greater needs for security and achievement and a lower need for flexibility.

Rather than using need profiles, we could just compare women to men on each specific need. The latter analysis would assume that the mean value for a specific need within a gender group would represent all members of that group equally well, whereas the former analysis would allow for the potential that differences in a specific need exist within each gender group.

Prior research by Igbaria, Greenhaus, and Parasuraman (1991) suggests that the analysis of need profiles is a more appropriate approach for testing the research hypothesis. Although they did not measure needs associated with employment arrangements, they found significant differences in the distribution of women and men across eight career orientations (e.g., DeLong, 1982; Schein, 1987). They found that career orientations within gender groups were distributed across these eight career orientations; that is, women were not all the same in career orientation, nor were men. The percentage of women across the eight career orientations ranged from 4% (for the career orientation of entrepreneurship) to 22% (for the managerial career orientation), whereas the percentage of men ranged from 5% (entrepreneurship) to 27% (managerial). The percentages of women and men within a given career orientation were typically 20% and 80%. Of specific note were their findings for one of the career orientations, namely, lifestyle integration: a desire to develop a lifestyle that integrates family concerns, career concerns, and concerns for self-development. A greater percentage of women and a lower percentage of men than typical had this career orientation (39% vs. 20% for women; 61% vs. 80% for men). Similarly, the percentage of women with this career orientation (21%) was much higher than the percentage of men (8%). Others have noted that balancing work-family issues is a key factor contributing to the underrepresentation of women in the IT workforce (e.g., see Quesenberry, Trauth, & Morgan, in press).

Given the results of Igbaria et al. (1991), we expect that differences in needs related to employment arrangements exist among women and among men. Thus, the use of the three need profiles will allow us to test that expectation. If differences in needs related to employment arrangements exist between women and men IT professionals, we also expect that the genders would not be distributed across these need profiles in the same percentages. Given the recency of the conceptualization of these need profiles and, thus, the lack of prior empirical investigation of gender differences in these need profiles, we do not have prior expectations about what differences may exist.

METHODOLOGY

Sample

We surveyed members of a national IT professional organization. Of the organization's 3,369 members, 255 respondents voluntarily answered a Web-based survey that had a standard set of questions plus an optional set of survey questions relevant for this research. Of these respondents, 187 (73.4%) reported they were men and 68 (26.7%) women. Demographics of age, tenure with the current organization, and years worked in a full-time IT position are reported in Table 1.

Measures of Importance of Employment Characteristics

The importance of each of the 11 employment-arrangement characteristics was measured on a five-point scale (where 1 was *low importance* and 5 was *high importance*) using the same 29 items as Prasad et al. (2005). The scale value was determined by averaging the respondent's rating of how important it was that her or his preference for an item measuring that characteristic be met. An example of an item used to determine the importance of social interaction and support is "The degree of social acceptance by the people I work with." The means, standard deviations (S.D.), and reliabilities of each of the 11 importance scales are reported in Table 1.

Confirmatory factor analysis shows that the expected 11 factors emerge when analyzing the 29 items. Twenty-five items load as expected, but there are anomalies with four items. The two items measuring the importance of benefits load higher on the factor comprised of the items measuring the importance of pay. One of the items measuring the importance of career-development opportunities loads higher on the factor comprised of the items for measuring the importance of work-choice discre-

tion. For all three of these items, the next highest loadings are on the appropriate factor. The fourth item, extent of the supervisor's concern, loads highly on a factor comprised of items measuring the importance of recognition. The addition of this item to the recognition scale would increase the reliability of recognition slightly from 0.876 to 0.888, while its deletion from the expected social interaction and support scale would barely lower its reliability from 0.831 to 0.830. These analyses and the reliabilities of the 11 importance scales shown in Table 1 indicate that the 11 original importance scales have adequate discriminant and convergent validity for subsequent analyses with this sample. Therefore, we use the original scales without modification.

Analysis

Since needs that IT professionals seek to satisfy are conceptualized as need profiles, testing the research hypothesis involves categorizing each IT professional into a need profile and determining whether women and men have significantly different percentages in each profile. We used the classification procedure based on Enns et al. (in press) and validated by Prasad et al. (2005) to categorize respondents into one of the three need profiles (or into an unclassified need profile if the respondent does not fit into one of the three). This procedure uses the relative importance of one item from each of the three broad need categories, as explained below. Although the procedure is not intended to be exhaustive, the validation study suggests that it will categorize about 80% of IT professionals into one of the three need profiles.

Specifically, for each respondent, we ranked the scores on all 11 importance scales (with 1 being highest and 11 lowest). We placed a respondent into (a) the high-maintenance need profile if the rank of job security was greater than or equal to 4.5, career-development opportunities was less than 9, and schedule discretion was less than 9, (b) the lifestyle need profile if the rank of job security was less than 4.5, career-development opportunities was greater than 3, and schedule discretion was less than or equal to 7, or (c) the committed need profile if the rank of job security was less than 4.5, career-development opportunities was less than 9, and schedule discretion was greater than 7.

To test the hypothesis, a chi-square test was used on the number of women and men classified into each of the three need profiles. Additional comparisons of women and men on the importance of employment-arrangement characteristics and demographics within the three need profiles and the unclassified need profile were also conducted using an analysis of variance.

RESULTS AND DISCUSSION

If we were to examine gender differences by focusing on the means of specific needs for each gender, the significant differences shown in Table 1 would lead us to conclude that women and men have different needs related to employment arrangements. Controlling for age, organizational tenure, and years of experience in IT still results in significant gender differences in the importance of benefits and schedule discretion. However, as discussed earlier, the analysis in Table 1 is based on the assumption that all women are alike and all men are alike. The more appropriate test is to examine gender differences using need profiles.

The three need profiles account for 79% of the respondents (201 of 255). Table 2 shows the distribution of women and men across these profiles. The null hypothesis that men and women have no differences in their need profiles cannot be rejected (chi-square=2.78, degrees of freedom=2, significance=0.250). Thus, these results suggest that the distribution of need profiles that the majority of women IT professionals bring to an employment arrangement is no different than the distribution of need profiles of the majority of men.

These results also show that each gender group has sizable subgroups with different need profiles,

Table 2. Gender by need profile

	Men	Women	Total
Need Profile	*N* (%)[a]	*N* (%)	*N*
High maintenance	45 (68.2)	21 (31.8)	66
Lifestyle	37 (68.5)	17 (31.5)	54
Committed	64 (79.0)	17 (21.0)	81
Total	146 (72.6)	55 (27.4)	201

Note: [a] Percent is the number of men (or women) within a need profile divided by the total number within the profile

consistent with an individual-differences perspective (Trauth, 2002; Trauth, Quesenberry, & Morgan, 2004). No one need profile is dominant for women or for men. Given the results in Table 2, the percentage of women with a given need profile ranges from 31 to 38% (e.g., 17/55=31% and 21/55=38%), and the percentage of men with a given profile ranges from 25 to 44% (e.g., 37/146=25% and 64/146=44%). These results indicate that there are differences among women and among men; that is, not all women IT professionals have the same needs, nor do all men.

The importance of employment-arrangement characteristics and the demographics for each of the three need profiles are shown in Table 3. Significant differences found by an analysis of variance are consistent with the definitions of the profiles. Beyond the results shown in Table 3, there are no significant gender differences on employment-arrangement characteristics within any of the need profiles. The only significant differences (p<0.05) in the demographics of women and men are in the high-maintenance need profile: Women are younger than men (45.7 vs. 51.7 years) and have worked in IT for a shorter period of time (16.1 vs. 23.2 years).

FUTURE RESEARCH

Although the respondents come from a national sample, they are not a random sample of all IT professionals. Thus, our results may not generalize to the population. Studies with other samples need to replicate our findings to increase confidence that the results generalize.

We examined one of the two key elements of fit between IT professionals and the employment arrangements provided by their employers. Specifically, we examined the needs that IT professionals bring to an employment arrangement. We did not examine the supplies provided by the employment arrangement through the IT HR practices of the employer. Future research into the effects on women and men of employment arrangements designed to satisfy the three need profiles would be appropriate.

One additional limitation suggesting a direction for future research is that about 20% of our sample of IT professionals was not classified into a need profile. This group of respondents (13 women, 40 men) has significant differences by gender. The women are younger than the men and have worked in IT for a shorter period of time (see Table 4). Further analysis of variance shows that there are

significant differences in the importance of job security, benefits, and travel discretion, with women rating them as more important. Controlling for age, organizational tenure, and years of experience in IT still results in a significant gender difference in the importance of travel discretion. Are there additional need profiles that would account for these apparent gender differences that remain after taking the three need profiles into account? Future research on those in this unclassified need profile could help us address this question and better understand this residual group of women and men IT professionals.

CONCLUSION

Based on investigating the need profiles of IT professionals within the context of fit theory, we conclude that a single employment arrangement is unlikely to meet the needs of the majority of women or men. Furthermore, an employment arrangement tailored to a specific need profile should fit equally well with both women and men IT professionals who have that need profile. Going further, designing an employment arrangement that is more inclusive of the needs of a specific gender does not make as much sense as designing an employment arrangement based on the specific need profiles of IT professionals. Our findings provide a compelling basis for additional empirical research to confirm the validity of these conclusions.

KEY TERMS

Committed Need Profile: A need profile characterized by greater needs for security and achievement and a lower need for flexibility.

Employment Arrangement: What an organization supplies to an IT professional through the set of HR practices it implements.

Employment-Arrangement Characteristic: A descriptor of what an organization supplies through its IT HR practices, for example, job security, pay, benefits, career-development opportunities, the specificity of performance requirements, work-choice discretion, recognition, social interaction and support, schedule discretion, location discretion, and travel discretion.

Fit: A condition that occurs when an individual's needs are met by what is supplied in a situation.

High-Maintenance Need Profile: A need profile characterized by greater needs for achievement and flexibility and a lower need for security.

Lifestyle Need Profile: A need profile characterized by greater needs for security and flexibility and a lower need for achievement.

Need Profile: The mix of needs that characterize an individual.

Empower Gender Diversity with Agile Software Development

INTRODUCTION

Gender issues have recently been discussed extensively with respect to the computing fields (Bair & McGrathe-Cohoon, 2005; Camp, 2002; Margolis & Fisher, 2002). One of the discussed issues is the "shrinking pipeline" phenomenon (Camp, 1997). Camp shows how, in addition to the shrinking of the pipeline upon transition from high school to graduate school, the pipeline has been shrinking also at the bachelor-degree level since 1983. She argues that since the number of women at the bachelor's level affects the number of women at levels higher in the pipeline and in the job market, this phenomenon is of great concern.

The shrinking pipeline is explained in various ways. Among other explanations, the image of the field as requiring long hours of programming is a dominant one. Here is an illustrative case. The April 3, 2003, edition of the *Pittsburgh Post-Gazette Business News* addressed the question of why more women are not involved in the tech fields.[1] This question was discussed by a panel, assembled by the Pittsburgh Technology Council a week before the article was published, which included some of the region's most successful women. Among other arguments, Robbin Steif, chief financial officer of Maya Design, said, "It might be an issue of self-selection—women might not be risk takers." Then she added, "It might also have something to do with the work/family issue, because entrepreneurs work way more than 40 hours per week."

This article focuses on software development teams using one of the agile software development methods. A high quality of working software is the primary measure of progress; however, agile software development processes, in addition, promote a sustainable pace for all the individuals (developers and users) involved in the software development process,[2] welcome requirement changes even in late stages of the development, and favor face-to-face communication. Based on our observations of agile software teams both in academia and in industry, we claim that such software development frameworks enable women to gain new and better positions in the hi-tech industry in general and in software development teams in particular. We view this article as an example of how diversity can be achieved in software teams. In our current research, we explore other dimensions by which diversity can be achieved in software teams, such as minorities and nationalities.

The perspective and data that are presented in this article are part of our research about human aspects of software engineering, specifically our comprehensive research about cognitive and organizational aspects of agile software development methods both in the industry and academia (Dubinsky & Hazzan, 2004; Dubinsky, Talby, Hazzan, & Keren, in press; Hazzan & Dubinsky, 2003a, 2003b; Tomayko & Hazzan, 2004).

BACKGROUND

The aforementioned image of the hi-tech industry in general and the software industry in particular was developed mainly during the dot-com bubble era. In those days, the media painted a picture of the dot-com world as a sleep-on-the-office-floor and sacrifice-your-family-time way of life. This image might tend to discourage women from entering the computing field and can partially explain the significant decrease in the female population of computer-science students over the past 20 years, from 35% in the 1980s to a 15 to 20% level at the beginning of the millennium (Camp, 1997; Davies & Camp, 2000).

The above picture accompanied data that indicated that the software industry suffers from many typical problems. For example, software projects fail to be delivered on time, exceed their budget, and do not comply with the requirements put forth by the customer (see, for example, Fairley & Willshire, 2003). Furthermore, according to the National Institute of Standards and Technology (NIST) news release[3] on June 28, 2002, "[s]oftware bugs, or errors, are so prevalent and so detrimental that they cost the U.S. economy an estimated $59.5 billion annually, or about 0.6 percent of the gross domestic product."

The Agile Approach and Extreme Programming

During the 1990s, the agile approach of software development started to emerge as a response to the problems of the software industry. Specifically, the agile software development approach, composed of seven methods, formalized development frameworks that aimed at overcoming these characteristic problems of software projects (Highsmith, 2002).

Extreme programming is accepted as the most commonly used agile software development method. It is based on four values expressed by 12 practices, which support and complement each other. The four extreme-programming values are communication, simplicity, feedback, and courage. The 12 practices, as originally envisioned by Kent Beck (2000), are the planning game, pair programming, refactoring, simple design, continuous integration, test-driven development, collective ownership, coding standards, short releases, metaphors, a sustainable pace, and on-site customers.[4]

The extreme-programming values and practices were selected based on the accumulative insight derived from extensive experience in the software industry, and from the recognition that quality software systems should, perhaps, be developed by adhering to very specific and detailed practices. Rather than stating principles and development phases that can be interpreted and implemented differently by different software teams, the extreme-programming practices outline a very detailed procedure for the actual development of software systems.

Since extreme programming is the most accepted agile software development method, when we assimilate it with a specific software development team, we adopt its values and practices as basic and, if necessary, adjust them in the spirit of the agile approach according to the team's needs. In this article, we refer to the adjusted extreme-programming method as the agile method.

Women's Management Style

According to Fisher (1999, p. 32), "Women's style of management is based on sharing power, on inclusion, consultation, consensus, and collaboration. Women work interactively and swap information more freely than men do. Women managers encourage their employees by listening to, supporting, and encouraging them."

In addition, recent research studies have identified several characteristics attributed to women's management style. Here are some examples (italics added by authors).

- *Women's management style is more equal and collaborative, often described as 'transformational', in contrast to the traditional 'transactional' style preferred by men who rely on power position and formal authority.* (Vinnicombe & Singh, 2002, p. 121)
- *Recent research indicates women's management style, which is centered on communication and building positive relationships, is well suited to the leadership paradigm of the 90's.*[5] (Peters, 2003)
- *The women's management style builds very much on participation by the employees and mutual trust, and they become very disappointed if the employees do not live up to that trust.* (Kjeldsen & Nielsen, 2000)

Needless to say, these attributes are compatible with any good management style; however, as the above quotes indicate, research attributes them to women.

E

Data Resources

The data presented in this article are gathered from two resources. The first is comprehensive research that takes place at the computer science department of Technion—Israel Institute of Technology in a project-based operating-systems course. In this course, the agile method has been used since the summer 2002 semester by teams of 10 to 12 students, each team guided by an academic coach. Each student is a developer and, in addition, has a management role that deals with a specific aspect of the software project management. In other words, all students are involved in specific managerial aspects in addition to their role as software developers (the description of all roles is presented in Dubinsky & Hazzan, 2004). A Web-based tool is used for project management and for students' personal reflections written after almost each weekly meeting. The data gathered in this course represent 27 projects developed through the agile method by about 300 students. We would like to highlight the fact that diversity in these teams was expressed not only in terms of gender. For example, one of these teams consisted of males and females, Arabs and Jews, religious and nonreligious students, and new immigrants and native Israelis. It is felt very clearly how this mix influenced negotiation, discussion, and cooperation in the work style. As has been mentioned before, we further explore this phenomenon.

The second resource for data is long-term research (started a year and a half ago) in the Israeli Air Force software unit. In this case, we guide a software team in the assimilation of the agile method and consult during its implementation process (Dubinsky et al., 2005). The data in this case represents one project with 15 teammates involved.

MAIN THRUST OF THE ARTICLE

The agile approach reflects the notion that development environments should support communication and information sharing, in addition to heavy testing, short releases, customer satisfaction, and a sustainable work pace for all individuals involved. The main characteristics of women's management style as quoted above are collaboration and sharing, communication, and trustful and positive working relationships. In what follows, the suitability of the agile approach to the characteristics of women's management style is presented and accompanied by data gathered from the above resources. Specifically, we examine the above-mentioned characteristics of women's management style in light of the agile principles that support them. Based on this analysis, it is argued that the agile method has the potential to be very well suited to women's management style.

Communication

Communication is vital for an agile team in order to be effective and to produce quality working software. A communicative-oriented examination of the behavior of 294 students, who worked according to the agile method during eight semesters in 27 different groups, reveals that females are equally communicative. Specifically, the communicative behavior is measured using the electronic forum that the students use. Figure 1 illustrates this observation, presenting the percentages of the number of students—228 males (77.6%) and 66 females (22.4%)—and the percentages of the number of forum messages the students sent—4,702 messages by males (77.2%) and 1,391 by females (22.8%).

This observation of female students who are equally communicative reoccurs each semester. Figure 2 presents the two most not-equal semesters: In Figure 2a, the female students were less communicative, but in Figure 2b, the female students were more communicative than the male students. These two figures illustrate that even in

Figure 1. Communicative behavior

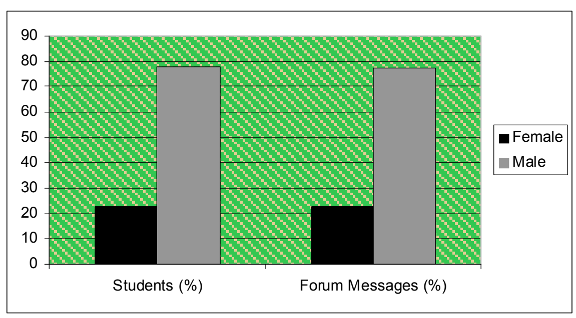

Figure 2. Communicative behavior in two specific semesters

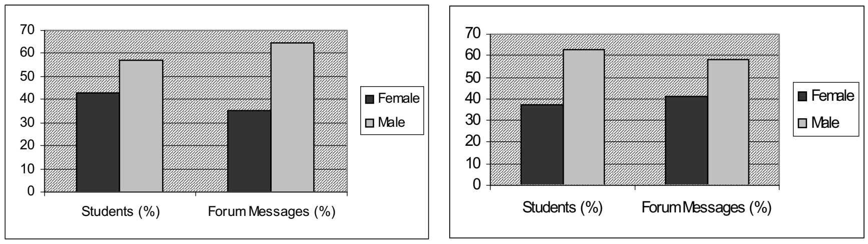

these not-equal cases, the difference is expressed in a small percentage. Specifically, in the semester represented by Figure 2a, the percentage of female students was 42.9% and the percentage of their forum messages was 35.4%; in the semester represented by Figure 2b, the percentage of female students was 37.5% and the percentage of their forum messages was 41.5%. Due to space limitations, we are unable to present examples of messages and their analysis. However, based on a preliminary analysis of such messages, as well as based on the data presented in this section, we may conclude that female students feel comfortable with the agile principle of communication.

Collaboration and Sharing

Collaboration and sharing in agile software development environments are expressed by some of the agile principles and practices. Developing things together, specifically through pair programming, is already found as one of the practices that can expand the shrinking pipeline (Werner, Brian, McDowell, Bullock, & Fernald, 2005).

We illustrate the fitness of this aspect of the agile method to female students by data taken from one semester. In this semester, three groups of students—altogether 32 students including 20 males and 12 females—were guided by three different academic coaches and developed three different products. Specifically, we examine one answer to one of the last week's reflection questions, which asked whether the work in a large team of students contributed to the software development process, and if yes, how.

Out of 20 males, only 11 answer the question, using altogether 469 words (average 42.6, median 36). Out of 12 females, 9 answer the question, using altogether 965 words (average 107.2, median 110). We present the word-count data since it delivers a clear message: The female students found the question intriguing.

An in-depth examination reveals additional aspects. Looking for phrases that indicate collaboration, we found that 8 males out of 11 and 7 females out of 9 used collaboration phrases. Here are several examples of collaborative phrases: "it was a great challenge to coordinate all teammates ... ", "The experience…involves interpersonal relationship ...", "I think that everyone felt during the semester that he has a backup in any case of a problem." Looking for phrases that indicate sharing, 1 male out of 11 and 3 females out of 9 use phrases that indicate sharing. Interestingly, all the sharing phrases referred to situations in which other teammates shared information and ideas with the student who answered. For example, one student answered, "In this way you can learn more about other people's ideas and solutions." As we can see, female students feel comfortable with the agile principles of collaboration and sharing.

One of the solutions to the implementation of the agile method in the industry addresses the inclusion of the software quality-assurance aspect into the general software teamwork, and by doing so ends the ongoing competition between developers and quality-assurance testers. In a previous work (Dubinsky et al., 2005), we present a set of agile metrics that emerged during the first release of a product. One of the metrics, Product, describes the size of the product by counting test points. The sharing event we would like to highlight here happened after three iterations when it became clear that test writing causes a bottleneck. Consequently, it was decided that at the beginning of the fourth iteration, the main tester would teach the developers to write automatic test scenarios for the code they develop. Accordingly, during the fourth iteration, the tester taught the developers to write tests, and consequently wrote fewer tests by herself. The result was a sharp increase in product size during the fourth iteration when more and more developers started writing tests. We bring this story here since the accumulative experience with software development processes teaches that such knowledge sharing is very rare and therefore should be appreciated.

Trust and Positive Working Relationships

These two features of women's management viewpoint are grouped together since both, as is explained in what follows, convey a less competitive working environment. As mentioned previously, the agile method lays out specific practices that aim at guiding software developers during the process of developing quality software products. In our opinion, this attribute—the laying out of specific procedures—enhances trust and contributes to positive working relationships. More specifically, if specific procedures are adhered to, and if it is clear that by following such procedures no one is being taken advantage of by others since everyone is following the same procedures, the tendency toward competition is reduced and the element of trust is intensified. Further examination of this perspective is presented in Hazzan and Dubinsky (2005).

So far, one can agree that it indeed seems that the agile method suits women's management frameworks very well. But, at the same time, one can claim that since the agile method is about software development, and since this industry requires a long workday, as previously explained, women would tend not to join agile teams even though it may be compatible with their values. However, as it turns out, and as will be explained in what follows, even this barrier has been eliminated in agile software development environments.

One of the agile principles is sustainable pace. The rationale for keeping sustainable pace is that overworked programmers are unable to produce quality code. Since other agile principles, for example, developing together, ensure productivity during the 40-hour week, agile programmers can work at a sustainable pace, be productive, and produce quality code. The following data illustrate this productivity. Based on 31 projects in which developers were early adopters of extreme-programming or agile methods, Reifer (2002) indicated a 25 to 50% reduction in time to market. This evidence shows that the agile method inspires a productive and efficient working environment without long work hours. The agile method delivers the message that quality and productivity can be achieved at a sustainable pace as long as the work hours are managed efficiently.

As it turns out, it is not only the agile method that advocates the sustainable-pace concept. For example, in *Software Project Management*, Hughes and Cotterell (2002) state,

There is good evidence that productivity and the quality of output goes down when more than about 40 hours a week are worked ... Clearly, it is sometimes necessary to put in extra effort to overcome some temporary obstacle or to deal with emergency, but if overtime working becomes a way of life then there will be longer term problems. (p. 226)

Indeed, in some cases this principle is presented as a general guideline or as a recommendation. At the same time, however, in agile development environments this concept is one of the core principles of the approach, and for an agile team, working at a sustainable pace is an integral part of the development framework.

FUTURE TRENDS

Encouraging potential female software developers to join the agile community requires an explanation of the development environment that this method inspires. This can be done in various educational frameworks. Indeed, following their origins in the industrial sector, agile methods have been explored in computer-science and software-engineering education, in educator symposiums instituted in conferences on agile methods (e.g., Eckstein, 2003), and in general computer-science and software-engineering education conferences (e.g., Bergin, Caristi, Dubinsky, Hazzan, & Williams, 2004).

CONCLUSION

Many associations undertake to promote women in the hi-tech industry. In most cases, these organizations seek ways to help women adjust to the prevalent work framework that characterizes this industry in general and software projects in particular. By presenting the agile software development environment, in which women can feel comfortable without requiring any adjustment, this article offers another way by which to recruit women into the software industry, and in doing so, helps to partially expand the shrinking pipeline.

ACKNOWLEDGMENT

We would like to thank the Samuel Neaman Institute for Advanced Studies in Science and Technology and the Technion Fund for the Promotion of Research for their generous support of this research.

KEY TERMS

Agile Software Development: The software development approach that values individuals and interactions over processes and tools, working software over comprehensive documentation, customer collaboration over contract negotiation, and responding to change over following a plan (http://agilemanifesto.org/). Several software development methods belong to this family; the main ones are extreme programming, the Crystal family, scrum, feature-driven development (FDD), DSDM (dynamic system development method), and adaptive software development.

Extreme Programming: Extreme programming is the most accepted agile software development method. According to the way it was originally described in Beck (2000), it is based on four values and 12 practices that together create a software development environment that encourages communication, simplicity, trust, and feedback. In the second edition of Beck's work (2005), it is rephrased in order to reflect the changes that occurred in the software industry.

Pair Programming: One of the extreme-programming practices. In pair programming, every piece of code is written by two teammates, where one acts as the driver and the other as the navigator; that is, one examines the details of a specific code and one examines the code from a more global point of view.

Software Development Method: A collection of principles and practices that inspire the development process of software products. During the relatively short history of software development, different software development methods have been suggested. Though there are differences between them, they all include the core activities of software development: requirements, design, coding, and testing.

Software Engineering: The application of engineering principles to software. It applies principles of computer science and mathematics for the development, operation, and maintenance of software. Software engineering addresses not only the technical aspects of building software systems, but also social, management, and cognitive topics.

Empowering Homemakers to Become E-Homepreneurs

Chong Sheau Ching
eHomemakers, Malaysia

INTRODUCTION

A number of factors explain why homemakers would want to transform themselves into home workers. Among these are the desire to rebuild confidence in one's own abilities by earning money after years of being a homemaker, the formation of a new network of mother friends who are also business partners, and the learning of skills needed for a home-based business (Ping, 2000). One of the skills that are increasingly being developed among groups engaged in business enterprises is the utilization of ICTs for work. For example, an ICT project in South India involves the setting up of telecenters that enable rural families to access ICT. The training of educated youth, especially women, in operating information shops has resulted in groups of women with small business enterprises and savings cooperatives (Balaji, Kumaran, & Rajasekarapandy, 2002). An important feature of the groups' use of ICTs for work is the strong sense of ownership that the communities develop for the telecenters, as well as the participation of women in the management and use of the telecenters. Close consultation between the project staff and users, gender sensitivity, and the use of local language in the computer programs are the important features of the project.

To specifically address the needs of disadvantaged women in Malaysia, the eHomemakers (http://www.ehomemakers.net) network started a pilot project in 2002 known as Salaam Wanita. The Salaam Wanita community consists of aspiring home workers and homepreneurs from the Klang Valley and Ipoh. Members are urban-based, low-income, and unemployed homemakers (single mothers, disabled persons, caregivers for disabled or aged dependents, and those who are chronically ill like SLE [systemic lupus erythematosus] patients who cannot work or go outside to work due to sensitivity to light and susceptibility to injuries). They are mostly homebound because of physical disabilities or home situations. Some are plagued by depression and suicidal tendencies. Consequently, they are economically constrained due to their inability to find work or business opportunities outside their homes. The Salaam Wanita project is designed to empower these women to network, and to gain ICT and microentrepreneurial skills for socioeconomic self-reliance.

JUSTIFICATION OF GENDER-GOVERNANCE FRAMEWORK

Information and Communications Technologies for Development (ICT4D) is increasingly recognized by the development community and governments as an effective means for poverty alleviation. Helping the poor and disadvantaged to become e-entrepreneurs requires organizational as well as governance and business-model innovation if the microenterprises are to be integrated into a market-based ecosystem for them ("Imagineering Rural Friendly Solution," 2005). Development goals can be attained if the information and skills transfer is based on a social-justice approach through the building of webs of exchange for the use of the marginalized (Gurumurthy, 2005).

The gender-governance framework[1] was propounded based on eHomemakers' experiences.

The key elements that form the basis of the framework are as follows.

Empowerment Must Reflect Women's Own Voice

ICT is proven to empower poor women, rural farmers, and slum dwellers in selected cases from Africa to Asia (Gerster & Zimmermann, 2004; Masud & Paim, 1999). These recent analyses show that successful ICT4D should be people centered, acknowledging the reality of people's lives with appropriate responses.

Tan (2000) cautions that the information age empowers the individual to become the epicenter of the world, affecting changes with impacts on the psyche as well as the physical body. Racing the engine of change indiscriminately will undermine the well-being of those least able to adapt and affect their ability to act rationally on their own.

Field Belenky, McVicker Clinchy, Rule Goldberger, and Mattuck Tarule (1986) propound that sanctioning women's voices in development allows each individual to be understood on her own terms, helping her to be responsible when her conception of self is rooted in a sense of connection and relatedness to others. Women's roles and maternal practices shape women's thinking about human development. The authors group women's perspectives of knowing into five categories: silence (women experience themselves as voiceless), received knowledge (women conceive of themselves as capable of receiving and producing knowledge), subjective knowledge (truth and knowledge are conceived as private matters), procedural knowledge (women learn and apply objective procedures to obtain and communicate knowledge), and constructed knowledge (women view all knowledge as contextual and experience themselves as knowledge creators). As such, women's development is about helping women to develop authentic voices, emphasizing connection, understanding, and acceptance of women's realities.

An increase in disadvantaged women's ability to go from silence to the other four perspectives of knowing will enable them to enter and sustain viable e-entrepreneurship. Such transformation must be carried out in a lifelong learning manner to promote the knowledge gained.

The Need for Women's Space

Inclusive women's movements and organizations should be for all women who are part of them. However, a mechanism is needed for integration and meaningful participation (Alpizar & Wilson, 2005). The centrality of indigenous gender knowledge production, and the communication and sharing of information among women stakeholders are essential for gender transformation with the use of ICTs (Radloff, 2001).

In addition, as disadvantages of ICT4D sometimes outweigh the benefits, the issue of gender exclusivity gives rise to the need for safe and secure electronic spaces for women. Such spaces will lead to women-led and women-defined development models (Wood, 2000).

Control and Ownership

As affirmed by Barch and Leon (2000), redressing unequal power relationships needs different empowerment levels: conscientisation (the disempowered become convinced of the need for actions), recognition as legitimate interlocutors (who determines what issues should be the bases of actions, and who get to be the players), and the building of power to negotiate issues of concern. If these empowerment levels are to be applied to disadvantaged women within the context of e-entrepreneurship development, it means that having the know-how to use ICT creatively and strategically (find, manage, produce, disseminate, decide, and intervene proactively at the individual level) is more important than access to ICT after conscientisation occurs. An ICT-development framework, for disadvantaged women and by disadvantaged women, instills leadership growth and sustainability momentum because the control and ownership belong to women.

Such a framework can also transform the benefactor-beneficiary relationship into a principal-client one with ICT as the catalyst.

Governance as Accountability

If the poor and marginalized are to gain basic assistance, they need to gain ownership of both the process and the outcomes (Rakodi, 2002). For development organizations to achieve true human security, they need to redress gender inequity and be accountable to women's rights (Rao, 2003). A motivated group under a development framework with strong governance principles (for self and others) brings positive changes to the group members.

Indicators and Barriers for Women's Informatization

To evaluate the level of women's informatization, the development of relevant indicators, mainly for monitoring and evaluation, can also measure the informatization rate and characteristics. They act as basic resources for change. Such indicators have not been defined in the Asia-Pacific region (Kio, Yong, So, & Hyun, 2001).

Strategic gender interest requires women to develop, create, and implement content and services that best answer their needs and interests (Jensen, 2005). Unfortunately, women, especially those in the south, face many negative experiences in the adoption of ICTs (Banks, 2000). Surveys by two women's electronic networks, APC and WINAP, revealed that women's organizations and information activists faced limitations in using ICTs. Emphasizing access to solve digital-divide problems does not address power imbalance and marginalization (Scott, Singh, & Wanasundera, 2001).

ICT is neither gender neutral nor gender blind. It discriminates against women, especially the disadvantaged, who stay at home. The way ICT operates does not support the social-economic development of disadvantaged women fully because of the barriers faced by them. ICT4D efforts for gender empowerment should make the overcoming of barriers a priority action goal within the gender-governance context.

In conclusion, a gender-governance framework with the above five elements enables women to overcome disadvantaged situations to network, and gain strength and knowledge as interlocutors. It makes women responsible for their actions and eventually influences others to be responsible for their conduct to the women.

GENDER-GOVERNANCE FRAMEWORK

Gender governance is both a goal and a process, which seeks to create a platform on which women take ownership of the management of networks and information sharing. eHomemakers attempts to promote demand-driven gender governance through information sharing, networking, and activities that enable and empower women to work from home. By combining the essence of working from home, the vigour to empower women, ICT opportunities, and the leveraging of experiences and knowledge shared within the community, disadvantaged women can achieve economic self-reliance and gender empowerment.

The 5A Process of Change outlines how women can take part in the creation of governance structures and mechanisms for their specific needs and interests. The processes are as follows:

- Awareness of the problem
- Acceptance of the need for change
- Action to be taken
- Assimilation maintaining the change
- Assessment of progress

A disadvantaged woman needs to break through barriers in order to acquire opportunities that lie ahead. Each stage of the change reflects different levels of economic empowerment. The process of empowerment is therefore a sequence of women's actions by which a gender issue, economic empowerment, can be tackled.

The first three stages require women home workers to realize and accept that they can change their situation by undertaking certain actions toward change. For e-entrepreneurship building, the assimilation stage is the beginning of the process of change, when a woman is able to use ICT to do business by networking and managing information resources on her own to ensure business viability. When she reaches the assessment stage, she completes the process of change to reach gender governance as she is able to evaluate her own efforts to overcome the barriers and take action to overcome them without heavy costs (monetary and nonmonetary) to herself. She is then able to grow her business with ICT usage and becomes an active member in business and cyber support networks. Her feedback, input, and responsive actions to the networks' needs form part of the governance of the information networks she belongs to. Because the networks' members own, control, and manage the information resources, they are able to spur corporate governance and e-governance.

RESEARCH

A 1-year research project to identify the barriers these women faced in the entry of entrepreneurship and e-entrepreneurship was conducted in 2003 and 2004 under the Pan Asia 2003 Networking Small Grant. The gender-governance framework was further refined for advocacy. One hundred and seventy-five women Salaam Wanita members participated in computer training, motivational talks, networking meetings, two questionnaire surveys, and focus-group discussions. The findings from the surveys and discussions were analyzed, and a list of major barriers to ICT and entrepreneurship were identified. Based on these, a list of indicators on women's empowerment progress was developed. The gender-governance framework was also tested during the research period.

FINDINGS

Some Salaam Wanita members within the study group have successfully overcome their disadvantages by taking control of their destinies. The effectiveness of the 5A Process of Change as a framework for assisting homemakers is evident among the successful home workers. They became aware of their problems and accepted the need to change. One of the major actions they have taken to control their disadvantaged situation is to learn new skills such as basket weaving, typing, translation, and computer and hand-phone skills. Through the project, they learn to network, to use the knowledge to market their products and services, and to be more proactive in turning their lives around.

The major barriers identified are the presented in the following sections.

General

Attitude

The single major barrier preventing Salaam Wanita members from taking up access to knowledge is the low-key attitude that takes the form of low self-confidence, high risk aversion, and passivity. They are afraid of venturing out on their own and are quick to quit when faced with obstacles.

Finances

Financial constraint is an obstacle in the acquisition of ICT equipment, maintenance, and operation even when the home-business options identified require little or no capital at all. It is also a problem if the time for home chores is adversely affected, resulting in additional costs to the disadvantaged women. They single out the cost of acquiring equipment as the main obstacle to the setting up of income-generating workstations at home.

Circumstances

Those who are chronically ill, disabled, or taking care of disabled or elderly dependents are unable to effectively enter the action stage of the process of change. This barrier is also related to their gender roles and work burden at home. Homebound women with disadvantaged dependants have less family and social support, resulting in heavier workloads at home and less time for any self-improvement activities.

Barriers to Using ICT

- **Intrinsic Nature of ICT Hardware and Software:** ICTs are not user friendly for the disabled and SLE patients. Reading text, looking at a glaring screen, and having to sit and use the hands prevent effective usage.
- **Ignorance and Fear:** The majority of women lack self-confidence and are often unable to learn basic skills even after several training sessions.
- The lack of immediate financial returns prevents them from regularly attending training sessions.

Barriers to Entrepreneurship

- Finances
- Lack of knowledge of basic business principles and the use of ICT as business tools
- Insufficient time for uninterrupted work
- Minimum family support to enable them to venture out of the house
- Discrimination by companies
- Transportation problems

- Lack self-knowledge
- Risk aversion and self-confidence
- Lack of networking
- Time
- Location

The indicators for tracking the progress of disadvantaged women in similar conditions were identified. As indicators of access, opportunity, and participation, they are related to the personal abilities of women in knowledge and skill enhancement, self-confidence building, and dealing with the external environment.[2] Another indicator area is related to the external environment (i.e., the organizational, environmental, technical, and governmental). The indicators measure a continuous process of change that is essential when establishing a network of thriving e-homepreneurs. Each of the indicators determines how and why changes in women's lives can happen within the gender-governance context. The indicators developed identify problem areas and give rise to recommended measures to resolve the barriers identified.

The indicators are divided into the following categories: the general (family and social networks, personal attributes and issues, home circumstances), the external, and technology.

CONCLUSION

Recommendations that resulted from the study are as follows.

- Change of attitude through viable role models
- Leadership cultivation for the formation of work clusters
- Innovative learning and training to address special learning needs
- Increased awareness through media
- Creation of specific policies for home working, gender mainstreaming into the national development, and relevant and specific assistance programs
- Research and development activities on innovative ICT tools and integrated platforms, content delivery, and access

Disadvantaged women are in a helpless and powerless position. They are especially vulnerable to the fast-changing pace of ICT revolution whereby technologies become obsolete within a short time span, and rules and governance are evolving constantly. Yet, ICTs are also opening immense possibilities to women. While the introduction of ICTs may make women work at lower skill levels, others who learned a combination of ICT and entrepreneurial skills experienced skills upgrading and new work opportunities (Saloma, 2001).

It is therefore imperative to ensure that women have access to ICTs at a level on which they can use them for work in accordance to their realities. In the case of the urban disadvantaged women, ICT4D for poverty alleviation should thus include gender governance: the ability by women to own and control the management of information networks for themselves and by themselves as the basis for gender mainstreaming. The framework should be used as an evaluation tool for projects involving e-entrepreneurship, e-networking, teletrading, and ICT-based self-help. The indicators developed from this study measure a continuous process of change that is essential when establishing a network of thriving e-homepreneurs. Each indicator determines how and why it leads to changes in women's lives within the gender-governance context.

KEY TERMS

Digital Divide: The term digital divide describes the fact that the world can be divided into people who do and people who do not have access to—and the capability to use—modern information technology, such as the telephone, television, or the Internet. The digital divide exists between those in cities and those in rural areas. The digital divide also exists between the educated and the uneducated, between economic classes, and, globally, between the more and less industrially developed nations.

E-Homepreneur: An entrepreneur who creates and manages a home-based business using ICTs.

Gender Mainstreaming: Mainstreaming a gender perspective is the process of assessing the implications for women and men of any planned action, including legislation, policies, or programs, in any area and at all levels. It is a strategy for making the concerns and experiences of women as well as of men an integral part of the design, implementation, monitoring, and evaluation of policies and programs in all political, economic, and societal spheres so that women and men benefit equally, and inequality is not perpetuated. The ultimate goal of mainstreaming is to achieve gender equality.

Governance: Issues related to the involvement of stakeholders—scientists, the industry, consumers, and public authorities—in the process of innovation-policy design, implementation, and evaluation.

Homepreneur: An entrepreneur who creates and manages a home-based business.

Home Workers: People who either telework or run home-based businesses.

ICT (Information and Communications Technology or Technologies): An umbrella term that includes any communication device or application, encompassing radio, television, cellular phones, computer and network hardware and software, satellite systems, and so on, as well as the various services and applications associated with them, such as videoconferencing and distance learning.

ICT4D (Information and Communications Technologies for Development): An initiative aimed at bridging the digital divide (the disparity between geographic locations or demographic groups who have and do not have access to or the capability to use technology) and aiding economic development by ensuring equitable access to up-to-date communications technologies.

SLE (Systemic Lupus Erythematosus): Commonly called lupus, it is a chronic autoimmune disorder affecting virtually any organ of the body. With lupus, the body's immune system, which normally functions to protect against foreign invaders, becomes hyperactive, forming antibodies that attack normal tissues and organs, including the skin, joints, kidneys, brain, heart, lungs, and blood.

ENDNOTES

1 The proposed gender-governance framework was developed by Chong Sheau Ching, manager of eHomemakers, in 2002.

2 The emphasis on welfare, awareness, access, opportunity, and participation is also at the heart of the gender-equality and women-empowerment framework (United Nations Children's Fund, 1994). The gender-governance framework's contribution to this kind of analysis lies in its attempt to introduce the use of ICTs for the attainment of gender equality and women's empowerment.

Engendering Universal Access to ICT in Rural Areas

Sonia N. Jorge
Consultant in Communications Policy and Regulation, Gender and Development, USA

INTRODUCTION

The concept of community access to information and communication technologies (ICT) has gained widespread attention as a strategically vital response to the perpetual lack of affordable access to ICT and ICT services in the developing world, particularly in rural and peri-urban[1] poor areas. Community access is not in itself a new idea; however, it provides an encouraging policy approach to overcoming the wide disparities of access and, as such, to provide opportunities for developing societies and historically disadvantaged regions and populations to participate in the newly emerging social and economic orders. This article focuses on community access centers as essential to facilitate access to ICT for women in rural areas in the developing world.

TOWARDS UNIVERSAL ACCESS: THE NEW POLICY DIRECTION

Universal service is traditionally defined as access to a telephone in every household. While the percentage of households with telephone service is high in developed countries, it is quite low in most developing countries. According to the International Telecommunications Union (ITU), by 2003, 96% of households in high income or developed countries have a telephone. In contrast, only about 13% and 37% of the households in Africa and Asia, respectively, had a telephone. In terms of teledensity, high-income developed countries had about 71 lines per 100 inhabitants, while countries in Africa and Asia had on average 5.5 and 14 lines per 100 inhabitants by 2003 (ITU, 2003). When we look at the urban-rural disparity in developing countries, the figures are even more depressing. While about 60% of the population in developing countries live in rural areas, more than 80% of the telephone lines are in urban areas. Women are a large percentage of rural populations and women-headed households are increasing everywhere.

The magnitude of this problem—*the access gap* (or the digital divide)—has led to a recent rethinking of universal service policies for developing countries. Indeed, a telephone line per household may not be economically or technically feasible for many developing countries. Therefore, the wider concept of *universal access* to ICT has become the focus. This new approach to universal service provides a shift from the concept of a "telephone per household" to wider "community access" to telecommunications and related services. In fact, it not only broadens the definition but also changes the concept of access to telecommunications to mean access to ICTs. ICTs include, in addition to traditional telephony, faxing services, computer services, photocopying, electronic mail, Internet access and access to an array of local, regional and national information previously available only to a few.

Community access centers, or telecenters, have recently become a development option to address the lack of access to ICT in many countries of the world, particularly developing countries. They offer an alternative model for access in areas traditionally lacking telecommunications infrastructure, such as rural and peri-urban areas, and provide an array of ICT services, training and resources needed for communities' development.

Despite their potential, community access centers will most likely function and be successful within a specific policy environment, one that develops and promotes the necessary support systems and appropriate policies to allow for sustainable centers (e.g., ensure gender equity in the implementation process, promote pricing policy that favors discounts for community access centers' services, financial incentives that promote investment where it is most needed, among others). If policy makers want to contribute to universal access in their countries, experience around the world shows that they should focus their attention on the demands of their rural and peri-urban population, and community access centers provide an option worth investing in.

COMMUNITY ACCESS CENTERS: A GENDER PERSPECTIVE

Despite greater awareness and evidence on the impact of gender analysis in development work, women and girls continue to benefit marginally from developments in ICT and access to services in many countries and environments. Women's ability to benefit from the access to and use of ICT as tools for social and economic empowerment is constrained in a number of ways, including social and cultural factors, income levels, education levels and illiteracy, and lack of knowledge on the potential of ICT, among others. According to a recent report, the following are some key socio-cultural factors that constrain women's use of ICT, particularly in rural areas (Gurumurthy, 2004, p. 24):

- *Cultural attitudes discriminate against women's access to technology and technology education.*
- *Women are less likely to own communication assets—radio, mobile phone.*
- *Women in poor households do not have the income to use public facilities.*
- *Information centers may be located in places that women are not comfortable visiting.*
- *Women's multiple roles and heavy domestic responsibilities limit their leisure time. Centers may not be open when it is convenient for women to visit them.*
- *It is more problematic for women to use facilities in the evenings and return home in the dark.*

Gender analysis and considerations are often neglected or integrated only too late (Hafkin & Jorge, 2002). Even in community access center projects, which tend to be community focused and supposedly more aware of community needs, gender has not become an integral part of the planning equation. A few centers around the world have committed themselves to targeting women and women's needs; however, they have encountered tremendous difficulties. Most of these problems

Figure 1.

Self Employed Women's Association (SEWA): Promoting ICT Use Among Women

SEWA, India, is a member-based organization of poor, informal-sector women workers. Two-thirds of its members live in rural areas and are home-based workers, vendors, manual laborers, service providers and producers. SEWA's ICT unit has been exploring the use of ICT as a tool to increase the efficiency of rural micro-level enterprise activities to secure poor women's livelihood. SEWA has successfully taken an integrated and holistic approach to the use of ICT for rural development, such as providing its members with access to information; training them with communication tools and customized software; technical training on repairing their tools; generating job opportunities; and also providing child care and health care. Some of their current activities on ICT include:

- Imparting basic computer training for semiliterate women before they are introduced to communication tools, such as Internet and customized software for their micro-enterprises
- Providing technical training, such as maintenance and repairs of their tools
- Providing loans for mobile phones for informal sector workers; that is, vegetable vendors
- Proving health advice and nutritional information by linking with hospitals via video conferencing for villagers who are laborers and service providers who do hard physical work to earn a living and survive; that is, construction workers and salt workers
- Exploring various partnerships with different medical institutes and organizations for providing better access to health care services for its members; that is, telemedicine.

Source: Dhara Patel, coordinator, ICT, Self Employed Women's Association (SEWA), India, presentation at the World Bank, July 2003, cited in Financing ICTD: A review of trends and an analysis of gaps and promising practices, the report of the Task Force on Financial Mechanisms for ICT for Development, UNDP (2004).

Figure 2.

Community Telecenters – Beyond Access

Beyond generating new jobs for women, ICT are being used in projects that address other gender and development issues related to poverty reduction. For instance, projects in South Asia that focused specifically on income-generating activities and direct employment benefits for women created a space for information exchange, provided support networks and developed a range of interrelated social, technical and economic skills. Participants acquired the confidence for autonomous activity that made a significant contribution to their empowerment. Although ICT have not yet had significant impact on creating employment and generating income for very poor and marginalized women, there is potential through increasing their engagement with ICT to expand social networks and introduce new modes of learning that can play a key role in overcoming poverty in the future.

Nabanna is a project located in Baduria, in West Bengal, India. Women in Baduria did not have structured local communication networks that promoted access to information or provided spaces for sharing information and knowledge. Many of the women involved in the project report that they have gained more respect in their local communities as a result of the ICT skills learned at the Baduria ICT center—both learning to use a computer and accessing and distributing information to local people. This has resulted in greater respect at both family and community levels. Younger women feel they are able to approach the job market with greater confidence. There has also been an emergence of solidarity—since women learn to use computers together at the ICT center, they also often discuss their problems, creating a sense of unity among them and also bringing forth inherent and latent leadership qualities.

Source: Ramilo, Jorge, & Hermawati (2005); http://www.bellanet.org/leap/docs/136121e.pdf?OutsideInServer=no

result from lack of gender analysis and training to correctly address the specific needs and demands of women and girls. A number of women organizations have had greater success in introducing ICT to rural women (see the box). It is, however, crucial to invest in gender analysis and training to ensure that access centers consider gender issues from the planning stages through implementation and evaluation.

By integrating gender analysis in their planning process, community access projects will be able to more clearly identify the disparate needs of women and men in the communities they serve. Specifically, they may consider all of the following requirements in the planning states:

- Conduct active outreach (i.e., to promote the center and ensure that it works with women's organizations active in providing services to the community)
- Ensure financial accessibility (i.e., price for access and for services)
- Ensure physical accessibility (i.e., strategic location)
- Provide training (e.g., training for women by women on various ICT-related areas)
- Ensure relevance (e.g., provide content relevant to local women's needs in their own language)
- Build confidence (e.g., promoting use by women and facilitating income-generating activities)
- Enable participation (e.g., creating welcoming environments).

Community access centers that take these factors into account are more likely to attract women users, increase demand for their services and, consequently, become sustainable enterprises. Community access centers can further benefit rural women and girls and contribute to their lives in numerous ways (see the box), including:

- Providing access to an array of ICT and related services, such telephony, access to computers and computer training courses, access to the Internet and e-commerce opportunities, access to radio programming and other audio-visual media, access to government information, employment information and opportunities, tele-education programs, health care information and, in some cases, actual treatment via tele-medicine programs
- Providing a business opportunity, in that many women or women's community organizations can become owners or managers of different types of community telecenters

- Creating jobs for women in telecenters, where women can participate in community development activities and better incorporate women's specific programs within telecenter plans
- Providing community-specific or community-focused programs, such as literacy projects, relevant content development opportunities, ICT training, farming or other economic activity information, trading information, government data, health information and projects, among others
- Providing women-specific or gender-aware programs, such as literacy projects, ICT training (for personal, community and business use), knowledge sharing programs, e-commerce initiatives and women's health information projects, among others
- Providing an incentive for businesses to locate in rural areas in the proximity of telecenters and to employ telecenter-trained workers
- Providing the skills necessary for members of rural communities to begin to develop their own business applications, such as developing community-based Internet service providers (ISPs), as has been the case in the United States.

UNDERSTANDING THE CHALLENGE AHEAD

Considering the possibilities, it is clear that community access projects must integrate gender in all stages of project development and implementation. Experiences from telecenters around the world show that, among other things:

- Women use the telephone (and increasingly, mobile phones) more then computers
- In general, women feel more intimidated by computers (particularly older women), but are interested in learning
- Lack of relevant information in local language is a disincentive for use of ICT services
- ICT provide opportunities beyond access, including networking and knowledge sharing among women
- Due to high illiteracy rates, many women relate best with radio, video, audio and other multimedia sources of information
- Women are more comfortable with women trainers and, in some cases, more comfortable in women-only training environments
- Most women would like to use resources provided by community access centers.

Clearly, women are interested in using ICTs; however, it is essential that community access centers being implemented throughout rural areas address women's concerns and provide an adequate environment for women's participation in and strategic use of ICT.

KEY TERMS

Community Access Centers or Telecenter: Generally refers to a community-owned and -operated initiative with the goal of providing affordable access to ICT and ICT-related services relevant to the specific community it serves (including locally relevant content in local language, a focus on the preferred technology, etc.).

Gender: Gender refers to culturally and socially constructed roles and behaviors of women and men, and identifies the social relations between women and men. It is distinct from the biological difference between women and men.

Gender Analysis: It involves the systematic research and analysis of information based on gender differences and relations, in order to address inequalities and work towards gender equality.

Information and Communication Technologies (ICT): New ICT generally refer to telecommunications technologies (i.e., telephone, fixed and mobile, fax, radio, TV, satellite), computer technology (i.e., to process data) and networking technologies (i.e., the Internet, voice-over internet platforms, etc.).

Universal Access to ICT: The ability of any individual, regardless of location (geographical location), income, gender, race, age, language and so forth to access ICT at a shared community access point at a reasonable distance (which can be defined by walking distance, number of meters, kilometers or miles) from his or her household. The concept of universal access also encompasses the notion of affordable access (i.e., a price that community members can pay).

ENDNOTE

1 Peri-urban areas are those areas in the periphery of major cities and where poor populations tend to settle when they migrate closer to urban centers. Peri-urban areas often include large shanty-towns or illegal settlements with little or no infrastructure and high rates of poverty.

INTRODUCTION AND BACKGROUND[1]

We describe an intervention that uses computer science (CS) faculty and students to create an inclusive learning environment. Our intervention model assumes that persistence and retention are the result of a match between student motivation and abilities and the university's social and academic characteristics. This match in turn influences the effective integration of students with the university and, as a result, their persistence and retention (Cabrera, Castaneda, Nora, & Hengstler, 1992; Tinto, 1993). We are currently implementing and evaluating this intervention at Old Dominion University, a research intensive urban university with a culturally diverse student body, and Norfolk State University, an urban and historically black university (HBCU) that primarily emphasizes teaching.

A MODEL FOR CREATING INCLUSIVE LEARNING ENVIRONMENTS

Organizational Support for Faculty and Students

This portion of our model depicts external resources available to support change in faculty and students (see Figure 1). Support for faculty includes peers, teaching assistants, and external consultants who provide assistance in areas targeted for change, for example, pair programming practices. Support for students includes academic resources such as tutoring, advising, and mentoring. Professional organizations, such as the Association for Women in Computing, may provide support to both faculty and students.

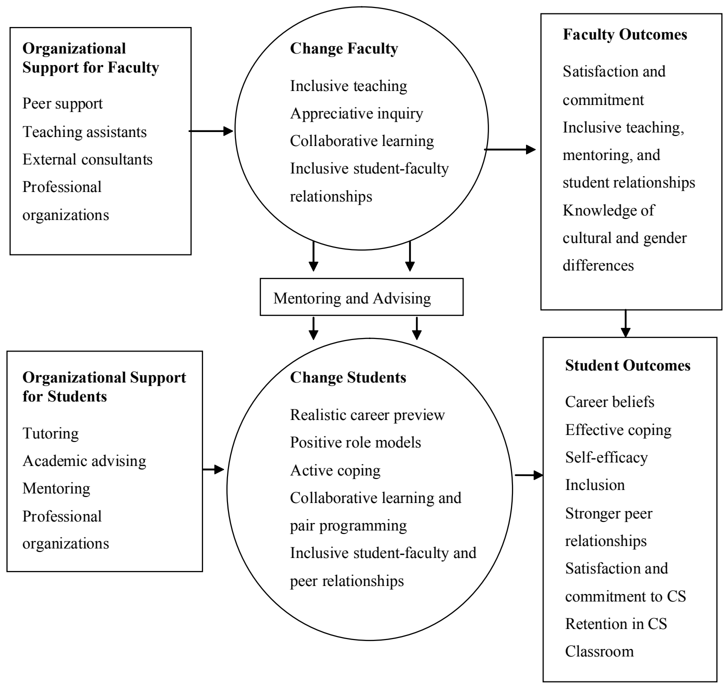
Changing Faculty

We focus on faculty because they influence student outcomes. The intervention concentrates on faculty who teach introductory programming classes because these classes represent the first and largest barrier to success in CS. We build on existing talents and strengths of faculty by emphasizing four skill areas: (1) inclusive teaching practices, (2) appreciative inquiry, (3) collaborative learning, and (4) inclusive student-faculty relationships.

Inclusive Teaching

Teaching style strongly influences retention in science, mathematics, and engineering (Seymour & Hewitt, 1997). Men and women and members of different ethnic groups experience IT work environ-

Figure 1. Intervention model for creating inclusive learning environments



ments and learning environments differently (Major, Davis, Sanchez-Hucles, & Mann, 2003; Steele, 1997; Steele & Aronson, 1995). Inclusive teaching encourages acceptance of diverse styles of learning and avoids actions based on stereotypes concerning group membership.

Appreciative Inquiry

Mentoring and tutoring typically focus on deficits and remediation. Appreciative inquiry, in contrast, emphasizes optimism, positive expectations, and challenge (Srivastva & Cooperrider, 1990). People tend to act in ways to fulfill expectations of powerful others, such as professors. Moreover, use of positive expectations energizes and directs behavior in a manner to fulfill expectations. Positive expectations may be especially powerful for those for whom low expectations are held (McNatt, 2000) or for those for whom gender or racial stereotypes influence expectations (Jussim & Eccles, 1992).

Collaborative Learning

Faculty members experience positive outcomes when they learn and share their experiences together. Collaboration may lead faculty to learn more deeply, encourage and support one another, explore new methods of teaching, increase colleagueship, discover and appreciate student differences, and develop a shared vision for teaching inclusiveness (Cox, 2002). Faculty who share learning experiences report increased interest in the teaching process, effectiveness as a teacher, and awareness and understanding of how differences may influence and enhance teaching and learning (Cox, 2002).

Inclusive Student-Faculty Relationships

The quality of exchange in relationships influences important outcomes. Inclusive student-faculty relationships enhance mentoring and advising and increase the retention of women and minority IT students (Cohoon, 2001, 2002; Gürer & Camp, 2002). Mentoring has more positive effects when it is not remedial in nature. Inclusive mentoring may be critically important because *not actively encouraging* women and minorities may have the same effect as *actively discouraging* them (Leggon, 2003).

Mentoring and Advising

Mentoring and advising link together faculty change and student change. Mentoring represents an attempt to provide information required for successful socialization and social support needed for effective stress management. Women and minorities may experience greater barriers to mentoring due to restricted access to mentors, unwillingness of mentors to mentor them, or disapproval by others of mentoring activities. Some women may also worry that a request for mentorship may be perceived to be a sexual advance (Ragins & Cotton, 1991). Women and minority students may have more difficulty establishing mentoring relationships because mentors often choose protégés with whom they can identify; this choice is often influenced by gender, race, and social class. Because women and minorities are under represented in CS, they may face greater challenges in seeking mentorship, particularly from mentors of the same gender or ethnicity (Wright & Wright, 1987). Fortunately, mixed-ethnic and mixed-gender mentorships can be as beneficial as same-ethnic and same-gender mentorships (Atkinson, Neville, & Casas, 1991).

It is important that mentoring and advising be inclusive and appreciative. Well-meaning support such as mentoring may elicit "stereotype threats" and lead to unintended negative consequences (Steele, 1997). Stereotype threat can be particularly insidious when combined with mentoring that emphasizes deficits and remediation. This may explain, in part, the positive relationship between mentoring and attrition in CS students reported by some researchers (Cohoon, Cohoon, & Turner, 2003).

Changing Students

Freshman and sophomore students in CS provide the second focus for change. Emphasis is placed on student attitudes, beliefs, and behaviors that are likely to improve socialization into the learning environment that exists in CS education and in the IT workplace. We have implemented a class required of new CS majors that has five components: (1) realistic career preview, (2) positive role models, (3) active coping, (4) collaborative learning and pair programming, and (5) developing inclusive relationships.

Realistic Career Preview

Our conception of a realistic career preview (RCP) is based on a practice developed in industry called the realistic job preview (RJP). The RJP provides potential new hires realistic—that is, both favorable and unfavorable—information that describes their likely work experience in the hiring organization. This method contrasts with traditional approaches to hiring and socialization that emphasize only favorable information. The logic of the RJP is that accurate information improves the fit between individual and organizational expectations and hence reduces later disappointment and dissatisfaction. Job candidates who receive RJPs have higher performance, job satisfaction, and organization commitment, and are less likely to quit (Philips, 1998; Premack & Wanous, 1985). RJP recipients are also more committed to training and profit more from it (Hicks & Klimoski, 1987). We expect to get the same results from the RCP.

The RCP presents to students a realistic portrayal of computer science education and careers. We use research findings to debunk common myths about working in IT, for example, we show that women in IT are frequently happy with their workplace and career in IT. We also "inoculate" students with previews of potentially difficult relationships and situations to prepare them for future challenges.

Positive Role Models

We use diverse IT professionals to serve as role models to show students the variety of career opportunities available to them with a degree in CS. Female students have less clearly defined career goals than their male counterparts when they begin studying science; they are disproportionately likely to abandon their plans to major in science after their first undergraduate year as a result (Seymour, 1999). Efforts to improve socialization during the first year of study, therefore, may have pivotal importance for improving retention among women. Margolis and Fisher (2002) recommend that early in their careers female students learn the context for technology and that they learn to understand why they are being asked to do what they do. This includes being presented with role models and career information that will help them to believe that they can be successful IT professionals.

Active Coping

Ethnic and gender minority status may interfere with the socialization process by reducing access to information and mentors and by increasing anxiety and stress (Jackson, Stone, & Alvarez, 1992). The extent to which newcomers to CS have a cultural or gender background that differs from most others in their department may reduce the rate of socialization and increase the likelihood of failure and quitting (Bauer, Morrison, & Callster, 1998). Women and minority students in CS report greater stress than other students (Davis, Gregerman, & Hathaway, 2003). The manner in which students deal with stress influences their level of social integration, institutional commitment, and intention to remain in university (Bray, Braxton, & Sullivan, 1999). We teach practices to cope with stress and anxiety that result from outsider status in order to strengthen academic and social integration. Enhanced academic and social integration increase commitment to academic goals and the academic institution and, as a result, enhance persistence and retention (Cabrera et al., 1992).

Active coping is the process of taking steps to remove or circumvent stressors or to reduce their impact (Carver, Scheier, & Weintraub, 1989). Active coping is positively associated with optimism, control, self-esteem, and hardiness, and negatively associated with anxiety (Carver et al., 1989). Moreover, when students experience stressful events, active coping is more likely to lead to efforts to: reduce stress, suppress competing activities, seek instrumental and emotional social support, and reduce maladaptive behaviors such as denial and behavioral and mental disengagement (Carver et al., 1989). Active coping also leads to increased information seeking, relationship building, positive cognitive framing of events, more successful socialization results and, as a result, increased satisfaction and intention to remain in the organization (Ashford & Black, 1996; Major & Kozlowski, 1997; Major, Kozlowski, Chao, & Gardner, 1995).

Collaborative Learning and Pair Programming

Pair programming provides an important means of collaborative learning for CS students (Williams & Kessler, 2003). Pair programming directs one partner to act as the "driver" who is responsible for writing code, while the "non-driver" partner is directed to continuously observe the work of the driver, watch for errors, and recommend alternatives. Programmers who cooperate with one another in this way work faster, detect more errors, create higher quality programs, express more satisfaction with their work, and report more confidence in their programs than do programmers working in isolation (Williams, 1999; Williams & Kessler, 2000a, 2000b; Williams & Kessler, 2001). Students who program together in pairs achieve higher grades and may be more likely to remain in CS (McDowell, Werner, Bullock, & Fernald, 2002; Williams, Wiebe, Yang, Ferzli, & Miller, 2002).

Inclusive Student: Faculty and Peer Relationships

As IT has permeated all organizational functions, employers of IT workers have encouraged development and use of "soft skills," such as communication, interpersonal relationships, teamwork, and working with diverse coworkers. Interviews with senior managers in IT reveal that such soft skills are better predictors of on-the-job success among IT workers than technical experience or skills (U.S. Department of Commerce, 2003), yet soft skills are not taught in conventional undergraduate CS programs (Bevan, Werner, & McDowell, 2002). Moreover, the global nature of IT requires the ability to work successfully with people from different cultural backgrounds; such knowledge should be part of the CS and IT curriculum (Little et al., 2000). Working effectively in teams and developing inclusive relationships with others from different cultures requires special knowledge and skills (Davis & Bryant, 2003). We highlight for CS students the importance of cultural differences and the need to consider these when developing relationships with faculty, graduate teaching assistants, and other students.

CONCLUSION AND FUTURE DIRECTIONS

With continued decline in enrollments, CS departments must pay attention to the learning environment if the percentage of women and minorities in CS is to increase. We describe a comprehensive, research-based intervention that is designed to enhance inclusiveness for all students—including women and minority students—by simultaneously addressing change in faculty and students and, as a consequence, increasing student commitment and retention.

Components of this intervention are likely to exert a synergistic impact on retention. Because there are multiple causes of women and minorities quitting IT study and careers, interventions intended to address these causes must be similarly complex. Moreover, interventions must be sufficiently flexible to allow their diffusion to educational institutions with different missions. The components of this intervention are broadly applicable and can be used to enhance inclusiveness and student retention in all areas of education.

KEY TERMS

Active Coping: Process of taking initiative to remove or circumvent stressors or to reduce their impact.

Appreciative Inquiry: An approach to change that emphasizes optimism and challenge rather than deficits.

Historically Black College or University (HBCU): About one-hundred private and public colleges and universities created to educate African Americans starting in 1837 with the founding of Cheney University (PA).

Inclusiveness: Work and learning practices that emphasize involving rather than excluding others. This includes acceptance of diverse styles of learning and avoids actions based upon stereotypes concerning group membership.

Pair Programming: A programming practice involving two programmers working together; one partner acts as the "driver" and is responsible for writing code, while the "non-driver" partner is instructed to observe the work of the driver and watch for errors, consider alternatives, and provide feedback.

Realistic Career Preview: An individual change and socialization practice in which one is provided a realistic preview of an occupational future that includes both positive and negative features.

Stereotype Threat: The extra pressure that members of underrepresented groups such as women and minorities may feel caused by fear of confirming and reinforcing negative stereotypes held about their group, for example, they are not skilled in mathematics and science. This extra pressure can reduce performance and persistence.

Environmental Context and Women in the IT Workforce

Eileen M. Trauth

INTRODUCTION

The rise of the network society involves a transformation of employment, in which power relations shift with the flow of capital, leading to downsizing, subcontracting and networking of labor. These processes facilitate flexibility and individualization of contractual arrangements in information work. As a whole, there is an increase in self-employment, temporary work, and part-time work, particularly for women (Castells, 1996). This transformation of employment brings heightened consideration about the characteristics of the labor force. Thus, one need is to examine environmental context and the possible connections between economic and cultural factors of a region and the experience of women in the IT workforce. This article summarizes an empirical study presented in greater detail in Trauth, Quesenberry, and Yeo (2005) that explored the influence of environmental context on women in the IT workforce by using the Individual Differences Theory of Gender and IT (Trauth, 2002; Trauth, Huang, Morgan, Quesenberry, & Yeo, 2006; Trauth, Quesenberry, & Morgan, 2004).

BACKGROUND

Previous research has shown that development of an information economy is highly dependent on environmental context factors (e.g., Benner, 2002; Castells, 1996; Kling & Turner, 1991; Trauth, 2000). Importantly, the development of these information economies has been shown to be the result of more than just technological infrastructure (Benner, 2002). The information economy in Ireland was the result of four groups of factors: infrastructure, public policy, economy, and culture (Trauth, 2000). Likewise, Kling and Turner (1991) argue that the development of an information economy is dependent on the number of information workers. Increased focus on information workers brings with it increased attention to gender representation in the IT workforce. Thus, it is critical to investigate the experiences of women in information work as their role has an increasing impact on the overall growth and stability of the network economy.

MAIN THRUST OF THE ARTICLE

This article reports on one aspect of a multi-year, multi-site, interpretive qualitative field study of women working in IT whose goal is to investigate the female under representation in IT. The guiding theory for this research is the Individual Differences Theory of Gender and IT proposed by Trauth (2002; Trauth et al., 2004, 2005, 2006) which examines the individual variations among women resulting from a combination of individual characteristics and environmental influences, in order to explain the under representation of women in the IT workforce.

Fifty-seven female IT practitioners were interviewed between October 2002 and October 2004. Eighteen of these interviews were conducted in Massachusetts, 25 were conducted in North Carolina and 14 were conducted in Pennsylvania. These women represent a wide range of ages, backgrounds, levels of management responsibility, and degrees of technical specialization. The racial make-up of the women includes Caucasians, African Americans, Asian Americans, Hispanics/Latinas and women from Middle Eastern descent. The interview data is also supplemented by participant observation data and by documentary data about gender and the IT sector in the regions involved in the study.

What emerged from the interviews are several themes about environmental context and women in the IT workforce. The following section discusses environmental context themes of economic and cultural factors from the three regions in the study: Boston, Massachusetts; Charlotte and the Research Triangle Park area of North Carolina; and central Pennsylvania. The cultural factors to be examined are: population migration patterns, ties to region, and attitudes towards women and women working.

Massachusetts Environmental Context

The Boston area is one of the wealthiest regions in the U.S. with a large and thriving IT economy. The information sector in this region grew steadily and boomed in 2001 with the employment of approximately 79,900 IT workers or approximately 4% of the overall labor force in the area. However, in 2003, the information sector showed a decline with the employment of approximately 64,100 IT workers or 3.4% of the overall labor force[1] (U.S. Department of Labor, 2004). In 2000, the national median value of owner-occupied housing units in the U.S. was $119,600 and 66.2% of the population owned a home. Also, in 1999 the national median household income[2] was $41,994 and the per capita money income[3] was $21,587. These figures are much higher in the Boston area. In 2000, the median value of owner-occupied housing units in the Boston area was $221,867 and approximately 55% of the city population owned a home. In addition, in 1999, the median household income was $54,536 and the per capita money income was $28,816. It is important to note that these figures are an average of three counties in the Boston area.[4] When examining statistics of affluent pockets of the Boston area, the figures are much higher (FedStats, 2005).

A noteworthy aspect of cultural context in Boston is the racial and ethnic diversity of its population. Much of Boston's population is comprised of racial and ethnic minorities including African Americans, Asian Americans, and Hispanic/Latino Americans in addition to Caucasian Americans (U.S. Census Bureau, 2000). The regional diversity is also represented in the interviews with women in this study. A number of participants noted the value placed on diversity and the open mindedness in the Boston region. As a result, many women felt it was easier to be a female IT worker in Boston than it would be in other geographical areas.

Several women also shared stories of how employers are proactive in creating a diverse IT workforce. These companies search for employees with a wide range of backgrounds, attitudes, and demographics in order to bring diverse people and mindsets to the workplace. Many participants also explained how employers value and devote significant amounts of corporate resources to diversity training. Furthermore, several women in the study felt that Boston is less hostile to women than other regions. However, even those women who said they did not personally experience hostility in the workplace did acknowledge that discrimination still exists. The women spoke about the difficulties associated with being a female in the IT workplace and succeeding in their careers. Many women shared stories of the challenges associated with moving into management positions and the need to rely upon characteristics—such as assertiveness—that are often socially defined as masculine.

Women constitute a large percentage of the labor force in the Boston region (U.S. Census Bureau, 2000, 2003). Many women in this study felt that being a female in Boston's IT workforce was not uncommon and therefore was not a central factor in workplace issues. Rather, these women felt that other demographic characteristics that they possessed, such as racial, ethnic and sexual orientation differences were more prevalent when workplace diversity issues arose.

North Carolina Environmental Context

North Carolina is undergoing a major transition from an economy based on agriculture and manufacturing to an economy based on IT and knowledge-intensive occupations. Two regions vital to this transition are Charlotte and the Research Triangle Park area. Charlotte is North Carolina's largest and most populated city. The information sector in North Carolina grew rapidly and boomed in 2001 with the employment of approximately 49,100 IT workers or approximately 3.6% of the overall labor force in the area. However, in 2003, the information sector showed a decline with the employment of approximately 46,300 IT workers or approximately 3.4% of the overall labor force in the area (U.S. Department of Labor, 2004). The median household income and the median value of owner-occupied housing units in Charlotte and the Research Triangle Park area is lower than the Boston region, but higher than the national average (FedStats, 2005).

Hanchett and Sumner (2003) explain that recruiting talent to North Carolina tends to be easy because of the area's reputation for an outstanding quality of life and a higher standard of living compared with other areas of the U.S. As a result, the population of Charlotte doubled between 1970 and 2000, making it the second fastest growing city in the U.S. with a population of 389,000. In addition, people from all over the country and around the world have relocated to Charlotte, bringing new ideas and customs with them. In Charlotte there are over 34,000 Asians (or 8.7% of the city population) and 60,000 Latinos (or 15.4% of the city population), which is an increase from 6,700 in 1990 (Hanchett & Sumner, 2003).

The move to an information age and the migration of people to North Carolina has occurred alongside the transition from what has been referred to as the "old south" to the "new south" (Hanchett, 1998). A majority of the participants spoke about this transformation in North Carolina. It appears in many ways that North Carolina is at a crossroads as the economic centers of the state transition from a traditional old south to a more progressive new south culture. Many regional norms, values, and attitudes appear to be in a state of flux as the area thrives economically and a new breed of North Carolinian populates the state.

The passing of the old south brings tension to the idea of a true southern belle and southern lady. A southern belle is described as a woman raised in "old-fashion southern values," and is typically associated with a family of social prominence and financial means. A southern belle is a woman with grace, manners, and strong family values. Participants in this study repeatedly discussed the concept of a southern belle and how that perception influences their lives and careers as women in the IT workforce in the South. Thus, there is a social expectation that southern women should be polite, well mannered, quiet when necessary, and place the highest importance on domestic roles even at the cost of a career outside of the home.

Most of the participants consider themselves to be "new south" women or southern Yankees and did not identify with the southern belle label. The majority of the participants reject the southern belle title because they place an importance on their career in the IT workforce and feel that the two concepts are in conflict. Several participants shared experiences of being treated as inferior or different from men in the IT workplace. Many women also felt that the regional culture contained an expectation that women act differently and more indirect in their workplace behavior. As a result, these women often felt it was a challenge to be assertive or to advance to higher levels of management.

In addition, several women in this study did not identify with the southern belle label because of geographical origin or race. Gina is originally from rural North Carolina, and explained that women from the mountain areas of the state are much different from southern belles. She felt that women from the mountain areas are much more independent and have a strong role outside of the home. Likewise, African-American participants in this study did not identify with the label of southern belles because of the radically different history of African Americans in the south.

Pennsylvania Environmental Context

The landscape of central Pennsylvania is often identified as the middle of the state excluding Pittsburgh and Philadelphia. Central Pennsylvania extends from the Southern Alleghenies along the Allegheny plateau and includes the cities of Altoona, Bloomsburg, Harrisburg, Johnstown, State College, and Reading. The information sector in central Pennsylvania has increased much slower than other areas in the U.S. with an employment peak in 2001 at approximately 46,700 IT workers or approximately 2.5% of the overall labor force in the area. In 2003, the information sector showed a decline with the employment of approximately 40,400 IT workers or approximately 2.3% of the overall labor force in the area (U.S. Department of Labor, 2004). The median household income and the median value of owner-occupied housing units in central Pennsylvania is much lower than that of Boston and Charlotte/Research Triangle Park (FedStats, 2005).

The women in this study explained that central Pennsylvania has a recent and growing demand for IT workers, but there is a shortage of skilled workers to fill these demands. As a result, many women felt it is easier to find IT work than some other kinds of jobs, so long as they have the necessary skills. Several women explicitly mentioned that their gender did not matter on the IT hiring market—it was technical skills that came first.

Yet, despite the lack of gender barriers to career entry, the women in this study shared stories of the difficulties they face as females in the central Pennsylvania IT workforce once they are hired. Many women felt they are continuously challenged and isolated in the workplace because of their gender. In order to compensate for these feelings, some women attempt to modify their behaviors to become more assertive.

Several participants also elaborated on how female participation in the IT workforce creates tension with regional cultural attitudes towards women working. The women in the study continuously referenced a regional cultural expectation for women to work and raise a family without filling a job intended for a male primary income earner. A few women shared stories of being passed-over for promotions or raises despite their exceptional work performance. Rather, the promotions and raises were given to male coworkers because they were considered to be the primary income earners for their families.

The aging population is a serious problem facing central Pennsylvania. Pennsylvania ranks second in the nation with residents over the age of 65 and ranks number one in the loss of young people aged 25 to 34 (Brookings Institute, 2003). In contrast to Massachusetts and North Carolina, the intransient nature of central Pennsylvania's population appears to create an environmental context in which newcomers feel like outsiders. Participants in the study who are not originally from central Pennsylvania felt like outsiders despite living in the region for several years. These women were attracted to central Pennsylvania because their skill sets were in demand, but continue to experience difficulties adjusting to regional norms, and building social and professional networks.

FUTURE TRENDS

This article contributes to discourse about the under representation of women in the IT workforce, in order to inform future research as well as diversity enhancement initiatives in the educational and employment arenas. Yet, an important caveat to this discussion of environmental influences is that these results are only an initial finding based upon data from three different geographical regions of the U.S. Future research will involve an additional round of interviews in each region along with continued collection and analysis of environmental context data.

CONCLUSION

These findings bolster an argument in favor of looking beyond the data at hand, to the women *in context.* As this article indicates, context might refer to state, province or region. Other work by Trauth shows that context can also be national context (Trauth, 1995, 2000; Trauth, Nielsen, & von Hellens, 2003). The argument for considering women's experiences in context challenges a prevailing tendency to generalize from one dataset to all women, everywhere.

KEY TERMS

Individual Differences Theory of Gender and IT: A social theory developed by Trauth (Trauth, 2002; Trauth et al., 2004) that focuses on within-group rather than between-group differences to explain differences in male and female relationships with information technology and IT careers. This theory posits that the under representation of women in IT can best be explained by considering individual characteristics and individual influences that result in individual and varied responses to generalized environmental influences on women.

Information Economy: Also referred to as the *information sector*, this portion of a nation's economy encompasses the work and workers engaged in the processing of information and the production of information tools. The information economy is divided into two sectors. The *primary information sector* is responsible for producing information processing and communication hardware and software, and information systems and services. It also includes the development of content for these systems. The *secondary information sector* consists of those organizations which process information in the course of accomplishing some other mission (Trauth, 2000, p. 5).

Interpretive Research: Research directed at understanding the deeper structure of a phenomenon within its cultural context by exploring the subjective and intersubjective meanings that people create as they interact with the world around them (Orlikowski & Baroudi, 1991, p. 5).

Qualitative Research: A term used to describe forms of social inquiry that aim at understanding the meaning of human action and that rely primarily on qualitative data (e.g., data in the form of words), including ethnography, case study research, naturalistic inquiry, ethno-methodology, life-history methodology, and narrative inquiry (Schwandt, 2001, p. 213).

ENDNOTES

[1] These figures are based on the Boston Metropolitan Statistical Area (MSA) of Essex, Middlesex, Norfolk, Plymouth and Suffork counties.

[2] Median household income is the average income of all household members over the age of 15 (Fedstats, 2005).

[3] Per capita money income is the mean income of an individual for a geographic region. It is determined by dividing the total income of all people over the age of 15 by the total population of the area (Fedstats, 2005).

[4] These figures are based on an average of Middlesex, Norfolk, and Suffork counties.

Factors Influencing Girls' Choice of Information Technology Careers

Monica Adya
Marquette University, USA

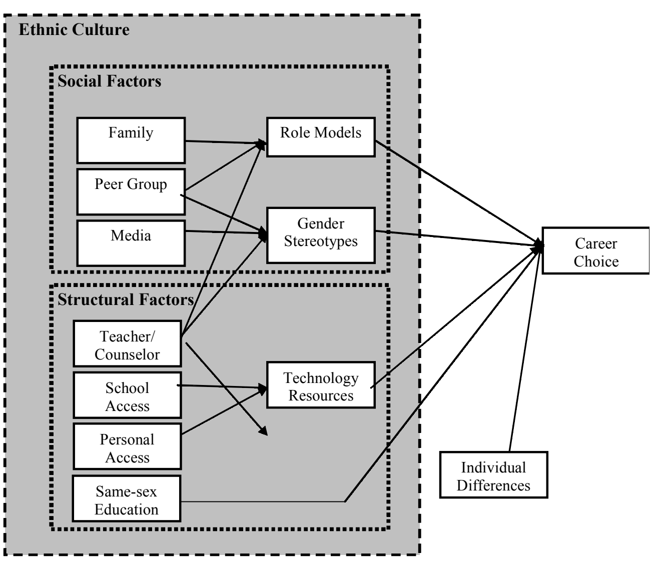
Kate M. Kaiser
Marquette University, USA

INTRODUCTION

Many western nations have experienced declining numbers of women in the information technology (IT) workforce (Trauth, Nielsen, & von Hellens, 2003). Between 1996 and 2002, women in the U.S. IT workforce declined from 41% to 34.9% (ITAA, 2003). This can hamper diversity and reduce the talent pool that can address needs of diverse end-users (Florida & Gates, 2002). Why do women choose IT careers or reject them? Multidisciplinary research on career genderization reveals gender imbalance (Trauth, Nielsen, & von Hellens, 2003). Career decisions against math, science, and technology (MST) are often made as early as age 11 without understanding long-term implications (AAUW, 2000). We examine influences on girls' choice of IT careers, modeling social, structural, and personal variables that affect IT career choice.

Using Ahuja's (2002) classification of social and structural influences on women's IT careers, Beise, Myers, VanBrackle, and Chevli-Saroq's (2003) model of women's career decisions, and individual differences suggested by Trauth (2002), we extend literature to children and adolescents' career choices. Social influences bias internal and external gender perceptions and stereotyping, role models, peers, media, and family. Institutional support such as teachers and counselors, access to technology, and same-sex versus coeducational schools are structural influences. While both can influence career decisions, social factors have the most influence on children's early perceptions. Both factors can introduce gender-stereotyping effects on career choices.

Figure 1. Factors influencing girls' career choices



Gender stereotyping explains how girls perceive their role in society based on subtle societal cues. It can limit opportunities for both sexes. We also examine personality traits and external influences that make children unique. Their individual differences draw them to activities and content areas such as problem solving and interaction with people. Finally, ethnic culture can exert an influence on social and structural variables. Figure 1 from Adya and Kaiser (2005) presents our career choice model that is discussed in the next section.

MAIN THRUST OF THE ARTICLE

SOCIAL INFLUENCES

Role Models

Career choices are influenced by role models who are often familial or educational rather than famous societal figures (Dryler, 1998). Direct forms of parental influence, such as the degree to which students see their parents choosing IT careers or having contact with technology, are strong motivators to train for technical jobs. Family members can also motivate career choices indirectly by encouraging girls to pursue careers perceived to be "masculine."

Women entering male-dominated fields come from families where mothers have four year degrees, mothers are working, both parents are highly educated, and success is considered critical (Jackson, Gardner, & Sullivan, 1993; Smith, 2000). Women choosing nontraditional careers recall fathers having a strong influence on career choices in nontraditional environments such as math, science, and technology (MST) (Gates, 2002; Trauth, 2002). Older brothers can influence girls toward "masculine" careers (Banks et al., 1992). Girls with only sisters chose careers that are more "feminine." Similar sibling influence is found for boys with male siblings.

Teenage peers have greater impact on social behaviors rather than career choices. During adolescence peer influence, particularly of boys on girls, impacts female self-concept, self-efficacy, classroom experiences, and external goal orientation. Such changes cause a clear demarcation between boys' and girls' career choices despite that girls score well on national level testing (Leslie, McClure, & Oaxaca, 1998). Among women, male peers play an important part in choice of MST as a career (Smith, 2000). Brekke (1997) on the other hand, attributes lack of participation in college-level physics to result partially from peer pressure that steers students away from MST.

Media

Media enhances gender stereotypes that emphasize physical image. Although girls interpret such images as unrealistic, they conform due to social pressure (Milkie, 1999). The few women shown in computer magazines, textbooks, and software are usually represented stereotypically (Na, 2001). Media does not depict women in positions of power or as active computer users. Analysis of television advertising reports males with central, authoritative roles having more credibility than women regarding product knowledge. Women are shown against the backdrop of children (Na, 2001). Trade journals and media may have changed for young adult women showing them in professional roles but young teens do not read these. Seventeen and Cosmo Girl, the two most popular teen magazines, have little content that portrays women in technology careers.

Gender Stereotypes

Girls' perceptions of IT jobs may mirror stereotypes that do not represent the dynamic and rewarding nature of the field (von Hellens, Pringle, Nielsen, & Greenhill, 2000). The Rhode Island Economic Policy Council (2000) reported that teenagers considered IT "uncool, nerdy, or boring." Steele (1997) found that gender stereotypes against female computer use negatively affected self-concept and career choices. Math has been stereotyped as masculine and is a critical filter that deters women from MST careers (Beise, Myers, VanBrackle, & Chevli-Saroq, 2003).

Beliefs about role-appropriate behavior restrict choice of careers in college. Up to age ten, girls have similar subject interests as boys and are perceived to be better at all or most subjects than boys. As career choices form, girls begin narrowing their career options, often excluding MST (Miller & Budd, 1999). These decisions are lifetime decisions that reduce opportunities to pursue technology careers.

What causes gender-biased perceptions of technology careers? Parental, teacher, and peer role models can carry hidden messages about boys' and girls' capability with computers (Volman & van Eck, 2001). Children whose parents have higher levels of education resist gender stereotyping while those whose parents have high school or less conform to gender stereotypes (Bouchard & St-Amant, 2000). Parents with stereotypical math perceptions impact girls' self-perceptions about their math ability and success.

STRUCTURAL FACTORS

Structural factors represent institutional support available to women to pursue careers. The role of teachers and counselors in exposing students to technology, access to computer technology both at home as well as in schools, and the nature of the school environment can influence genderization or neutralization of IT careers.

Teacher/Counselor Influences

Research uncovers negative influences of teachers and counselors on MST career choices reflecting a gender bias in directing girls towards traditional careers (Gates, 2002; Turner, Brent, & Pecora, 2002). However, women who moved from non-IT to IT careers indicated male professors as a strong influence (Canes & Rosen, 1995). Teachers stereotype roles by giving the impression that boys are inherently better with computers than girls. Teachers, both male and female, attribute certain expertise to boys and give them priority for computer use (Volman & van Eck, 2001).

Counselors devote little time on occupational and job counseling, ranking it fifth out of eight functions they typically perform (NCES, 2003). Since only 29% of girls receive support from career counselors, the amount of counseling is minimal. Moreover, middle and high school teachers and counselors are more comfortable advising toward traditional fields possibly because they lack IT background (Freeman & Aspray, 1999).

School Technology

Women IT professionals cite school access to computers as a prominent reason for interest in IT (Turner, Brent, & Pecora, 2002). School computer access has increased significantly but reports on gender differences in its use have been mixed. Durndell & Thomson (1997) report that differences in use of computers at school are non-existent or declining. Huber & Schofield (1998) observe more frequent and diverse use of computers by boys than girls.

Only 60% of teachers reported using computers for instruction, 41% assigned computer tasks, while 23% felt prepared to use computers and the Internet (NCES, 2000). Teachers who felt technologically prepared were more likely to use technology in class and assign materials requiring computers for problem solving and data analysis. The current generation of teachers, while knowledgeable about computer use for personal productivity, may have limited knowledge about IT career choices.

Home Technology

Boys use home computers more frequently than girls and are more likely to own computers or be prominent users of shared computers (Harris, 1999). They use computers more than girls as a social activity (Durndell & Thomson, 1997). Boys demand more power and functionality from home computers (Habib & Cronford, 2002). Students with home computers have significantly more positive attitudes towards IT in college (Selwyn, 1998).

Perceived usefulness and attitudes about computers are key determinants of IT usage intention and behaviors (Venkatesh & Davis, 2000). While increased technology access familiarizes children with computers, nature of use may influence beliefs and attitudes about technological careers. Although gender gap in technology access is non-existent, use of computers and the Internet is not. Boys use the Internet for a wider range of activities such as games, shopping, and finding information while girls restrict Internet use largely for e-mail and access to educational resources (NCES, 2002). Women exposed to play and collaboration-based assignments in training are more likely to choose MST careers (Smith, 2000).

Same-Sex vs. Co-Educational Schools

Sex-segregated environments inadvertently reinforce gender stereotypes, squander opportunities to address gender inequity, and expose students to teasing from peers in co-educational classes (Viadero, 2001). School environment has no impact on senior students from public schools with regard to math (Vezeau, Bouffard, & Chouinard, 2000). Students attending same-sex high schools have minimal pressures from the opposite sex and have a better sense of belonging (Brutsaert & Van Houtte, 2002; Watson, Quatman, & Eder, 2002). If high school experiences reinforce notions that boys adapt better to technical areas, same-sex students have no comparisons (Jackson, 2002). One might expect that students of same-sex schools would not embrace gender-specific career choices. Although structural factors may exert similar influences in same-sex and co-educational schools, peers may impact differently.

INDIVIDUAL DIFFERENCES

An emerging theory that challenges the essentialist (Venkatesh & Morris, 2000) and social construction (Adam, 2002) perspectives of gender and IT suggests that individual differences play an important role in forming career choices (Trauth, Quesenberry, & Morgan, 2004). It suggests that the socio-cultural environment of women shapes their individual responses and experiences as IT professionals. Many individual differences are split along gender lines (Trusty, Robinson, Plata, & Ng, 2000). Personality traits, enjoyment of computers, and overall outlook are some characteristics accounting for these differences. Women in IT reported several personality characteristics that made them different—powerful, forthright, strong, ambitious, driven, mathematical, logical, and less social than other girls (Trauth, 2002). Although female students enjoy using computers less than male students and perceive more problems with software, IT career women report higher levels of enjoyment with computers (Turner, Brent, & Pecora, 2002). Such factors may impact occupational choices at young ages.

ETHNIC CULTURE

The under-representation of women in the IT workforce is global but appears more severe in developed nations (Trauth, Nielsen, & von Hellens 2003). These studies find that women from India and China have more positive attitudes towards MST careers. Although both India and China represent similar economic environments, they represent a broad population that excels in MST careers. While market demands shape workforce trends, ethnic culture may provide more positive MST career orientations to women in these countries (Trauth, 2002). The lack of research suggests that cross-cultural examination of structural and social factors requires further investigation.

FUTURE TRENDS

Three decades of research may not reflect how IT pervades homes and schools today. Home computer use is equally divided between male and female users (NCES, 2002). Technology is being increasingly integrated in school curriculum and education and the popularity of Internet gaming and instant messaging can reduce a gender-based digital divide (Gorriz & Medina, 2000). Increasing number of women in the overall workforce and the knowledge that technical education is critical to success are other social trends that can promote the need for technology education.

Offshore software development in some countries emphasizes IT more than before. The U.S. is projected to face a shortage of 2 million IT professionals by 2006 but not enough students are graduating to fill this gap (O'Hara, 2000). India's emphasis on quality and its strong educational system has encouraged unprecedented software growth (West & Bogumil, 2001). Such market changes make IT a very attractive career, which in turn can affect families' work habits, education, and interactions. Will these trends make IT a more attractive field to the next generation?

CONCLUSION

Declining numbers of women enrolled in IT curricula and the workforce should motivate IT educators and policymakers to improve programs conducive to technology careers. Before teachers can provide gender-neutral counseling, they themselves need training in technology and its career options. Teachers and counselors can benefit from increased interaction with industry and universities as well as ongoing technological training.

Parental involvement clearly has a positive bearing on choice of IT as a career. As fathers continue to influence girls' career choices and mothers get involved in the workforce, educating parents about IT career options is important. The misperception of what IT professionals do and what skills they need to succeed can deter many college students from choosing IT. Improved marketing may alter these misperceptions. The technological outlook today is changing for the better. If we can successfully identify and manage student IT career perceptions during adolescence, women may increasingly populate the IT workforce and college level programs.

KEY TERMS

AAUW (American Association of University Women): Organization promoting equity for women and girls' education, and societal change. (http://www.aauw.org/)

Digital Divide: Demarcation between those who have access to technology and those who do not.

Ethnic Culture: Of or relating to large groups of people classed according to common racial, national, tribal, religious, linguistic, or cultural origin or background (Webster).

Gender Stereotyping: Making assumptions about one gender; generalizing or attributing characteristics to all people of that group.

Individual Differences: Unique characteristics applied to a person.

ITAA (Information Technology Association of America): Trade association of IT firms. (http://www.itaa.org/)

NCES (National Center for Education Statistics): U.S. government organization for collecting and analyzing data about education. (http://nces.ed.gov/)

Role Model: A person whose behavior in a particular role is imitated by others.

Factors that Influence Women and Men to Enroll in IT Majors

Claire R. McInerney
Rutgers, The State University of New Jersey, USA

INTRODUCTION

Because of the ubiquitous nature of information technology, there is a continuous need for IT professionals. There has been a steady growth in the information technology industry as well as an increase in the use of information technology. However, the number of qualified technology workers has not kept up with the demand for technology-skilled labor. One reason for the workforce shortage is that women are underrepresented. Not only are there many fewer women in the IT workforce, but there are fewer women entering and graduating from traditional technology-related academic programs like computer science (CS), computer engineering (CE), and systems science. In 1986, approximately 36% of the U.S. graduates in CS and CE were women; in 2004, 17% were women (Bryant & Irwin, 2001; Carver, 1999; Zweben, 2005). Of those earning doctoral degrees in 2004 only 18% were women (Zweben, 2005). Given that 51% of the total population is women, these statistics give a vivid explanation of why there is a shortage of IT workers.

BACKGROUND

In the United States in 1999, four core IT occupations—computer scientists, computer engineers, systems analysts, and programmers—employed over 2.2 million people (United Engineering Foundation, 1999). In 2004, only 0.3% of incoming freshman college women and 2.8% of men expressed an interest in majoring in computer science, according to the Higher Education Research Institute (n.d.). The numbers of students interested in engineering are also down despite U.S. Commerce Department reports that show 70.2 % of all vacant positions in science and engineering between 2002 and 2012 (a total of 1.6 million jobs) will be in information technology. All programmers and others who work in IT professions do not have university degrees; however, education remains a critical factor in preparing the IT workforce. In 2002, the number of students pursuing doctorates in computer science in the top 50 U.S. research universities fell to the lowest number in 12 years (Foster, 2005).

The small (and declining) numbers of women enrolling in IT-related degree programs in universities should be a cause of concern (Kossuth & Leger-Hornby, 2004). Parents of daughters might be concerned because high-paying IT jobs are not available to young women without academic credentials. Industry managers could be concerned that the underused potential of women professionals limits needed skills in the IT workplace such as organizational expertise, an understanding of customer service, and the ability to work collaboratively. With inadequate preparation for the IT field, women can miss out on opportunities for creative work, the chance to influence the IT field, and professional work that can be financially rewarding.

With limited numbers of women in positions in which software is being created, the female perspective in software products will be underrepresented. The consequence is that girls and young women may be less interested in the field of technology because the software, games, technology products, and so forth do not appeal to them.

FACTORS THAT INFLUENCE ENROLLMENT IN IT MAJORS

Career Interest

Although it is fairly common today to have more than one career in a lifetime, the choice of a university discipline and the subsequent career is one of the most important decisions that one will ever make. Men and women choose careers based on several cognitive and affective factors including the following:

- Deeply held values
- Self-knowledge
- Knowledge of careers (Niles & Harris-Bowlsbey, 2002). There are also societal factors that influence career choice. As Margolis and Fisher note (2002), women often express an interest in a balanced lifestyle that may include having children and giving attention to home and family. When they see computer science and other technology-related careers as requiring a singular focus on sitting at a computer and programming all day and far into the night, the cost is too great for them.

An academic major is often related to the career a student will pursue after graduation. In a study intended to learn what students and teachers viewed as effective recruitment techniques and the factors that influence students to enter technology education programs, students indicated that they decided on a major while in high school rather than waiting until entering the university (Gray & Daugherty, 2004). Students may change their minds once they are at the university level, but many make the decision before applying to and matriculating in a university.

IT Career Choice

What are the factors most likely to influence a student to choose to enroll in an IT-related major? There is a strong connection between the quality of science and mathematics teaching and success in these subjects in high school and a student's interest in majoring in science and/or engineering. In a six-nation study (Australia, Canada, China, England, Japan, and Portugal), Woolnough and Guo (1997) found that science and math teaching had to be supportive, at an appropriate level of difficulty, and intellectually stimulating in order for students to be influenced to study the subjects at the university level. Secondary students in the study were also influenced to major in science and/or engineering (considered a traditional IT-related field) when they were involved in science competitions, had science-related hobbies at home, and perceived science and IT-related professions as satisfying, bringing high status, and having good salaries.

Success in mathematics in primary and secondary school is often seen as an influential factor in becoming interested in computer science and other information technology-related subjects. Computers by their very nature are computational, and the study of computing in precollege programs has often resided in mathematics departments. In a study that examined students' perceived ability in mathematics, researchers found that gender, years of high school mathematics, math self-efficacy, and math anxiety predicted choice of a science- or math-related college major (Hackett, 1985).

A Brazilian study of high school students found five underlying factors related to students' choices of an undergraduate major. The five factors that were found to be significant after interviewing over 1,000 senior high school students included liking the activity, family members' influence, previous experience in the field, access to information about the field, and the state of the job market. The researchers found that males mentioned family influence most often, and female students mentioned liking the activity related to their intended college major most often (Alchieri & Charczuk, 2003). In Ireland, McQuillan and Bradley (1999) conducted a study of 91 19-year-old first-year female university students to learn about women's underrepresentation in computing majors and careers. They found that women students were influenced to choose computing-related majors through career advice, university-based communications, the promise of excellent career prospects, the encouragement of family members, an interest in computer technology, and generic reasons such as the belief that computers are the way of the future. The results of this and other international studies outlining influences on selecting a major are summarized in Table 1.

In a study supported by the U.S. National Science Foundation, researchers at Rutgers University interviewed 41 men and women undergraduates enrolled in IT-related majors to determine the factors that influenced them in the choice of an IT major and career. The students from computer science, computer engineering, and information technology and informatics (ITI) listed the following as influential in their decision to study information technology.

F

Table 1. A summary of selected research studies on factors that influence students to choose a university major

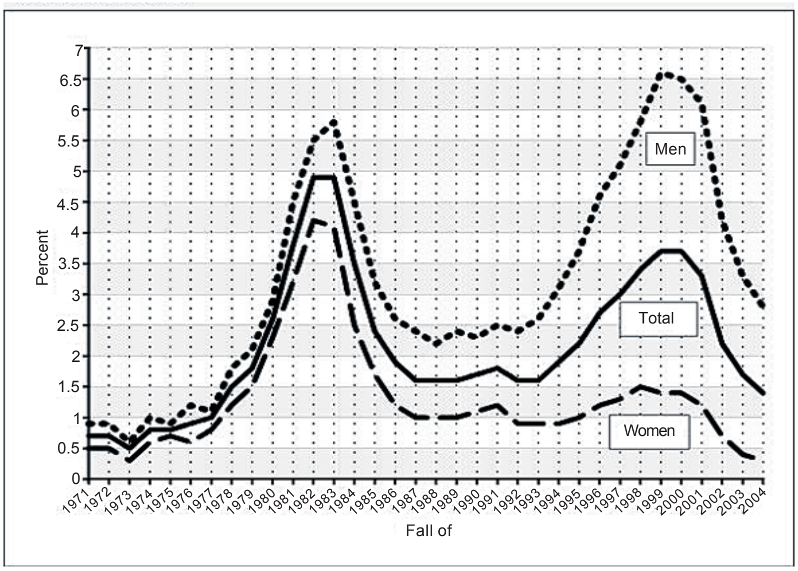
Country Context of Study	Authors	Education Level of Students	University Major	Factors that Influence Students to Choose a University Major
Australia Canada China England Japan Portugal	Woolnough & Guo (1997)	Secondary school	Science or engineering	- Involved in science competitions - Worked on science hobbies at home - Perceived science- and IT-related professions as satisfying - Viewed IT-related professions as having high status and good salaries
Brazil	Alchieri & Charczuk (2003)	Secondary school	Any university major	- Liked the activity - Was Influenced by family members - Had previous experience in the field - Had access to information about the field - Was aware of the state of the job market
Ireland	McQuillan & Bradley (1999)	First-year women university students	Computer science	- Read about computing in college prospectus - Heard about computing on college-information day - Was influenced by career advice from a teacher - Knew of good career prospects - Was encouraged by family members - Was interested in computing

- Were encouraged by family members and friends
- Liked mathematics
- Experienced success in mathematics
- Liked working with computers
- Experienced success in working with computers
- Liked the people-centered nature of the major (ITI students)
- Liked the multifaceted curriculum (ITI students)
- Completed an advanced placement (college level) computer course in secondary school
- Completed and enjoyed an IT-related course in secondary school
- Liked programming
- Liked working with hardware
- Liked the challenge of working with computers
- Anticipated good job opportunities
- Anticipated a good salary
- Anticipated a job with prestige
- Had a job in the IT field while enrolled in high school or college (McInerney, O'Donnell, DiDonato, & Giagnacova, in press)

Some students were employed in part-time paid positions in high school or college in which they worked with computers or computer applications, or solved computing problems, and success with this work influenced the student to enroll in an IT major. Students in the ITI major indicated that they liked the human factor emphasis and multidisciplinary nature of the major in which they were enrolled.

Although, as Foster reports (2005), the interest in traditional IT careers may be dwindling, there is still a fascination with technology that propels students to choose an IT-related undergraduate major. The numbers of students interested in a traditional CS major from 1990 through 2004 in U.S. universities are shown in Figure 1. The peaks and valleys of interest shown here seem to reflect social, cultural, and economic influences on choice of academic major. One can see that interest in computer science ballooned in the early 1980s when personal computers first became practical, affordable, and available for home and business desktop use. The next peak of interest (as indicated in Figure 1) came during what is commonly referred to as the dot-com

Figure 1. Percentage of probable freshman computer-science majors in U.S. universities (Source: Higher Education Research Institute; Vegso, 2005)



bubble in the late 1990s and early 2000s when there was a boom in the U.S. computer industry. As indicated, the numbers of women interested in enrolling in CS continue to be considerably lower than those of men. Even though common wisdom would dictate that the numbers of men and women enrolling in CS majors would even out over time, as they have in medical and law schools, that is not the case; the number of women in CS departments continues to decline.

IT Majors and Career Choices for Women

As statistics show through the trajectory of computer science majors in U.S. universities (Foster, 2005; Nelson, 2004; Vegso, 2005), the number of computer science majors is decreasing and the number of women majors in the field is dropping dramatically. Before career development interventions can be taken to encourage more women to consider IT, it is useful to examine the factors that encourage women to enter technology fields either while enrolled as students or as they enter the workforce.

Mentoring

Mentoring and modeling are strong influences on women who are seeking a career field (Catalyst, 2001). McQuillan and Bradley (1999) studied university women and technology in Ireland and found that role models provide powerful lessons and learning opportunities for female students. Unfortunately, though, there are limited numbers of women role models in the ranks of science and IT professors on university campuses. In the report on the status of women in computing science by a committee of the Association of Computing Machinery, one of the four primary challenges found for women who attempt to become computer scientists is the lack of mentoring and role models. As the report attests, "Mentors play a crucial, though usually informal, role in the training of young computer scientists" (Pearl, Pollack, Riskin, Thomas, Wolf, & Wu, 1990, p. 6). It is desirable for women to have female role models and mentors, the report continues, and any institution truly interested in encouraging women in technology must consider the provision of mentors and knowledgeable advisors in technology education and career counseling.

Work Experience as an Influence on Education and Career Choice

Another influence on choosing an academic field and ultimately a career is the opportunity to acquire hands-on work experience in a discipline. Research shows that the success of work-based learning depends on the structure of the experience. The cases in which work experience enhances students' education both academically and socially are those that develop practical skills and build confidence. In one study, internships at a university research lab succeeded in teaching lab techniques for DNA research while allowing students to apply chemistry and math knowledge learned in school (Stasz & Kaganoff, 1997). Internships and successive classes with the same teacher also help expose students to relationships with adults that nurture their self-confidence personally and within a field. One hypothesis related to choosing an IT career is that work experience in computer or other information technology laboratories on university campuses may influence students to choose to enter the IT workforce. According to Holland (1997) and Niles and Harris-Bowlsbey (2002), apprenticeships and internships can be important steps in the career decision-making processes.

Success in Secondary School and College

In their research with computer science majors in a top-ranked university computer science department, Margolis, Fisher, and Miller (2000) report that young women can develop a love for programming and IT through a successful experience in an advanced placement (college level) programming course in high school as well as through part-time computing-related employment. This love of programming often leads to a decision to major in computer science. Young women also discover a love of computing early on when they experience success in mathematics and science, and find that they enjoy solving puzzles, the art of logical and systematic thinking, and other intellectually challenging tasks. One gender difference researchers found is that women students often contextualize their interest in computing. Forty-four percent of the women studied saw computing as integrated with other experiences in human life and domains such as "medicine, space, and the arts," whereas only 9% of the men thought of computing this way (Margolis, Fisher, & Miller).

Self-Efficacy in Science and Mathematics

There is a strong connection between success and interest in science and mathematics and success in the study of computer science (Wilson, 2002). Wilson found that having a math background was the second most important factor in predicting success in academic computing. The most critical factor in computing success according to Wilson (and one supported by Margolis & Fisher, 2002; Pearl et al., 1990) is how comfortable students are in a computer science course. The comfort level is closely associated with self-efficacy. Women students can be confident and enthusiastic about enrolling in computer science majors, but when they encounter a hostile environment or one in which it seems that most of the other students have more experience with computing than they do, they often become unsure about their own abilities and quickly lose confidence and interest in IT.

Even though there has been an enduring relationship between self-efficacy in science and mathematics and an interest and aptitude in computing, the broad range of activities associated with information technology today can attract students with varied interests. Computer art and design, health monitoring and epidemiology informatics, technology-assisted learning, linguistic analysis, population tracking, and geographic information systems can all appeal to men and women with strengths in the humanities and social sciences.

FUTURE TRENDS

The number of information technology majors is declining, and the field continues to be one of the most inequitable among university majors. At the same time, the need for technology professionals continues. Outsourcing jobs, the uncertain economy, a "nerdy" image of the field (BBC News Online, 2001), the lack of mentors, a working environment that can seem unsafe (Pearl et al., 1990), and dual work-family issues (Machung, 1989; Pearl et al.,

1990) are all negative factors that present barriers for potential IT professionals. Margolis and Fisher (2002) acknowledge that change can happen, however. In 1995, 7% of the computer science freshmen at Carnegie Mellon University were women, but in 2000, the number of women rose to 42%.

Steps can be taken to improve the balance between men and women in IT including the following suggestions offered by the researchers at Carnegie Mellon.

- Admissions policies do not have to favor students highly experienced in IT if programs are available to allow inexperienced students to succeed.
- Attention needs to be paid to good teaching.
- Using introductory courses as "weed-out" experiences discourages students.
- IT curricula should contextualize the subject to apply to real-life situations.
- IT needs to move away from being viewed as promoting the hacker culture ideal; faculty can help by including students in their own research.
- Because so many students decide on their major in high school, universities need to reach out to faculty, staff, and students in secondary schools.

CONCLUSION

This discussion has reviewed the literature and research on influential factors in the choice of information technology-related university majors that lead to IT careers. Attention has been paid to women because they are underrepresented in information technology departments and professions. Although the situation is far from equitable, research continues on how university IT departments and IT workplaces might become hospitable and attractive to both men and women. It is beneficial to society and to the national interest to have a robust and educated IT workforce. Despite the trend toward downsizing and outsourcing, competent, creative, and innovative IT workers are the foundation of a solid information technology industry and an effective IT infrastructure for all.

KEY TERMS

Career Development Interventions: Steps that can be taken to help individuals develop an interest in a certain career. These actions can include counseling, apprenticeships, observing professionals in that career at work, and discussing the career with those experienced in the workplace.

Information Technology: As defined by Carver (1999), it is "the study, design, development, implementation, support, or management of computer-based information systems" and includes "all production and all applications of hardware and software."

Information Technology Careers: In the United States, they are generally considered to be computer scientists, computer engineers, systems analysts, and programmers. These are the professions in which individuals create new products, design systems, produce and customize software, and manage and implement technological innovations. Admittedly, there are many other kinds of jobs in which people use technology tools.

Information Technology Majors: They are generally considered majors in computer science, computer engineering, and information systems. These majors often focus on programming, product design, software development, and system analysis and design.

Mentors: Individuals who are usually teachers, family friends, or professionals who are influential in encouraging individuals in their academic study and career aspirations. Mentors are especially important for girls and women who are underrepresented in the academic departments and careers of mathematics, science, and technology.

Nontraditional Technology Majors: They are often developed as alternatives to traditional IT majors. Majors such as information technology and informatics, information management, and technology applications can include courses in programming, but they also include courses in human factors and people-centered subjects such as human information behavior, information policy, information retrieval, and social informatics.

Self-Efficacy: How one feels about one's abilities in a particular skill area. High self-efficacy refers to confidence and the perception of success. Low self-efficacy indicates a feeling of failure or lack of achievement or success.

A Faculty Role in Women's Participation in Computing

J. McGrath Cohoon
University of Virginia, USA

Holly Lord
University of Virginia, USA

INTRODUCTION

The success of efforts to attract and retain more women in computing is influenced by many factors that are beyond the control of academic departments. Industry downturns, public perception about job opportunities and the desirability of a computing career, and gender stereotypes about interests and abilities are only a few contextual features that are likely to be relevant but over which computer science programs have little or no control. Nevertheless, there are ways that departments can have a measurable influence over women's representation, and several of those ways depend on faculty.

Women's portion of undergraduate enrollment in computing majors is low on average, but it varies across institutions (Cohoon, 2006). Likewise, women's portion of attrition from computer science (CS) is a disproportionately high rate—32% annual attrition of women from the major. Comparing women's attrition rate to men's attrition rate in the same department shows that on average, undergraduate women switched out of the CS major at a rate six points higher than their male classmates. However, just as some departments enroll higher proportions of women, there are also some undergraduate computing departments that retain men and women at comparable rates. The first part of our discussion examines the faculty behaviors that distinguish undergraduate departments that retain women.

Women's portion of graduate enrollment in computer science and computer engineering (CSE) is also low, but similar to undergraduate programs, it varies by department—from 8% to 33%. The second part of our discussion examines the faculty behaviors that distinguish graduate departments that enroll women.

In this article, we take a department-level approach to identifying factors that are related to the gender-balance of post-secondary computing. We examine the considerable role that members of a department's faculty play in bringing about similar outcomes for men and women. First, we discuss faculty actions that can affect retention in undergraduate computer science programs, and secondly, we discuss faculty recruitment of women into graduate CSE programs.

BACKGROUND

Until recently, research on women's participation in post-secondary computer science was scant. As a result, much of the background literature for investigations on this topic consists of research on women's participation in science, technology, engineering, and mathematics (STEM). Overall, this body of literature shows strong evidence for the important role that faculty play in women's participation in STEM disciplines. For example, a comprehensive review of intervention programs designed to promote women and underrepresented minorities in STEM found positive outcomes when faculty play an active role in recruiting and supporting students (Building Engineering and Science Talent, 2004). Women in fields with high status rewards, such as computer science, are less likely to experience the supportive environments that they find satisfying (Hearn & Olzak, 1981). In addition to being dissatisfied, women who find the classroom climate in engineering to be unsupportive tend to have low class participation (Salter & Persaud, 2003). However, supportive interactions with individual faculty can compensate for an environment that might otherwise be unsatisfying (Hearn & Olzak, 1981). Further evidence identifies some specific supportive faculty behaviors and the benefits they offer women students.

Mentoring activities range from social and emotional support to instrumental support (e.g., showing students how to write grant proposals and get articles published, writing letters of recommendation, etc.). These activities increase students' academic self-confidence, academic success, and career commitment in STEM fields. For example, a survey of more than 300 graduate students at a single university (Ulku-Steiner, Kurtz-Costes, & Kinlaw, 2000) showed that when faculty provided students with both affective support (such as sensitivity to students' non-academic commitments) and instrumental support (such as finding financial aid), students' academic self-confidence and career commitment increased. The association between mentoring and these outcomes was strongest for women in disciplines where the majority of faculty members were men. This was the group of women who had the lowest level of self-confidence. The boost in confidence that mentoring provides could be one reason for the measurable improvement in academic performance and continued enrollment at an institution associated with mentoring. The mentored students in this university's three-year study earned 0.3 of a grade point average higher than non-mentored students who entered the study institution at the same time with the same sex, ethnicity, and high school GPA (Campbell & Campbell, 1997). The mentored students in this study were also less likely to drop out of their institution. The evidence from these studies demonstrates that mentoring students is one way that faculty members can improve student outcomes. Whether the outcomes benefit women in particular is not clear.

There is evidence that instrumental mentoring benefits women graduate students in STEM fields. A national study of chemistry, computer science, electrical engineering, and physics graduate students showed advisor support was related to female enrollment (Fox, 2001). Women's representation was higher in programs where women reported more advisor support than reported by women in other programs. This support included instrumental mentoring activities such as advisor help with "learning to design research, to write grant proposals, to coauthor publications, and to organize people" (Fox, 2001, p. 659). The women in departments where these mentoring-type interactions were more common also had higher expectations of graduating than women in departments where it was less common for faculty to provide such help. This association between graduate women's participation in STEM disciplines and instrumental mentoring by faculty demonstrates one way that faculty members can influence the gender composition of their programs.

Another way faculty members influence the gender balance of STEM programs is through role modeling. Role modeling is frequently confused with mentoring, but is actually a different function. In contrast to the more active mentoring, being a role model involves serving as an example of the attitudes and behaviors related to a role. Furthermore, role models do not need to personally interact with students to be effective. Their importance lies in the assumption that observing a person similar to oneself in a role increases one's ability to imagine oneself in a similar role. The paucity of women role models has often been cited as an important reason for the small number of women students in computing (Teague, 2002; Townsend, 1996).

Unlike mentors (Cohoon, Gonsoulin, & Layman, 2004), role models are most effective when they are socially similar to the observer. For example, course retention was higher for first-year women who were taught mathematics and science by female faculty (Robst, Keil, & Russo, 1998). This finding is particularly interesting because the impact of faculty gender was greatest in classes where there were few women students, as is often the case in CS. Similar results from a study of graduate students show that being the same sex as the observer is important but not sufficient for role models to be effective (Etzkowitz, Kemelgor, Neuschatz, & Uzzi, 1994). Interviews with faculty and graduate students in physics, chemistry, electrical engineering, and computer science at a single research university found that characteristics other than sex were important. In particular, women graduate students wanted to model themselves after women who balanced work with their personal lives. Thus, it appears that being female is not an adequate condition for effective role modeling, and that some behavioral attributes are required for female role models to improve the retention of women in STEM.

In addition to mentoring and role models, other types of supportive student-faculty interactions influence women's participation in post-secondary STEM disciplines. For example, a multi-institution study with in-depth interviews of undergraduates found that faculty support through a crisis of confidence can retain undergraduates in STEM majors (Seymour & Hewitt, 1997). When students experience a crisis of confidence, an incident that is particularly common among women (Beyer, Rynes, Perrault, Hay, & Haller, 2003), faculty intervention can prevent attrition from the major.

Thus far, we have discussed findings related to *retention* in STEM. Retention is an important part of student participation, but it can only go so far toward increasing women's representation. More women must be recruited if their representation is to approach parity, but there is little research that identifies successful methods for recruiting women at the undergraduate level. For example, role models do not appear to be an effective means for attracting more women to STEM fields. Panel data from three institutions produced no evidence that increasing the number of female faculty generally translated into more female majors (Canes & Rosen, 1995).

The rare case of effective recruiting is Carnegie Mellon University (CMU). CMU dramatically increased the proportion of women in their computing program through a set of interventions that included outreach to high schools (Margolis & Fisher, 2001). The CMU experience suggests that vigorous recruiting of women can increase the number of women enrolled. Deliberate recruiting, such as that done by CMU, is more common at the graduate level than at the undergraduate level, and it requires support from the administration as well as cooperation from faculty members.

Student progression to graduate school can result from recruitment, and it can result from action taken by undergraduate faculty. Undergraduate faculty members who encourage students and help them understand quality research promote student continuation to graduate programs in pharmacy (Gagnon & Cocolas, 1988; Henderson & Keeney, 1988). We will report on similar findings for students in computing.

In sum, the evidence from STEM disciplines indicates that faculty members can influence student outcomes and the gender composition of their programs. Active recruiting, role modeling, and support in the form of mentoring lead to women's satisfaction, class participation, academic confidence, better grades, career commitment, retention, and progression to graduate school. We will describe related findings for women's retention and progression to graduate school in computing in the next section.

MAIN THRUST OF THE ARTICLE

The main thrust of this article is that computing faculty can exercise measurable influence over women's participation in computing. This influence can be applied at the undergraduate level both to retaining women and advancing students to graduate study. Less is known about the graduate level, but it appears that faculty can influence the gender composition of their program through activities that recruit women.

Retaining Undergraduate Women in Computer Science

Recent evidence demonstrates that there are many ways computing faculty can promote women's retention. When they create an environment that compensates for our culture's lack of support for women in computing, faculty overcome the social forces that inhibit women's participation in postsecondary computing.

Two of our large-scale studies demonstrate the effect that faculty mentoring of undergraduates has on women's retention in computer science. A statewide study of 23 computer science departments in Virginia suggests that faculty mentoring can help alleviate the loss of women in undergraduate programs (Cohoon, 2001). This survey of faculty and analysis of attrition by gender found that departments retained women at comparable rates to men if faculty members mentored their undergraduate students. The subsequent nationwide study confirmed the value of mentoring and specified that faculty motivations for mentoring play an important part in gender-balanced retention (Cohoon et al., 2004). The value of mentoring for students in general will be discussed in the section on graduate programs. In this section, we discuss the effect that mentoring and other faculty behaviors have on retention.

The relationship between mentoring and gender-balanced retention depends on faculty motivations for mentoring particular students. Our nationwide study showed that when mentoring is motivated by a desire for diversity, undergraduate women were retained at similar rates to their male classmates. Unfortunately, fewer than 30% of responding faculty members were even slightly motivated to mentor by the desire for diversity. Their most common reason for mentoring was "superior student ability" (Cohoon et al., 2004). This focus on exceptionally able students was less common among women faculty members, who were more likely than men to mentor women undergraduates in order to promote equal representation. Regardless of a mentor's sex, the results of diversity-motivated mentoring were the same for male and female mentors—female retention in computing was closer to male retention.

These studies also show other ways that faculty actions influence women's retention in undergraduate CSE. In particular, encouraging students and emphasizing homework and academics over extra-curricular activities were associated with gender-balanced retention. For example, when faculty members simply encouraged their students to persist in a CS major, there was a measurable positive effect on undergraduate women's retention. Unfortunately, as with mentoring for diversity, fewer than half the faculty in the average department reported that they encouraged persistence (Cohoon, 2006).

The observation about the value of encouragement from faculty helps illustrate how seemingly minor elements of faculty-student communication can produce measurable differences in outcomes. Simply encouraging students to persist can promote women's retention, but defensive communication behaviors promote women's lower confidence and attrition from computing (Garvin-Doxas & Barker, 2004). According to this research, when faculty members create a supportive communication climate in their courses, CS is more inclusive of women.

Homework is another way that faculty members can have a positive influence on women's retention. Departments where faculty members expected nine hours of homework per week for one course were more likely to retain women at high rates than departments where less homework time was expected (Cohoon, 2006). This instructor emphasis on practice as a route to mastery of the subject matter helps women persist at rates similar to their male classmates.

Belief that successful students limit their extra-curricular involvement is a faculty attitude associated with gender-balanced enrollments. Faculty understanding of the effort required to master the subject matter helps female students succeed. As one faculty member put it in an interview following up on a study of undergraduate computing, "Everyone can get this stuff, but some have to devote more time" (Cohoon, 2006). Similarly, according to Margolis and Fisher (2001), the view that computing is a skill that can be learned if students apply themselves is common to women who persist in undergraduate CS. When their instructors endorse the same view, women are retained at rates approaching their male classmates' retention rates.

Finally, the pedagogical approach employed by faculty can work to retain more women in computing. When faculty members create a collaborative learning environment in the form of pair programming, students get support from peers, and all students benefit. The result for women is higher retention rates (Berenson, Slaten, Williams, & Ho, 2004; Werner, Hanks, & McDowell, 2004).

The evidence is strong that faculty can help retain women in CS. Mentoring for diversity, encouraging persistence, emphasizing homework and academic focus, and creating collaborative learning environments are all ways that faculty members can help prevent women's disproportionate departure from the major.

Advancing and Recruiting Women into Graduate School in Computer Science

Faculty can advance their students to graduate study in computing by mentoring (Cohoon et al., 2004). More than three quarters of faculty members say that they encourage their undergraduates to go to graduate school. But, this action is insufficient for influencing students. Mentoring activities such as helping students learn to conduct research and publish papers are what measurably increase the percent of students who advance directly to graduate school (Cohoon et al., 2004). We have not yet determined whether this effect applies equally to women and men.

Effective recruiting methods are less well-documented than retention methods. The Computing Research Association's 2001 best practices report, "Recruitment and Retention of Women Graduate Students in Computer Science and Engineering," listed 20 expert-endorsed methods (Cuny & Aspray, 2001). Empirical tests have yet to show that these recommendations are effective.

In 2003, we conducted surveys of faculty and students in 48 graduate programs in CSE nationwide (Cohoon & Lord, 2006). Data from this study show that faculty members believe meeting with potential students and encouraging them to enroll is the best way for increasing the number of women graduate students in their program. Our data suggest they are correct that personal contact can be an effective recruiting strategy, but it is seldom employed to promote women's enrollment.

FUTURE TRENDS

There are a number of significant questions that must be answered. Most importantly, we need to learn what leads more faculty members to engage in the behaviors that promote women's entry and persistence in postsecondary computing. In addition, more research and analysis of existing data are needed to identify effective methods for recruiting women.

CONCLUSION

Despite the many factors beyond the control of postsecondary computing departments, there is solid evidence that faculty behaviors can contribute to gender balance. Both the research on women in STEM and research on women in computing provide evidence that faculty members can promote and maintain women's participation.

KEY TERMS

Attrition: Switching to a different major after having declared a computing major.

Computer Science: General computer and information sciences; computer programming; data processing technology; information science and systems; computer systems analysis; and other information sciences.

Gendered Attrition Rate: Result of subtracting the female attrition rate from the male attrition rate to obtain a single measure of the gender gap in attrition rates.

Mentor: Faculty member who may advocate for a student, offer social and emotional support, and provide useful information about how to perform within a university program.

Recruitment: Actively attracting students to declare a major.

Retention: Continued enrollment in a major until graduation.

Role Model: A person who serves as an example of the values, attitudes, and behaviors associated with a role.

Female Perceptions of the Information Technology Culture

INTRODUCTION

In the organizational sciences literature, one of the important social forces that affect the productivity, adjustment, attitudes, and retention of employees is culture. Culture can be defined as the shared philosophies, ideologies, values, assumptions, beliefs, expectations, attitudes, and norms that people have in common with others in a community (Hall, 1959, 1976; Hofstede, 1997; Trice, 1993). Cultures originate as individuals interact with one another. Belonging to a culture involves believing what others believe and doing as they do (Trice & Beyer, 1993). The most obvious manifestations of culture are common language and common ways of thinking (Schein, 1999).

These common ways of thinking are also evident within organizations as employees share basic assumptions on how to do things and solve problems in a way that is considered valid by organization members and, therefore can be taught to new members as the correct way to perceive, think, and feel in relation to those problems (Schein, 1992).

Because culture within organizations is multifaceted, it includes both: the overall culture of the organization as well as subcultures shaped by the specific kind of work that people do in the organization. In contrast to organizational cultures, occupational subcultures arise from the shared educational, personal, and work experiences of individuals who pursue the same kind of work or occupation (Trice, 1993; Trice & Beyer, 1993).

The purpose of this chapter is to present a comprehensive summary of previous studies relating to the concept of occupational subculture of information technologists and the perceptions and difficulties that female students illustrate during their first approaches to the IT occupation. We believe that understanding the difficulties that women face to accommodate to the IT culture can better help academic institutions and industry practitioners develop customized strategies for retention and recruitment of women in the IT field.

BACKGROUND

Occupational cultures have the same characteristics as any culture with a different degree of distinctiveness based on the occupation. Studying cultural characteristics allows managers and academics to develop better human resource strategies that will affect favorable productivity, adjustment, attitudes, and retention of employees in organizations. As stated by Trice (1993) occupational subcultures consist of distinctive clusters of ideologies, beliefs, cultural forms, and other practices that grow uniquely in the context of a particular occupation. Table 1 summarizes the characteristics of an occupational culture based on Trice's theory (Trice, 1993).

THE OCCUPATIONAL CULTURE OF INFORMATION TECHNOLOGISTS

The role of information technology (IT) workers is critical in the development, acquisition, management, use, support, and maintenance of information

Table 1. Summary of the characteristics of an occupational culture

Characteristic	Description
Collective	Cultures are collective, they originate as individuals interact with one another. Cultures are repositories of what their members agree about believing and doing. Belonging to a culture involves believing what others believe and doing as they do.
Emotionally charged	Substance and forms are infused with irrational feelings and elaborate rationales for them. These emotions are propagated through socially accepted channels.
Historically based	Cultures emerge over time but are based on a unique history. The interaction of a particular group in a unique set of physical, social, political, and economic circumstances develops ideologies and forms that are later shared with other individuals who practice those ideologies over time.
Inherently symbolic	Cultures emphasize the expressive side of human behavior. Symbols are the basic unit of cultural expression. Symbols are present everywhere in social life. They can be practically any object, word, act, emblem, dress, etiquette, etc.
Dynamic	Cultures create continuity and persist across generations of members but they are not static. Cultures change constantly. Some of the reasons are the imperfect communication and understanding over time, the individual influences of new members, unconscious transmission, multiple meanings of the symbols of the culture, and the influence from outside.
Inherently fuzzy	Cultures combine contradictions, ambiguities, paradoxes, and confusion. They are also characterized by "enormous multiplicity."
Encourage ethnocentrism	A collectivity may come to be very emotionally attached to a set of ideologies. As a consequence, its culture will be strengthened and the collectivity will come to distrust, fear, and dislike groups with other sets of beliefs. The more emotionally charged these ideas are, the more likely adherents are to be intolerant of those with divergent ideas.
Dysfunctional as well as functional	Strongly held ideologies add to the cohesion among members of an occupation, but at the same time, they make for a rigidity and bitterness toward outside groups, often blocking needed cooperation.
Structure social relations	Cultures, guided by their ideologies, tend to produce mechanisms that arrange the relationship between their members, namely the structure of social relations.

Source: Trice, 1993

technologies and systems. This group of workers with IT skills and knowledge base continually acquired from a variety of formal and informal sources in several specialties, compromise an occupation that crosses and transcends organizations and has its own characteristics. In the 1990s, Duliba and Baroudi (1991) conducted an empirical study in order to identify if the occupational culture of IT workers exists or not. In their study, they concluded that IT personnel indeed form an occupational culture (Duliba & Baroudi, 1991) but back then, this culture did not manifest strong values and cultural forms and instead IT workers formed a weak occupational culture. Because the IT occupation has developed and grown more in the last decade socially and within organizations, recent studies can now better identify the ideologies, beliefs, cultural forms, and other practices that define this community. In other words, we can now identify the features of the occupational culture of information technology workers.

Having that purpose in mind, researchers have recently conducted empirical studies looking for the ideologies, beliefs, cultural forms, and other practices that IT workers manifest (Gerulat, 2002; Guzman & Stanton, 2004; Guzman et al., 2004). Table 2 summarizes the features of the occupational culture of IT workers.

Individuals who are part of the occupation first come into it with values derived from family, school, and community. As they evolve in their occupational communities, individuals go through a process of adaptation where they manifest positive and negative reactions of adjustment to the culture. We were interested in those reactions, particularly the reactions of female individuals who are currently going through a process of occupational socialization in the information technology field. Occupational socialization is the process by which individuals acquire, learn, and adopt the ideologies, beliefs, cultural forms, and practices of an occupational culture. Because the process of occupational socialization begins while individuals are pursuing an academic major, the participants of this study were students of IT related majors who are learning and adopting the ideologies, beliefs, cultural forms, and practices of the IT occupational culture.

Table 2. A Summary of the features of the IT occupational culture

Cultural Characteristics of the IT Occupation
1. The IT culture is elitist, valuing technical knowledge and skill above other values
2. The IT culture is exclusionary because it excludes from membership those individuals who do not possess a sufficiently high level of technical knowledge and skill ranging from the ability to mange IT resources to using IT resources
3. The IT culture views technical knowledge and skill as essential to achieve its informal mission of delivering stable, high-quality computer systems to organizations
4. Normative behavior for this group includes the constant acquisition of technical knowledge and skill in an effort to deliver quality and stable computer systems to the organizations that employ the individual members
5. IT workers frequently use technical knowledge, jargon, and vocabulary as a means of establishing group identity, maintaining boundaries between groups, and excluding out-group members
6. There are extreme and unusual demands pertaining to working in the profession, particularly relating to long hours, angry users, and the need for constant self re-education
7. People in this culture complain about the behaviors and abilities of end-users and about being misunderstood by managers as a form of intra-group bonding
8. A shared sense of satisfaction about helping others with technology that supports and justifies the importance of the occupation is usually present
9. Professional ethnocentrism including feelings of superiority and control over the technology when they solve IT problems
10. Physical settings involving electronic equipment and disorder as signals of group membership
11. Unique and shared stories about the history of information technology as a means of identifying members, validating membership and as a form of intra-group bonding
12. Lack of formal work rules and absence of clear requirements for membership

WOMEN'S PERCEPTIONS ABOUT THE IT OCCUPATIONAL SUBCULTURE

To enhance our understanding of women's perceptions about the IT occupational subculture during the process of occupational socialization, we conducted six focus groups in order to investigate the interaction between female participants and other individuals where they discussed their individual perceptions about the IT occupational culture. Using focus groups as a data elicitation technique there is potential within the group interaction for power relationships to be more greatly diffused, for knowledge to be collectively constructed, and for empowerment, as participants challenge, question, critique and learn from each other (Morgan, 1997; Pini, 2002).

We recruited a total of 46 college students taking IT classes with whom we conducted six focus groups during a period of three months. Focus groups discussions lasted an average of 55 minutes. One of the focus groups was specifically organized to elicit women's perceptions therefore, only women participated. This group had a total of nine women and the moderator was a woman as well.

Our data analysis focused mainly on the responses provided by women. Women's answers were analyzed from the group-grid dimensions' perspective. According to Trice (1993) the group and grid dimensions developed by Douglas (Douglas, 1978) are useful for examining sub cultural relationships because they link culture and behavior in a way that can be observed and determined. "The group dimension consists of the emotionally charged beliefs that organize and maintain ideologies about how to create meaning and control in work life; the grid dimension consists of the tangible structures through which members of an occupation attempt to order their relations with one another" (Trice, 1993).

Based on the group-grid dimensions we found conflictive women's perceptions regarding the IT occupational subculture that we present in the selected most representative excerpts below.

Female IT students do not necessarily view technical knowledge and skills as the most essential value in their occupation. Instead, women value first social instances and interaction with people:

I'm more of a people person rather than just IT.

I want to be an IT professional but I also want to be sociable.

Because of differing primary values, women IT students often get into the IT field based on an extrinsic reward such as diverse application of IT skills or the quick opportunity to get a job due to the high demand. Women IT students also often enter the field in order to comply with other's expectations (i.e., parents) or because they think that having IT skills is a good 'complement' to another more relevant set of skills.

The world is so technological, like everything right now is all about that. Like any job you do has a technology aspect of it.

IT knowledge applies to whatever function of a company or organization.

I'm just doing it because I think it'll benefit me but I don't like it.

I think of it more as a way to advance whatever position you want to do. Like you find a position that makes you happy and use IT as a tool to get to the top. It's something extra that you have in your background over other people that you can use to advance your career.

I was one of the only three girls in the orientation and the other two girls weren't interested. It was obvious their parents were just forcing them into it.

Another aspect about the occupational culture is the physical setting and symbolic representations of the occupation that are negatively described by female IT students. Our participants showed that they relate the occupation as a job where a person is always sitting in a cubicle in front of a computer, and that perception is usually negatively seen:

I do not see myself sitting in front of a computer all day long.

My mom does it [she is an IT person] and immediately things that come to mind are a cubicles and office space where they type away at the screen all day.

Finally, the fact that women are under represented in the IT field generates different kinds of reactions, but women are definitely aware of that. As they mention, this could be taken in their advantage but sometimes it is uncomfortable:

We women in IT are oddballs.

The IT people at my father's office didn't think there were women in the field.

I like being the only girl ... it shows you how the real world is going to be.

FUTURE TRENDS

Given the high demand of information technologists in all types of organizations in the United States and the underrepresentation of women in the IT field, it is important to understand the culture of this occupation in order to customize recruitment and retention strategies for women. We observe that there are some divergences between women's expectations, beliefs, and values that do not correspond to the features of the occupational culture of the IT occupation. Having a better understanding of the culture of the profession as well as the main beliefs and values of women with similar studies like the one presented in this chapter will give academic institutions and industry practitioners better insights into the development of training programs. Since our participants were college students in IT majors, it could be interesting to develop studies that would also identify perceptions of women who have been working in the IT field for several years and see how those perceptions differ from those belonging to participants in our study.

CONCLUSION

It is imperative to know more about the specifics that characterize the IT occupation. Most of the better-known cultural forms in society are negative. Having a clear understanding of all the cultural forms of the IT occupation would allow people to know about the diversity of ideas and activities involved in the profession and reduce conflictive perceptions regarding the IT occupational subculture.

As individuals evolve in their occupational communities, they go through a process of adaptation where they manifest positive and negative reactions to the adjustment of culture. We were interested in those reactions, particularly the reactions of female individuals who are currently going through a process of occupational socialization in the information technology field. Because this process of occupational socialization begins while individuals are pursuing an academic major, the participants of this study were students in IT related majors. However, since data was collected from a small number of individuals, data presented in this chapter should not be interpreted as generally applicable to all women in the IT field. Rather, these results can be viewed as suggestive of the possible explanatory power of the differences of women's perceptions and the cultural values of the IT occupation.

KEY TERMS

Group and Grid Dimensions: These dimensions link culture and behavior in a way that behaviors of people can be observed and determined The group dimension consists of the emotionally charged beliefs that organize and maintain ideologies about how to create meaning and control in work life; the grid dimension consists of the tangible structures through which members of an occupation attempt to order their relations with one another.

Information Technology Job: A predetermined set of activities one is expected to perform within the information technology field.

Information Technology Occupation: A coherent set of jobs that are similar with respect to the type of tasks and training involved related to the development, acquisition, management, use, support, and maintenance of information technologies and systems.

Occupational Community: the group of people with their own occupational culture

Occupational Culture: This term is used referring to an influential occupational subculture outside the organizational context.

Occupational Socialization: The process by which individuals acquire, learn, and adopt the ideologies, beliefs, cultural forms, and practices of an occupational culture. Through this process, individuals learn what is OK and what is not OK to tell and do in a variety of situations related to their occupations (Schein, 2004). This process comprises five overlapping steps: attraction, access, adjustment, identification, and commitment. Occupational socialization is complete when an individual internalizes the value and norms of the occupational group.

Occupational Subculture: The basic assumptions, cultural forms, ideologies, and behaviors that grow uniquely in the context of a particular occupation. An occupational subculture arises from the shared educational, personal, and work experiences of individuals who pursue the same profession and share similar ideologies and forms of expressing those them in speech and behavior.

Female Pupils' Perception of Electrical Engineering

Orit Hazzan
Technion – Israel Institute of Technology, Israel

Ayellet Tal
Technion – Israel Institute of Technology, Israel

Idit Keidar
Technion – Israel Institute of Technology, Israel

INTRODUCTION

Recent studies have focused on gender issues and women's underrepresentation in fields such as computer science, software engineering (Camp, 1997, 2002), and information technology (Varma, 2003). This article broadens the discussion to include the field of electrical engineering (EE), in which the underrepresentation of women is even more salient than in the aforementioned fields. For example, the percentage of female undergraduate students in the Department of Electrical Engineering at the Technion – Israel Institute of Technology (IIT), Israel's leading school of engineering, is less than 15%.

Although there are no easy solutions to the complex problem of attracting women to the field of EE, we argue that certain measures can nevertheless have an impact. Specifically, a partial solution might be to increase the awareness of female high-school pupils, first, to the very existence of the field of EE, and second, to its diverse nature. This article reports on an annual exposure day that aims to do just that. This event, entitled "Electricity in the Palms of Her Hands," specifically targets female high-school pupils who excel in mathematics. This exposure day, the title of which follows the words of a popular Hebrew song, gives the pupils a glimpse of the variety of subfields EE encompasses, and thus gives them a very different perspective on EE as well as a different image of the professionals working in the field.

Specifically, the article examines the perception of EE as expressed by high-school female pupils on two such exposure days. We focus on one main observation: the change the exposure day induces on the pupils' perception of the profession of EE. Our study shows that, whereas in the morning of the exposure days, the pupils perceived EE to be a technical field and did not consider it as a major field of study, by the end of the days, the pupils were describing its multifaceted nature, and many of them perceived EE to be a profession that they might consider studying.

BACKGROUND

The Department of Electrical Engineering at Technion[1]

The Department of Electrical Engineering at the Technion is ranked among the top-10 electrical engineering and computer science departments in the world. It is the largest of Technion's departments, with 1,800 undergraduate students in four main study programs (electrical engineering, computer engineering, computer and software engineering, and electrical engineering and physics), and over 400 graduate students. The department is a center of excellence in both applied and theoretical research. Over 10,000 of the department's graduates hold leading positions in the Israeli hi-tech industries, and they comprise 70% of the chief executive officers and vice presidents of development and engineering in Israel.

F

Women in Technion's Department of Electrical Engineering

The percentage of women studying EE at the Technion is relatively low. In 2002, only 12.3% of the department's undergraduates were women, and that ratio increased only slightly in 2003 to 13% and in 2004 to 14%. The existence of associations in several of the leading universities that aim to provide community, mentoring, and enrichment for graduate women students in EE reveals that a similar phenomenon exists in other universities as well (see, for example, the Women in Electrical Engineering [WEE] organization at Stanford—http://wee.stanford.edu/index.php).

At the same time, achievements of the female EE students are, on average, high. According to Professor Baruch Fischer, former dean of the department (1999-2003), women are equally capable of succeeding in EE studies as are men. "The low representation of women in the department results from the low awareness of what the department offers and what its research areas are, as well as the unjustified 'masculine' image of the profession of EE," said Professor Fisher in the *Technion Magazine* of winter 2004.

In the past 4 years, an attempt is being made to increase the representation of women in the Department of EE's undergraduate programs. The department decided to expose female high-school pupils to the richness and variety of subjects currently studied at the department, to its distinguished research laboratories, to career opportunities in EE, and to pros and cons of being a female electrical engineer. This decision materialized in the form of an annual exposure day entitled "Electricity in the Palms of Her Hands." During the past 4 years, about 400 female high-school pupils, from an array of Israeli high schools, attended these exposure days. During these days, the pupils heard lectures, saw demonstrations, visited laboratories, and met with female graduate and undergraduate students of the department.

The Exposure-Day Format

Table 1 describes the exposure day's agenda. Dr. Ayellet Tal, the second author of this article, formally opens the event. Dr. Tal is a female faculty member of the Department of EE and head of the exposure day's organizing committee. After the dean's greetings, a female undergraduate student describes her experience as a student at the Department of EE. The pupils then listen to a plenary talk on the interrelations among science, technology, engineering, and society. This plenary session increases the pupils' awareness of the facts that (a) women can succeed in EE, and (b) women are still underrepresented in the field of EE.

Table 1. Exposure-day agenda

Hour	Topic
9:00-9:30	**Opening:** Dr. Ayellet Tal, an EE female faculty member, describes her research on computer graphics. Dean gives words of greeting. An undergraduate student describes her social and academic life in the department.
9:30-10:00	**Plenary talk:** Engineering and society
10:00-12:00	**Parallel activities:** Demonstrations and visits to the department's laboratories
12:00-12:30	Lunch break
12:30-13:30	A tour of the Technion campus
13:30-14:15	**Parallel activities:** Meetings with female alumni of the department
14:15-14:30	**Closing session**

The exposure day then proceeds with two sessions of parallel activities conducted in small groups. During the first session, groups of about 20 pupils each visit several of the department's laboratories, hear talks, and see experiments. Each pupil is directed to activities and laboratories related to topics that are close to her own fields of interest.

After a lunch break, each small group of female high-school pupils meets a female alumnus of the EE department. These women alumni represent a wide range of areas in which an electrical engineer can develop a career following graduation. The objective of the meetings is to increase the pupils' familiarity with the actual work of electrical engineers in general, and to expose them to the personal stories of female electrical engineers in particular.

The main ideas emphasized throughout the exposure day are the following:

- **The Interdisciplinary, Multifaceted Nature of the Profession of EE and the Variety of Topics that it Encompasses:** In order to change the vague public image of EE, the exposure day deals with a variety of topics (microelectronics, artificial intelligence, image processing, connections to biology, computer graphics, etc.).

- **The Close Relationship Between EE and Society and Real-Life Applications:** Research reveals that "women, to a somewhat greater extent than men, are apt to choose fields of study they believe will contribute to the social good, and engineering and related sciences are not widely perceived as professions making such contributions" (Muller, 2003, p. 121). Accordingly, women might not choose an EE career if their perception of the field does not include social aspects. For this reason, the exposure day emphasizes applications and products developed by electrical engineers that directly affect everyday life, culture, and art, such as state-of-the-art technologies for picture and music processing.
- **Women's Representation:** The percentage of women who play an active role in the conference is much higher than their overall representation in the department. In addition, these women are from different backgrounds and hold various degrees and positions: faculty members, graduate students, undergraduate students, and alumni. The assumption is that this close interaction with female electrical engineers from different backgrounds has the potential to influence the pupils' perception of the professional lives of electrical engineers.
- **Students' Cultural and Social Lives:** Although learning and professional development are the main goals of students who choose to study at the Department of EE, the cultural, social, and communal aspects of student life cannot be ignored since they may influence the pupils' future choice whether or not to study in a specific department. To illustrate some of the social aspects of life in the Department of EE, the exposure day is held on a day of the week on which the students' arts and crafts fair takes place. As can be seen in Table 1, the conference schedule includes a tour of Technion, which allows for free time to visit the fair, listen to the music, taste the Technion atmosphere, and talk with current students.

MAIN THRUST OF THE ARTICLE

The study described in this article was guided by two main objectives. First, we wished to reveal the pupils' perception of EE. Second, we wished to evaluate how the exposure days can impact this perception. In order to accomplish these goals, we used open questionnaires and ethnographic observations. The questionnaires are presented in Hazzan, Levy, and Tal (2005).

From a comparison of the pupils' written responses given at the end of the day with those given in the morning, it is clear that a change took place during the day and that the pupils reconstructed their perception of EE. As is illustrated in what follows, while in the morning the pupils' preconception of the profession of EE indicated ignorance and a lack of awareness to what EE is, the end-of-the-day perception was focused and addressed the multifaceted nature of the field.

Tables 2 and 3 illustrate the change of perception seen in the questionnaires at the 2003 conference. As Table 2 indicates, only one third of the pupils expressed any meaningful perception of EE in the morning, whereas the other two thirds had either no meaningful answer to give or gave answers that reflected ignorance and lack of awareness. In contrast, when asked again at the end of the day, most of the pupils' answers indicate that during the day they had constructed an academic, engineering, scientific, and human-related image of the profession. Furthermore, at the end of the day, terms that indicate a multifaceted perception of EE were used to describe the profession of EE (e.g., *variety*, *combination*, *broad*, *no limits*).

More specifically, as Table 2 shows, the pupils' perception of EE underwent transformation over the course of the day with respect to three categories. First, the multifaceted nature of the field, barely mentioned in the morning, was mentioned frequently in the pupils' answers at the end of the day. Second, the technical (instrumental) aspect, which was so prominent in the morning, all but disappeared throughout the day. Third, the social aspect, which was not mentioned at all in the morning, emerged at the end of the day. The emergence of the last category is important since, as mentioned earlier, women tend to choose human-related professions.[2]

Table 2. Perception of EE before and after the 2003 exposure day

	Before the exposure day	After the exposure day
Question	No. 5: What do you think EE graduates do when they graduate from Technion?	No. 2: What would you say if you were asked to explain what EE is in two sentences?
Total number of answers	120	45
Number of meaningful answers (%)	44 (36%)	40 (89%)
Elaboration on the meaningful answers	Only two answers addressed the multifaceted nature of EE, e.g., "A combination of several branches that are involved in the invention of instruments in different domains (such as medicine)."	21 answers (50%) described EE as a multifaceted field, e.g., "A huge variety of similar, as well as different, domains that are connected to the society, economy, industry, and to our life in general."
	7 pupils mentioned computers.	18 pupils mentioned computers.
	18 pupils presented the profession of EE as a technical profession, addressing tools and instruments.	3 pupils indicated tools and instruments.
	4 of the above 18 pupils indicated the electricity company, e.g., "They go to work in companies like the electricity company," and "Maybe they go and work as technicians in areas that are related to electricity, etc."	4 pupils specifically indicated that EE is not the electricity company, e.g., "Now I know that it does not mean only working in the electricity company."
	None of the pupils indicated any connection to society or to any other social issues.	5 pupils indicated social issues, e.g., "A kind of engineering that is manifested in electrical products and contributes to the quality of life."
Number of non meaningful answers (%)	76 (64%)	5 (11%)
Examples of meaningless answers	"Engineering electricity," and "Look for a job in companies in which electrical engineering can work."	"I can't explain it in two sentences." *

*Note: *This answer might also be interpreted as a reflection of the idea that EE is too rich to be described in two sentences.*

Table 3. Activities performed by electrical engineers: Pupils' perception before and after the exposure day

	Before the exposure day	After the exposure day
Question	No. 5: What do you think EE graduates do when they graduate from Technion?	No. 3: List at least three things that people who work in EE do when they graduate from Technion.*
Number of answers	120	39
Areas in which electrical engineers work	10 general areas were mentioned, such as research and development (19 pupils), and hi-tech (18 students, e.g., "Work in hi-tech companies").	20 areas were mentioned; 11 of them were specific areas presented during the exposure day (e.g., robotics, image processing, artificial intelligence).
Indication of specific topics	Only 4 pupils indicated a specific topic such as robotics.	37 out of a total of 84 items mentioned were specific domains to which the pupils were exposed during the day.
Teaching	2 pupils mentioned teaching (e.g., "Work as teachers or in companies for engineering of electricity").	9 pupils indicated "academic teaching."
Technical image	18 pupils mentioned instruments and/or the electricity company (e.g., "Build electrical circuits for instruments," and "Engineering machines, prepare the electrical systems in buildings, etc.").	No technical or tool-oriented answers were given. Only 1 pupil mentioned the electricity company.

*Note: *It may be the case that had the pupils been asked also in the morning to mention three items, their morning answers would be more focused. Still, these answers would probably be general in nature.*

Table 4. Possible future studies at Technion's Department of EE

Would you consider studying at Technion's EE Department?	2003		2004	
	Morning (N=124)	End of the day (N=44)	Morning (N=86)	End of the day (N=56)
Yes	19 (15%)	29 (66%)	22 (26%)	46 (82%)
No	50 (40%)	11 (25%)	28 (33%)	7 (13%)
Maybe	52 (42%)	4 (9%)	33 (38%)	3 (5%)
N/A	3 (2%)		3 (3%)	

Table 3, which addresses typical activities associated by the pupils to electrical engineers, adds another dimension to this process of perception changing. More specifically, while in the morning pupils' descriptions tended to be vague and general, much more specific and concrete descriptions were exhibited at the end of the day. Furthermore, Table 3 reveals that on the afternoon questionnaire, a greater proportion of pupils mentioned a wider variety of specific areas in which electrical engineers work compared with the morning questionnaire, and that the predominantly technical image of EE was transformed over the course of the exposure day. Moreover, from among the 20 domains mentioned by pupils in their afternoon answers, 13 were mentioned by more than one pupil. The most frequently mentioned domains were software and hi-tech (appeared in 23 answers, 16 of which mentioned the names of well-known companies, such as Intel and IBM); research (10 answers); and academic teaching, robotics, and electronics (9 answers each).[3] Similar observations were found in the 2004 conference (Hazzan, Tal, & Keidar, in press).

This image change may explain the reduction in pupils' resistance toward the idea of studying EE as a major field of study, as presented in Table 4. In both the 2003 and the 2004 conferences, a considerable increase in students' interest in the department was observed. Specifically, this interest increased during the 2003 conference from 15% in the morning to 66% by the end of the day; during the 2004 conference, interest increased from 26% to 82% (Table 4).

FUTURE TRENDS

In order to study the long-term influence of such exposure days, we plan to examine the way in which the female high-school pupils who attended the exposure days will perceive EE at several future points in time. Such an exploration will help refine observations and recommendations about the preferred way in which the profession of EE should be presented to a female audience that is not familiar with the nature of the profession.

CONCLUSION

The aim of the study described in this article was to examine the perception of EE by female high-school pupils at the beginning and at the end of an exposure day organized by the Technion's Department of EE. The rationale for the day stemmed from the very salient underrepresentation of women among the undergraduate students and graduate students in the department.

We derive two major conclusions from this study with respect to the way in which the profession of EE may be presented when the objective is to attract more women to the field.

First, as in the case of computer science, the profession of EE seems to suffer from a misconceived image among the public. In the case of computer science, many people think that to be a computer scientist means sitting in front of a computer screen all day long, without communicating or socializing with other people (Margolis & Fisher, 2002). In the case of EE, from the pupils' responses at the beginning of the day, we learn that their image of EE was very technical and that they were unaware of the social, scientific, and multifaceted nature of the field. The exposure day described in this article shows that this image can be changed in a relatively short period of time, provided such a day is well organized so as to include the relevant ingredients that inspire a more realistic image of the profession. Specifically, we argue that emphasis should be placed on the multidisciplinary nature of the field in general, and on the direct influence of this trait on society in particular.

Second, we suggest exposing the pupils attending such a day to female role models. Such exposure enriches the image of the profession by adding the individual perspective of the profession to the more global perspective that was explained in the previous paragraph.

ACKNOWLEDGMENT

We would like to thank the Samuel Neaman Institute for Advanced Studies in Science and Technology and the Technion Fund for the Promotion of Research for their generous support in this research.

KEY TERMS

Artificial Intelligence: The field concerned with making computers behave like humans. The term was coined in 1956 by John McCarthy at the Massachusetts Institute of Technology.

Computer Engineering: The application of engineering principles and methods to the design and development of hardware systems. (http://www.hpcc.gov/pubs/blue94/section.6.html)

Electrical Engineering: Electrical engineering is one of the broadest of the engineering disciplines. It deals with electronics, computers, and communication. The professional activities of electrical engineers directly affect the everyday lives of most of the world's population.

Image Processing: The field concerned with analyzing and manipulating images with a computer.

Multimedia: The use of computers to present text, graphics, video, animation, and sound in an integrated way.

Robotics: The field concerned with creating robots: devices that can move and react to sensory input. Robotics is one branch of artificial intelligence.

Shrinking Pipeline: The pipeline represents the ratio of women involved in computer science from high school to graduate school. The pipeline shrinkage problem focuses on several exit junctions: from high school to undergraduate school, at the bachelor's level, and at the seniority levels both in academia and the industry.

Software Engineering: The application of engineering principles to software. It applies principles of computer science and mathematics for the development, operation, and maintenance of software. Software engineering addresses not only the technical aspects of building software systems, but also social, management, and cognitive topics.

ENDNOTES

1 For additional details, visit the department's Web site at http://www.ee.technion.ac.il/.

2 The drop in the number of responses between the survey at the beginning of the exposure day and the responses after the exposure day is due to the fact that the transportation organized by several schools had left before the day ended.

3 In addition, lasers was mentioned six times; image processing, computerized graphics, or animations was mentioned five times; and information processing, film dubbing, and machines were each mentioned three times. The following domains were mentioned only once: multimedia, biomedicine, artificial intelligence, the electricity company, cellular-phones companies, and job seeking.

Female Retention in Post-Secondary IT Education

Jeria L. Quesenberry
The Pennsylvania State University, USA

INTRODUCTION

The historical gender stratification in technical disciplines has been an area of study for many years and researchers have concluded that women are alarmingly under-enrolled in post-secondary information technology (IT) education (e.g., Camp, 1997; Teague, 2002; von Hellens, Nielsen, Greenhill, & Pringle, 1997). One challenge facing the IT gender gap discourse is the application of theories that focus on a variety of levels of analysis (Korpela, Mursu, & Soriyan, 2001; Walsham, 2000). Recently, the Individual Differences Theory of Gender and IT has been proposed by Trauth (Trauth, 2002; Trauth, Huang, Morgan, Quesenberry, & Yeo, 2006; Trauth & Quesenberry, 2006, 2005; Trauth, Quesenberry, & Morgan, 2004) to explain the underrepresentation of women in the IT workforce at both the societal *and* individual levels of analysis. To date, the majority of the Individual Differences Theory of Gender and IT research has focused on improving our understanding of the underrepresentation of women in the IT workforce.[1] Hence, in an attempt to build on the theoretical foundation, this article reports on a literature survey of the influences on American women's retention in post-secondary IT education.

BACKGROUND

Walsham (2000) stresses the importance of research agendas that help to improve the understanding of IT in the contemporary world. Hence, researchers should investigate IT that enables connectivity, but supports diversity by studying particular levels of analysis in detail and context including: the individual, group, organization, inter-organization, and society levels. Korpela et. al. (2001) also support the level of analysis concept by constructing a 2x4 + History framework, which contains four integrative levels of analysis: the individual, group/activity, organizational, and societal levels.

The Individual Differences Theory of Gender and IT articulated by Trauth (Trauth, 2002; Trauth & Quesenberry, 2006, 2005; Trauth et al., 2004, 2006) answers the call for research at multiple levels of analysis stressed by Walsham (2000) and Korpela et al. (2001). First, the theory focuses on women as individuals, having distinct personalities, experiencing a range of socio-cultural influences, and thus exhibiting a range of responses to the social construction of IT. As a result, the theory focuses on an individual level of analysis while acknowledging gender group and societal influences. Secondly, the Individual Differences Theory of Gender and IT takes into account the role of gender group and societal shaping and the importance of individual critical life events (Trauth, 2002; Trauth & Quesenberry, 2005, 2006; Trauth et al., 2004, 2005a).

This theory accounts for the differences among women in the ways they experience and respond to the IT workforce using three constructs: personal data, shaping, and influencing factors and environmental context (Trauth et al., 2004). The personal data construct includes: demographic data (e.g., age, race, and ethnicity), lifestyle data (e.g., socio-economic class and parenting status), and workplace data (e.g., job title and technical level). The shaping and influencing factors construct includes: personal characteristics (e.g., educational background, personality traits, and abilities), and personal influences (e.g., mentors, role models, experiences with computing, and other significant life experiences). The environmental context construct includes: cultural attitudes and values (e.g., attitudes about IT and/or women), geographic data (about the location of work), and economic and policy data (about the region in which a woman works).

MAIN THRUST OF THE ARTICLE

A literature survey of gender and IT research was conducted to understand how individual attributes contribute to the retention of females in post-secondary IT education in support of the Individual Differences Theory of Gender and IT (Trauth, 2002; Trauth & Quesenberry, 2005, 2006; Trauth et al., 2004, 2006). This analysis resulted in the identification of several research themes that influence women in IT education. These themes include: personal attributes, learning experiences, and responses to support structures and will be discussed in more detail in the remainder of this section.

Personal Attributes of Students

Researchers have found that self-confidence has a large influence on female retention in post-secondary education (Alper, 1993; Ambrose, Lazarus & Nair, 1998; Beckwith, Burnett, Wiedenbeck, Cook, Sorte, & Hastings, 2005; Vest & Kemp, 1999). Shashaani (1994) argues that there is a direct connection between informal computing experiences and high levels of self-confidence in using and understanding IT. This notion is articulated by Margolis and Fisher (2002) in their argument that men tend to have more informal computing experiences than women at the post-secondary level. As a result, male students generally have higher levels of computing self-confidence than female students. Over time, this causes female students to question their technical knowledge and personal fit with an IT related degree, eventually leading to lower female retention numbers.

Research has also demonstrated that negative images of the IT workforce have an influence on the retention of women in post-secondary IT education (Ahuja, Robinson, Herring, & Ogan, 2004; Balcita, Carver & Soffa, 2002; Camp, 1997; Nielsen, von Hellens & Wong, 2000; Vest & Kemp, 1999). Joshi, Schmidt, and Kuhn (2003) and Camp (1997) explain that both men and women acknowledge the negative stereotypes of IT work (e.g., IT work is solitary and a male domain). Furthermore, these stereotypes persist despite receiving accurate information about IT careers (Joshi et al., 2003). Balcita et al. (2002) argues that these negative stereotypes are shaped by the media, and society, which frequently present the IT domain as a place that does not welcome feminine characteristics or traits. For instance, television shows such as *Bill Nye the Science Guy* and *Mr. Wizard* demonstrate strong male presence in science, but lack female role models with whom women can identify. As a result, women, more than men, leave post-secondary IT education programs because they cannot imagine their roles within the field.

Student Learning Experiences

Barker, Garvin-Doxas, and Jackson (2002) and Katz, Aronis, Allbritton, Wilson, and Soffa (2003) argue that experiences in learning environments also have an influence (positive and negative) on female retention in post-secondary IT education.[2] These authors found that the influences of impersonal environment and guarded behavior, informal student hierarchy, and the creation of a defensive social climate are the most important factors in student retention. For instance, Barker et al. (2002) observed that technical courses in post-secondary IT education have the tendency to be impersonal social environments in which it is easy for students to remain relatively anonymous and socially distant. The authors found that it was rare to hear the names of students or the sharing of personal information among students and professors in technical classes. Students in these technical courses were typically referred to as “the woman in the red shirt” or by desk location such as “F1.” In addition, informal hierarchies were created by the attainment and display of status in social structure of the classroom. In these technical courses, status was afforded to those students who displayed the highest level of technical skills. Students with programming experience were frequently referred to as “smart” and it was implied that they had intellectual superiority over the other students. Eventually, students became aware of whether they belonged in the group and their places in the social hierarchy. Unfortunately, the female students felt as outsiders and did not share social hierarchy with their male counterparts.

Table 1. Gender and IT education sub-category constructs

High Level Construct	Sub Category Construct
Personal Data	
School Place Data	Student Learning Experiences (Environment and Classroom) Student Support Structures (Faculty, Role Models and Mentors for Students, Institutional and Community Response)
Shaping and Influencing Factors	
Personal Characteristics	Personal Attributes (Student Self Confidence, Student Images and Stereotypes of IT)

Support Structures of Students

Researchers have found that role models and mentors constitute a powerful support structure that has a positive influence on the retention of females in post-secondary IT education (e.g., Beise et al., 2000; Symonds, 2000; Vest & Kemp, 1999). Role models provide confirmation that women can succeed in technical disciplines and encourage their persistence in the program (Cohoon, 2001, 2002). Mentors are also a powerful support structure that influence the retention of women in IT education. Mentors provide encouragement in a genuine and sincere manner that transforms the way a woman views her connectedness to a technical discipline (Townsend, 2002).

Having faculty who enjoy teaching is also an important influence on the retention of women in post-secondary IT education. Departments with faculty reporting high degrees of personal satisfaction tend to have lower student attrition rates (Cohoon, 2000, 2001, 2002). Quality teaching helps overcome the disproportionately negative effects of unfavorable environments. Female students can also be influenced by accessible and motivated teachers. Faculty who promote interactions among classmates and develop learning communities and other forms of peer support for students also have an influence as they help to foster friendship and support networks that provide effective retention of women in technical programs (Ahuja et al., 2004; Cohoon, 2002).

Institutional and community resource support also has an influence on the retention of females in post-secondary IT education. Educational programs with adequate resources and student organizations, the use of the local job market, and volunteer opportunities all contribute to increased retention rates. The more support women receive from institutional and community resources the higher the female retention level of IT educational programs. Likewise, programs with strong institutional support and adequate resources have a positive influence on the retention of female students (Cohoon, 2002; Frieze & Blum, 2002).

IT educational programs with active student organizations also have a positive influence on the retention of female students in post-secondary IT education (Frieze & Blum, 2002; Gabbert & Meeker, 2002). For example, at Carnegie Mellon University a student leadership advisory council called the Women@SCS Advisory Council was formed to build a community to act as the driving force behind proactive efforts to improve the academic and social climate for women in the computer science department. The Council holds various mentoring events and activities such as freshmen orientation, Big Sisters/Little Sisters, school help sessions, dessert study breaks, invited speaker series, conferences, and outreach programs. As a result, the Council fosters a supportive community that promotes the academic success of women in computer science by improving the academic and social climates (Frieze & Blum, 2002).

FUTURE RESEARCH

This article has discussed several factors that influence the retention of women in post-secondary IT education in order to build on the Individual Difference Theory of Gender and IT. This analysis has attempted to go beyond the identification of societal messages that operate at the group level of analysis to also understand the variances at an individual level of analysis. In doing so, several sub category constructs have been added to the conceptual framework of the Individual Differences Theory of Gender and IT (see table one).[3] Future research plans include the continued building of the Individual Differences Theory of Gender and IT to more fully account for gender and IT education issues in order to conduct empirical investigations.

CONCLUSION

The concerns of IT worker shortages and the importance of diversity as a key component of the American economy highlight the utmost importance of attracting more women to IT careers. An initial step in this process is to recruit and retain more female students in IT educational programs and in the IT workforce. In order to do so, it is important for researchers, policy makers, and practitioners to understand the factors that influence women's choices to pursue IT degrees. The factors that have been elucidated in this article can be leveraged when recruiting and marketing to potential students as a way to encourage more women to consider a technical curriculum. They can also be used to reshape educational institutions and the IT workforce to better accommodate female recruitment and retention.

KEY TERMS

Conceptual Framework: The basic structure of concepts of a given theoretical perspective.

Individual Differences Theory of Gender and IT: A social theory developed by Trauth (2002; Trauth et al., 2004) that focuses on within-group rather than between-group differences to explain differences in male and female relationships with information technology and IT careers. This theory posits that the underrepresentation of women in IT can best be explained by considering individual characteristics and individual influences that result in individual and varied responses to generalized environmental influences on women.

IT Education: Educational programs including, but not limited to computer science (CS), management information systems (MIS), information sciences and technology (IST), and computer engineering.

Level of Analysis: Research agendas and projects in various domain areas of individuals, groups, organizations, inter-organizations, and societal levels (Walsham, 2000).

Post-Secondary Education: University or college educational experiences, which follows secondary education such as high school.

ENDNOTES

1. For instance, the influence of environmental context in the underrepresentation of women in the IT workforce (Trauth et al., 2005), the role of parenthood (Quesenberry et al., 2004, 2006) and ubiquitous computing in work-life balance (Quesenberry & Trauth, 2005), and the role of social networking in the IT profession (Morgan et al., 2004).
2. The learning environments include the physical surroundings, psychosocial conditions, emotional conditions, and social or cultural influences present in a learning situation (Barker et al., 2002).
3. The full conceptual framework for the Individual Differences Framework can be found in Trauth et al. (2004).

Females on Technology Courses in UK Colleges

Sheila French
Manchester Metropolitan University, UK

Diane Saxon
City College Manchester, UK

INTRODUCTION

This article reports the findings of a funded research project carried out in two further education (FE) colleges in the North West of England. The under-representation of women in the technology sector has been the focus of various initiatives in the United Kingdom (UK) over the last 30 years, and FE, with its emphasis on vocational and practical skills, could be seen as an effective route to redress this imbalance. However, data from colleges continues to show that student females are also under-represented on technology courses in the sector. The project is seeking to gain a greater understanding of the experiences of young women on a number of technology courses where the majority of students are male. The outcomes of the research are intended to inform the FE colleges' developing strategies on how to improve the recruitment and retention of females, so helping to redress the gender imbalance on the technology courses in the study.

Research studies of this nature are rare in the FE sector, as it is largely a neglected field of study for educational research in gender and technology. In this project, we provide a forum in which the experiences of the female students in the sector can be discussed. The research focuses on the young women who "have arrived" and are currently studying technology subjects in the colleges. We report that gendered notions of technology courses still prevail and these have an impact on the choice of course, progression to technology industries and issues of confidence with technology. Overall, we highlight some of the issues that make the female students' experience of occupying "male spaces" an uncomfortable one.

BACKGROUND TO THE STUDY

This research is based on the experiences of women in business and creative technology courses in two large general FE colleges in the North West of England. The FE sector in the UK provides education and vocational training for the post-16 age group. It is the largest sector in UK education, with more than 6 million learners, and is seen as "the engine room for skills" of the UK workforce (LSC, 2005, p. i). The emphasis is on vocational study, and its population includes both 16-19 year-old learners and adult learners as part of the UK government strategy of lifelong learning.

In this article, we report on the positive choices to study technology courses made by the young and mature women who participated in our study and their subsequent experiences. The study has investigated the rationale for our students' choice of subject as well as their future career aspirations, their confidence with technology and their experiences of studying in a field that has a "dominant masculine culture and how these factors influence their participation and progression in that field.

Theoretical Framework

The context of this research lies in the well-documented under-representation of girls and women in the field of IT education generally. Evidence shows that in spite of repeated initiatives to encourage women into technology, males dominate the use of technologies in all areas of society (Benn, 2004; EOC, 2004; DfEE, 2001; Connolly & Hellawell, 2001; Wilkinson, 2001). Despite a growing trend of women's increasing participation to higher education in the last 10 years, in 2001, only 21% of undergraduates taking a first degree in computing, engineering or technology subject areas in the UK were women. While the UK government is launching new initiatives to attract more women to information technology industries, occupational segregation prevails in many areas associated with technology (EOC, 2004). The Equal Opportunities Commission (EOC, 2004) recently reported that the current proportion of women working in information and communication technologies (ICT) occupations is 15%, and in the spring of 2003, 151,000 women were working in ICT occupations, compared with 834,000 men. Continued occupational segregation restricts the pool of likely candidates and damages Britain's competitiveness as it continues to contribute to skills shortages (EOC, 2004).

Social studies of the relationship between gender and technology are well developed and demonstrate the complexities of researching in this area. Researchers adopt several theoretical and methodological positions. Some provide evidence that technology is not gender-neutral (Cockburn, 1985; Wajcman, 1991, 2004; Woodfield, 2000). Others argue that the dominant discourses around the use and implementation of ICTs are masculine (Clegg & Trayhurn, 1999; Clegg 2001; Grundy 2003), and that "computers, like cars and other forms of hardware, constitute a naturalised part of male heterosexual identity" (Clegg, 2001, p.314). No matter which way we interpret the findings, the situation remains less than optimistic and, as Wajcman points out, "the connection between masculinity and technology, reflected in women's under representation, is still pervasive" (Wajcman, 2004).

Existing research tends to concentrate on females in higher education, but it is clear (Ball, Davies, David & Reay, 2003; David, Ball, Davies & Reay, 2003) that gendered notions are formed earlier than this, and this limits the numbers of females applying to technology courses. Students from FE colleges make up a significant percentage of applicants to university courses, and it is therefore important to explore the rationale for students' choice of subject and their future career aspirations. Furthermore, we want to explore how issues of confidence with technology and the experiences of studying in a field that has a "dominant masculine culture" affected those career aspirations.

THE CASE STUDY

Table 1 lists the selected courses and student numbers by gender for the years 2002-2003 and 2003-2004. More information about the courses can be found in the Terms section.

The table shows that the gender imbalance persists to higher and lesser degrees depending on the course and the focus on technology; it would appear that where there is a greater emphasis on technology on the course, there are fewer female students.

Table 1. Enrolments on technology courses

Course name	Level	% Female students 2003-04	Total students 2003-04	Females 2003-04	% Female students 2002-03	Total students 2002-03	Females 2002-03
College 1							
ICT GNVQ Foundation *	1	31%	39	12	20%	41	8
ICT GNVQ Intermediate *	2	21%	48	10	17%	35	6

ND for IT Practitioners*	3	17%	23	4	26%	31	8
AVCE ICT *	3	27%	11	3	17%	23	4

Methodology

The main focus of the data collection methods was semi-structured interviews with female students nearing the end of their program of study. The research team was led by two researchers, one from the higher education (HE) sector and the second from the FE sector, together with several FE tutors who worked closely with the students. A total of 32 interviews were conducted, made up of 10 general national vocational qualification (GNVQ) intermediate, 5 GNVQ foundation, 10 advanced vocational certificate of education (AVCE) IT, 3 music technology, 4 music and new media management.

Additional background data was collected by surveying full cohorts of students, both male and female. The asterisked courses in Table 1 are courses where students completed the survey questionnaire. Survey response rates were close to 100%, as questionnaires were distributed and filled in during tutorial sessions.

Previous studies of post-16 groups have found that educational choice is related to cultural and social background, with links to ethnicity and class (Ball et al., 2003), and that gender issues are highly significant in the processes of choice of higher education (David et al., 2003). Parents, teachers, guidance advisors and peers, as well as the students' likelihood to do well in a particular subject, are all cited as factors which influence student choice (McGrath & Millen, 2003). In choosing technology courses, teachers' and parents' attitudes toward technology subjects are said to influence decision making. In our study, many suggested that their parents were important in influencing their choice of course, although there was no noticeable difference in the strength of influence of mother or father.

My mum encouraged me to go to college, I tried hairdressing on the choices course for six weeks and didn't like it so I preferred IT. (GNVQ Intermediate student)

Other students had "fallen" into IT by purely by accident. It has been reported elsewhere that the reluctance of girls to embrace the computer has been perceived as a problem of girls' confidence; others suggest that girls make conscious choices to reject the subject (e.g., Wilson, 2003). Knowing about a course or prospective career is obviously an important issue. One of the Music Technology students who is a mature student, age 23, commented that she had not chosen the course earlier because "No one presented it to me," (Music technology student—level 3).

All the students interviewed had met either the course leader or one of the tutors at their interview. We were surprised to hear the comments of one of our female students about the course she was about to embark on (IT AVCE).

I couldn't believe that he [male tutor] said, 'It was a lad's course.'

She went further to say,

There were a lot of girls being interviewed at the same time as me, but they didn't come on the course.

The girls were asked why they didn't think females enrol in technology courses. Just two examples of results were:

Not interested because it's a boy thing,

and

A lot of girls think it's too technical and that they wouldn't be able to do it.

However, experiences were not always negative:

The course leader (male) encouraged me to enrol, and so I did. (Music technology—level 3)

Course Culture: Girls in Boys' Spaces

In both colleges, female tutors and course leaders were in the minority. Most personal tutors were male, and a common comment was: "I would rather have a woman to talk to" (GNVQ intermediate student). Some of our students found that working in a predominantly male student group presented "problems" or "perceived" problems, some of which had severe consequences on their course choices, as exemplified by this comment:

I could have gone straight onto the AVCE Advanced course but there were no other girls on the course that year so I did an extra year on the Intermediate course (GNVQ) so that I would have some female company. (AVCE student)

This decision has major implications for the student's future and questions how girls' perceptions or their actual experiences of working with male students might influence their career choices and academic progression. It leaves us to ask, how many other girls have made a similar choice or been influenced in this way?

Another student commented that as a female you needed to be "confident, brash and then you won't get beaten by them" (GNVQ intermediate) and "you have to push yourself and make your voice heard." (GNVQ intermediate). It is clear that female students have to be different or find a way to "fit" into this male domain. We were surprised to find that not one of the students who were studying at level 2 said they intended to pursue a career in technology. More seriously, their current courses did not appear to be changing their minds.

Confidence with Technology

We know from examination results and comments from tutors that girls often do better than boys on technology courses, but often, the girls themselves don't believe this. In the study, we found that many of our female students, particularly on level-2 courses, perceived that they lacked confidence with technology and even that they were "less able" than the boys. They often told us that boys were better at using technology than girls. At this level, there was little sense of boys helping the girls to do the work or improve their skills, and indeed, little sense of integration of males and females. Several female students said they struggled with the technical aspects of their courses. However, a few were more positive and said that their confidence in using technology had increased during the course.

Level-3 female students were more confident in their use of technology, although one student described herself as "weird" because she was good at using technology. Another level-3 student commented that her male friends were always there (in the studio) "instantly at the technology" and she claimed that, as a female, it was "easy to take a back seat," but suggested she was different in that she was "quite forceful," suggesting she pushed her way in.

FUTURE TRENDS

The study has revealed a number of factors that affect our students in technology courses. Students' first impressions are gleaned from the way the course is described and presented in the college literature. The application and interview processes may reinforce these impressions and we have seen they can sometimes meet with discouragement and negative messages. We have seen that these can continue into the courses themselves, where our female students find males seriously outnumber them, a lack of positive female role models and a male-oriented and -dominated culture.

As Grundy (2003) suggests, we should look more closely at how we describe the subjects to potential students both verbally and in the course literature. We would also suggest that initiatives to inform parents, career advisors and subject teachers are used to ensure that those who advise our potential students are fully informed about the technology courses and career choices open to young women. Such steps might combat some of the gendered perceptions that our students suggested were still held by most of their peer group. Taster sessions are common in colleges to attract students, but colleges may need to provide taster sessions or college days specifically aimed at girls.

Other issues are more problematic; for example, we see a self-perpetuating cycle of a lack of female role models contributing to fewer students being interested in technology and, therefore, not interested in pursuing technology as a career choice. This inevitably reduces the availability of potential female role models for the future.

Equally if not more problematic is how to change the "lads' culture" of the courses. This is not new to technology courses or to the computing industry, where it is said that the jargon and culture of the subject of IT and computing excludes females (Grundy, 2003; Woodhead, 2002). There is no doubt that our findings suggest that there are still very gendered perceptions of these courses, implying that they are male spheres. These gendered perceptions extend to career advisors and to parents, many of whom have little experience of technology and the huge range of related careers. Our findings leave us feeling that technology courses in colleges are uncomfortable places for the young women in our study. To change this is a formidable task, but we can make some suggestions, such as positive action to educate career and student advisors, ensuring that female tutors are teaching in the courses; and the implementation of strategies to manage "laddish" behavior of the boys in class to make the young women in these courses feel more comfortable. We must ensure female students have equal access to technology and that measures be taken to ensure their confidence in using technology is built from the start of the course.

The colleges intend to act on the outcomes of the study and carry out further research with female students. As we have said, very few of the girls in our study will either progress to higher levels or end up working in a career associated with technology. The girls' career choices are likely to reflect their experiences on these courses; again, they must be encouraged and informed about choices available to them for future progression. A few students clearly have enjoyed their subject and intend to pursue a career in a technology industry. We call for more positive action from the career advisors and technology industries to inform young women of the range and potential of the careers available to them.

CONCLUSION

The study has provided a case study of practice that helps to explain the low levels of female participation and success on a range of technology courses in two FE colleges. Most importantly, it has revealed the experiences of female students as they study in the courses. Furthermore, the study adds to the small but growing number of qualitative studies in the UK FE sector, and therefore supports policy initiatives to raise the research profile of the sector and its practitioners.

In this short article we have presented only an outline of our research. The women we have interviewed come from a variety of backgrounds and previous experiences, yet they report similar feelings and experiences about the courses. The under representation of females in the courses clearly needs to be addressed. However, we fear that until the prevailing masculine cultures around "technology" courses—which suggest that technology has little to offer to young women—are tackled, these courses may remain perceived as "boys courses" by both male and female students, thus perpetuating their male-oriented culture.

KEY TERMS

Business and Creative Technology: The definition of business and creative technology courses in this paper encompasses business IT/computing courses, music technology and graphic design courses. In all of these courses, the design and use of ICT is an integral part. Details of courses are below:

- **AVCE:** The advanced vocational certificate of education. Two-year, level-3 general IT course providing progression into higher education, employment or related qualifications.
- **BTEC National Diploma:** Level-3 IT course providing progression into higher education, employment or related qualifications.
- **GNVQ:** General national vocational qualification. An intermediate, level-2 qualification equivalent to five GCSEs, giving entry to the AVCE level-3 qualification.
- **Higher National Diploma:** Two-year, full-time course allowing entry into the second or third year of a degree course.

Further Education Sector: Provides vocational and academic education to post-16 learners.

Higher Education Sector: Provides academic education to the post-18 age group.

Masculine Culture: Sees technology in its widest sense, such as cars and other forms of hardware, as a naturalized part of "male heterosexual identity" (Clegg, 2001, p. 314) in which the jargon and culture of IT and computing excludes females.

Occupational Segregation: Involves both horizontal and vertical segregation. Horizontal refers to when a given gender dominates an occupation where there is little or no noticeable engagement in non-traditional occupations for women, such as engineering and computing. Vertical segregation refers to limited career progression, with women generally in the lower grades (EOC, 2004).

A Feminist Agenda for Reducing the Gender Digital Divide

Gillian M. Marcelle
SPRU University of Sussex, UK and Technology for Development, South Africa

INTRODUCTION

There is little shared understanding of the term "digital divide," but this has not prevented the international community from investing a great deal of effort in projects that aim to reduce the digital divide by reducing disparities in access to information and communication technologies (ICT) (European Commission High Level Group, 1997; International Telecommunication Union [ITU], 1984, 2003; United Nations Economic and Social Commission [UN ECOSOC], 2000). The divergent rate at which ICT diffuses—the digital divide—is a reflection of broader socioeconomic divides, many of which exist within societies. The divide between men and women, rich and poor, young and old, urban and rural, literate and non-literate, also manifests itself in the digital world of media, computers, telecommunications, Internet, and jobs in software production. Information and communication flows carried by ICT are increasingly becoming an integral factor in international, institutional, and political processes. Lack of access to ICT therefore impacts on opportunities for developing countries' economic growth, wealth distribution, social empowerment, and development. It is the digital divide which largely prevents the equal sharing of knowledge worldwide and leads to "information and knowledge poverty" among certain groups. If only a select number of countries, and within them certain groups, reap the benefits of ICT while others continue to lag behind, the digital divide will continue to grow and the virtuous cycle that ICT can create will not be enjoyed by many (Millward-Oliver, 2005).

There is little acknowledgment and even less acceptance that gender constitutes an important influence in the structure of the "digital divide." At first glance, this failure to admit context may seem strange and out of step with common sense. Why should gender relations, such an important and pivotal element of social structure, that is known to influence differentiated access to financial resources, employment opportunities, education and training, water and sanitation, health care, legal status, and enjoyment of human-rights not affect access to and control of ICT? This article will explore some of the key factors that lead to gender blindness in the digital divide debate and articulate a strategic response.

ROOT CAUSES OF GENDER BLINDNESS

The first is the prevalence of the myth of *technology neutrality*. Despite evidence and academic theorising related to the social construction of technology (see, for example, MacKenzie & Wajcman, 1995) in the ICT sector, the prevailing dominant culture of scientists, technologists, and policy makers insists that ICT are universally beneficial *tools.* Although this dominant narrative flies in the face of research and lived reality, this tendency is well and truly entrenched in the mainstream of the ICT sector, and has been accompanied by hyperbole about the unprecedented contribution that ICT can make to all our lives. What is more, the assumption of technology neutrality sits as one of the unquestioned bedrocks of much ICT policy making and programming, including in the efforts of multilateral organisations that ought to know better (European Commission High Level Group, 1997; Department for International Development [DFID], 2002; ITU, 1984, 2003; Organisation for Economic Cooperation and Development [OECD], 2003; UN ECOSOC, 2000; UNDP, 2003; World Bank, 2002, 2004), especially given their rhetorical commitment to "mainstream" gender equality.

The second factor has to do with differential access to power and influence in the ICT sector. Women are significantly underrepresented in positions of power and influence within ICT producer firms, policy making institutions and knowledge centres. Men in those positions have not worked very hard as champions of gender equality. As a result, the promotion of gender-equality in ICT is not a priority. For both men and women in the ICT sector, paying attention to gender equality issues is not considered to be an issue that leads to career advancement and certainly does not dominate real politic and tough negotiations (Marcelle, 2000a, 2005). Gender analysis confirms that over the last decade (Hafkin 2002a, b; UN-DAW, 2003) those with power and influence do not consider and give priority to gender-equality in ICT policy. The issue either falls off the list completely, or is included with tokenism and patronisation when the influential bodies set out the determinants of ICT policy (G8 Dot Force, 2002; Gilhooly, n.d.; World Bank, 2002; WTO, 1998). This applies to both the international and national levels; in the latter, gender-equality machineries are often not considered to be important contributors in defining an agenda for the Information Society. Further, there is also a disparity in access to financial and human resources. For the most part, gender-equality in ICT is championed and spear-headed by campaigning and advocacy organisations and scholars. This community organises its work through networks and other loosely structured formations. Conversely, ICT powerbrokers that have a vested interest in the status quo are much more likely to occupy staff positions of well-funded organisations and to use these positions to shape the agenda. There is much still to do to transform power-relations in the ICT sector.

The third and final factor is the absence of focus on ICT and development by the broad gender equality and women's rights movement (Marcelle, 2005). It is fair to say that the women's movement has not yet prioritised these issues. Matters to do with access and control of technology are still seen as the narrow concern of "techie" women, rather than as part of the overall struggle for peace, equality, and development. This situation arises partly because there are many candidates for priority attention and the international women's movement faces many challenges. However, in addition to the clamour of other sometimes seemingly more pressing issues, some features of the gender and ICT community also contribute to this state of affairs. With the gender and ICT movement, there has been a failure to define legitimate and priority advocacy issues. This lack of focus can be in part explained by the heterogeneity of women across the globe and varying perspectives on gender-equality and women's rights. Some advocates suggest that the intersectionality of class, race, sexuality, and religion is the appropriate lens for analysis and action, while others adopt a more pragmatic stance, and suggest use of the reform objectives of gender-mainstreaming. This lack of consensus also extends to strategies and tactics (Radloff et al., 2005). There has also been a tendency to draw quite sharp lines around the boundaries of the gender and ICT community and to be less than enthusiastic in building linkages with other gender advocacy communities—trade, labour relations, human-rights, economic reform, and peace—and learning from their successes and failures. This has to do, in my view, with a misdiagnosis of what is at stake. If the gender and ICT agenda ends with improving women's non-governmental organisations' (NGOs) ability to use ICT and to increasing women's access to ICT services and facilities, and does not tackle fundamental transformation of the ICT sector, it is unlikely to attract the interest of a wider community and to be considered to be relevant, legitimate, and important.

STRATEGIC RESPONSE

Feminism is what feminists practice; in building a global feminist movement that is relevant to all women, their development and human rights, we should ensure that there is more involvement in Information Society debates at the strategic level. It is possible to reclaim Information Society discourse and programmatic actions. To do so one would need to place feminist theory and its perspectives on globalisation, power-relations, and economic reform (Kabeer, 1994; Sen & Grown, 1987) at the centre of efforts to imagine and define strategies to develop a people-centred Information Society.

Feminist perspectives provide an insightful point of departure for the radical transformation of the ICT sector. It is essential that representatives of women's organisations and advocates of social change are included in strengthening a movement for change. Transformation of the ICT sector requires more than a concern about increasing access and usage or even about reducing disparities across countries.

Radical transformation requires an explicit analysis and critique of the sector reform policies that focus on liberalisation and privatisation (World Bank, 2002; WTO, 1998). On the basis of evidence, we should identify and analyse the effects of sector reform policies on the poor, women, and other marginalised groups. This analysis will show that ICT sector reform has brought advantages for modern, middle-class women employed in the formal sector, but has resulted in little change for her sisters and brothers in rural remote communities. The movement for change should be vocal and strategic in our demands. We should let the international community know that it is not enough to hope that in the long run, the market will solve these problems, because it is now clearly evident that macro and micro reforms have distributional effects, which are not equitable. Without intervention, they fall heaviest on the poor and the disenfranchised. We should not allow telecoms to continue to be a sector where there are marked distinctions between the haves and the have-nots.

A feminist analysis would also call for more careful analysis of the root causes of the digital divide. For the most part, the problem specification and the solutions proposed have focused on the supply side, rather than including demand factors and capacity building. The World Bank has led the way in a global consensus that suggests that once changes are made in market structure, and ownership changed from state to the private sector, all will be well. There has been considerable less effort on understanding the demand-side and proposing solutions to increase effective demand. A more integrated approach is needed. If this closer integration is achieved, the constraints on the demand-side—inability to pay—are better understood, and more appropriate responses can be developed (Mansell 2003; Mansell & When, 1998). It is obvious that the inability to pay for telecoms services, like so many other aspects of hardship in developing countries, can only be solved by integrated solutions which view human development as the first priority. A profitable telecoms company, which makes no contribution to improving quality of life, would not be an asset for the citizens of the developing world. We also need to pay greater attention to understanding and specifying the conditions under which ICT produces impact, including by improving the methodologies used in programme design, evaluation, and monitoring (Ravallion, 2001; Tongia, Subrahmanian & Arunachalam, 2005).

In a feminist perspective, the process of creating an information society would be considered to be a political process in which governments and other stakeholders invest a range of capital assets in expansion of the ICT sector and implementation of facilitating mechanisms associated with increasing use of ICTs. This is well understood in countries that undertake ICT policy as a consultative process involving all stakeholders, but not grasped by countries which embark on narrowly focused technical exercises (Marcelle, 2000b). Politics is never absent at any stage in the creation of an information society. In the early stages of expanding networks and infrastructure, national interest groups will be vying for licences, and global interests will compete for market entry. Once entrants are active in the market, the political process will turn to careful structuring of a balance between public policy interests and private returns as far as setting tariffs and universal service policy are concerned. Grasping this political dimension of the information society, carefully mapping patterns of power, influence and resistance to change are essential for the radical transformation of the ICT sector.

CONCLUSION

The question becomes not what ICT can do for women, but what can women and social change movements do for the ICT sector. The answer is clear—a gender perspective can improve the responsiveness and integration with the goals of human development, so bringing the ICT sector into the vanguard of development.

The challenges posed by the gender digital divide are far-reaching and fundamental. The ICT sector needs to build a community by integrating with social and development movements, including women's organisations, and by formulating plans for the sector which articulate with broad development goals. To do this, the sector needs to develop better conceptual tools and frameworks and to change its ways of working. A developmental agenda for the ICT sector should start from economic, social, and cultural realities.

By advocating an action orientated approach to taking on the gender digital divide issue, I argue that we will in the process tackle the myth of technology neutrality and engage with the power brokers in the ICT sector and reform power relations in the sector, including by occupying positions of power and influence and using those positions for the benefit of all people. If these efforts can be used as a means of broadening the gender and ICT community, and raising the profile of the relevance of Information Society debates within the broad gender and development community, there is a much improved chance of getting to a point where the gender differences in access to and control of ICT do not exist, and the ICT sector makes a more meaningful contribution to human development and peace.

KEY TERMS

Digital Divide: The digital divide is used to refer to the disparity in production, access, control and effective use of information and communication technologies. These disparities mirror economic, social and political global realities and arise because of unequal ddistribution of wealth, knowledge, power and opportunity across the globe. Within countries, the divide is manifested in significant divergence in access between economic classes, income levels, and racial groups and between urban and rural communities. There is also gender divide, in as far as poor women make up the majority of the urban and rural poor whose needs are not well understood and who are not able to afford access. Women are also disproportionately underrepresented in the production and research segments of the ICT sector.

Gender Blindness: Gender blindness results when socio-economic analysis and development programming does not take gender relations into account. It results in development policies and programmes not meeting the different needs of both women and men.

Gender Relations: Gender relations refer to the relationships between men and women, their access to resources, their activities, and the constraints they face relative to each other. Gender analysis provides information that recognizes that gender, and its interrelation with race, ethnicity, culture, class, age, disability, and/or other status, is important in understanding the different patterns of involvement, behaviour and activities that women and men have in society. An analysis of gender relations provides information on the differentiated conditions that woman and men face, and the resulting differences in the effects of policies and programmes.

Human Development: Human development is the process through which people enjoy greater opportunity and choice, particularly in terms of self-expression, self-actualisation, and access to information, knowledge and wisdom. Development takes place when human beings create conditions that enable them to lead long, healthy, creative lives and to enjoy a decent standard of living, with freedom, dignity, self-esteem and the respect of others, without compromising the ability of future generations and the natural environment.

Information and Communication Technologies (ICT): Information and communication technologies (ICT) consist of a complex and heterogeneous set of goods, applications and services used to produce, distribute, process and transform information. The ICT sector consists of segments as diverse as traditional telecommunications, television and radio broadcasting, computer hardware and software, computer services and electronic media (e.g., the Internet, electronic mail, electronic commerce and computer games), as well as the content of these media.

Information Society: Information society consists of the set of social, cultural, political, institutional and economic arrangements that facilitate rapid and widespread diffusion of information and communications technologies. Creation of an Information Society has the potential to provide significant benefits for, and have major impact on, the priority developmental goals in poor countries. However, it is not automatic and the public policy challenge facing developing countries is to shape the evolution of the information society to produce maximum benefit.

Intersectionality: Intersectionality holds that forms of oppression within a society, such as those based on race, gender, religion, sexuality, class, are interrelated rather than acting independently.

Sector Reform: Sector reform is a coordinated set of activities that result in significant changes in industry structure and practice in the ICT sector. The main pillars of sector reform as espoused by key architects such as the World Bank and the WTO include shifting operations away from governments; reducing monopoly power; separating and strengthening policy and regulatory functions; and introducing competition into markets and increasing private sector participation.

Social Construction of Technology: Technologies are shaped by social and political forces. As a result, moral values and interests are embedded in their design, production and use.

Technological Neutrality: Technological neutrality considers technologies to be a set of value-neutral tools, which can be used for better or worse. In this perspective, technology is considered often to be a coherent and comprehensive phenomenon, which acts as a force that determines culture and society.

Feminist Standpoint Theory

Clancy Ratliff
University of Minnesota, USA

INTRODUCTION

Feminist standpoint theory is an epistemological view set forth in the late 1970s and early 1980s described as "an engaged vision of the world opposed and superior to dominant ways of thinking" (Ruddick, 1995, p. 129). Its development was influenced by Marxist thought, specifically the idea that the worldview of the ruling class is compromised by its vested interest in upholding the current class structure. The proletariat, who has no such interest, is able to interpret reality from the standpoint of its own experience as well as that of the ruling class because the ruling class' ideas are widely inculcated and presented as "objective," advancing the view that social conditions are as they are, and they cannot be otherwise. This naturalization of the ruling class' ideas bolsters and affirms its privilege. The proletariat can inhabit both its own and the dominant perspectives, putting it at a more ideal epistemological and political vantage point.

Drawing upon this line of Marxist thought, feminist standpoint theory holds that women's social development and experiences are different from men's, and these experiences, taken with the sexual division of labor and women's portion of this work, including mothering, homemaking, and other emotional and relational labor such as nursing and social work (Hartsock 1983, 2004), enable women to interpret the material world from a unique standpoint. Implicit in this postulate is the assumption that men are the ruling class, and the dominant worldview is masculine. The feminist standpoint, its proponents argued, could be used as a methodology to make more accurate, holistic, and socially responsible knowledge. At the heart of feminist standpoint theory, Braidotti (2003) argues, is the emphasis on the difference between men and women and the focus on women's experiences as a means to knowledge production. Belenky, Clinchy, Goldberger, and Tarule (1986), Chodorow (1978), and Gilligan (1982) extended the feminist standpoint project by studying women's epistemological, psychological, and moral development, respectively, and the theories that emerged from their studies in particular have had considerable influence on early work in gender and information technology.

BACKGROUND

In the late 1970s and the 1980s, feminist standpoint theorists in psychology and education worked to correct what they perceived as male bias in theories of development and, in general, the "dominant intellectual ethos" of the time (Belenky et al., 1986, p. ix). In response to influential theorists such as Freud and Piaget, these researchers built theory that was grounded in women's experience. Chodorow (1978) theorizes women's development from a psychological perspective. She describes the "reproduction of mothering" as a built-in facet of girls' and women's personalities; because girls are mothered by women, they see their mothers as role models and, in turn, themselves desire to mother. Chodorow argues that the reproduction of mothering is a social psychological process that helps to keep gender hierarchy in place as long as women are the ones expected to care for children. That children are mothered by women has strong implications for the personality and development of girls. Girls take a much longer time to separate from the mother than do boys and therefore see themselves as more continuous with their mothers. Chodorow points out that due to the continuity and identification with their mothers,

> *girls emerge from [childhood] with a basis for "empathy" built into their primary definition of self in a way that boys do not. Girls emerge with a stronger basis for experiencing another's needs or feelings as one's own (or of thinking that one is so experiencing another's needs and feelings).* (p. 167)

Because a girl is mothered by a woman who anticipated her needs as an infant and child, she in turn learns to anticipate and meet others' needs.

Gilligan (1982) explores women's development with attention to ethics and morality. Based on her interviews with children and women, Gilligan argues that the tacit prescription that women should care for others and prioritize others' needs and desires before their own emphasizes "the concepts of responsibility and care in women's construction of the moral domain" and a "close tie in women's thinking between conceptions of the self and of morality" (p. 105). Gilligan theorizes that if women think of ethics and morals in terms of rights, or what they are themselves entitled to, they can balance ethics and morality between the needs of the self and the needs of others, going from "the paralyzing injunction not to hurt others to an injunction to act responsively toward self and others and thus to sustain connection" (p. 149). She argues that if women do not see moral decisions in terms of what they are entitled to, the problem she identifies will continue. First, women will, when making moral decisions, continue to sacrifice their own needs and wants for their perceived obligations and responsibilities, and continue to see their actions primarily in terms of how they will affect others. Second, masculine bias will continue in theories of development if researchers fail to take into account women's perspectives and experiences, or women's "voice," resulting in theories of human experience that lack the appropriate complexity (Gilligan, 1982, pp. 173-174).

Belenky et al. (1986), after noticing that "women often feel alienated in academic settings and experience 'formal' education as either peripheral or irrelevant to their central interests and development" (p. 4), studied the way women acquire knowledge and experience knowing. They found a continuum in women's epistemological development that goes from silence, a metaphor taken from Olsen's (1978) study of the history of women writers, which they define as "an extreme in denial of self and in dependence on external authority for direction" (p. 24); to received knowledge, or listening to authorities and accepting their explanations as definitive; to subjective knowledge, in which women start to develop an inner voice and gain some authority as knowers. The next category is procedural knowledge, which they divide into separate knowing and connected knowing. Separate knowers have "procedures for making meaning [that] are strictly impersonal. Feelings and personal beliefs are rigorously excluded" (p. 109). Connected knowers, the most highly developed knowers in their taxonomy, see themselves as authoritative and as having a personal stake in knowledge. They value the personal and emotional and bring them to what they seek to understand. Connected knowers understand that they play a part in shaping knowledge. Belenky et al. argue that a pedagogical approach geared toward collaborative learning and experiential knowledge, an approach that stresses "connection over separation, understanding and acceptance over assessment, and collaboration over debate" (p. 229), is best suited to women's learning styles, and that educators can and should include women's experiences and learning styles in pedagogical theory, curriculum design, and teaching practice.

FEMINIST STANDPOINT THEORY AND COMPUTER CULTURE

Wajcman (1991) claims that "technology is more than a set of physical objects or artefacts. It also fundamentally embodies a culture or set of social relations made up of certain sorts of knowledge, beliefs, desires, and practices" (p. 149). Much of the feminist work in information technology has been concerned with technology as culture, or, as Lay (1996) terms it, computer culture. Feminist researchers have synthesized the insights offered by feminist standpoint theorists, especially those reviewed above, with men's and women's attitudes toward computing and experiences with information technology in educational, domestic, and occupational settings. They described values and practices often associated with computer culture—competition, individualism, and hierarchy—as masculine, and they criticized the exclusion of the values of connection, relationality, and collaboration found to be common among women. The association of computing with masculinity goes back to childhood for many women, when girls often have more responsibilities at home, and "girls' extracurricular activities are generally much more restricted than boys'" (Wajcman, p. 154). Girls are not encouraged to play computer games, participate in computer camps, and engage with the computer as much as boys are (Wajcman, 1991). Moreover, most computer games are designed using the masculine values of hierarchy and competition. Computer science instructors, for the most part, have not used feminist theories of women's development in their course design and pedagogy and have, perhaps unwittingly, perpetuated gender stereotypes surrounding boys, girls, math, and science, alienating girls (Wajcman). This early experience with computers in the home and at school is crucial because it establishes a pattern that tends to continue into adulthood; to wit, historically, and even now, men outnumber women in technical professions.

IT research influenced by feminist standpoint theory offers a genealogy of how computer culture is rooted in masculine epistemological tradition. Lay (1993) points out the "remnants of scientific positivism" in computer culture (especially in the development of hardware and software) as well as the tendency to divide the world into dichotomies that are "either objective or subjective, allied with nature or culture, governed by emotions or rational thinking, these dichotomies privilege what society labels as masculinity" (p. 222; see also Wajcman, 1991). Selfe and Selfe (1996) add that computer production and networking has its origins in the military, with the motive of making military communication more efficient in times of war. Dominant knowledge, which feminist standpoint theorists would argue is masculine, structures how knowledge about computers gets communicated, and one can see evidence of this gendering in the selection of interface metaphors, including the violent masculine metaphors *kill* and *abort*. Gerrard (1999) cites Selfe and Selfe's challenge to imagine a computer with the interface metaphor of *kitchen* or *workbench* rather than *desktop*, each of which would gender or class the computer differently. However, while the language that is used to communicate technical knowledge reveals much about the culture in which tools are embedded, the relationship between language and practice is not a transparent and deterministic one (Wajcman). Education is an important context to study, which feminist researchers of information technology have done using standpoint theory.

Lay (1996) identifies several differences between men and women's learning styles: She critiques top-down programming for its hierarchical, masculine thought style and points to Turkle and Papert's study of computer programmers, noting that most computer learners classified as "bricoleurs" are women. Bricoleurs "tend to anthropomorphize the computer and seek transparency, closeness, and visual manipulation when learning and using the computer" (pp. 68-69). Instead of top-down programming in which the programmers write modules of code conforming to the designer's plan, bricoleurs prefer moving the modules around and rearranging them until the program is completed. Turkle (1988) describes this kind of interaction as "a relational encounter," "an artistic, almost tactile style of identification with computational objects, a desire to 'play with them' as though they were physical objects in a collage" (p. 50). Men are more interested in the computer itself, whereas women are more interested in the computer as a tool or means to completing a task. In the study of computing, women sometimes feel alienated; Turkle argues that they see not only the computer itself, but all its cultural associations. She writes:

> *[w]hen women look at the programming virtuosos around them, they, unlike men, see themselves as cut off from a valued learning style. Male risk taking is equated with computational "intuition." In educational and professional environments where hackers present an image of "the best," women often see themselves as lesser. They see themselves as "just users," as competent but not really creative.* (p. 49)

Lay (1996) recommends that computer documentation textbooks accommodate diverse learning styles, including those commonly associated with women, which value relationships, collaboration, and nonhierarchical programming methods.

Studies in computer-mediated communication have also drawn heavily upon feminist standpoint theory, arguing that differences sometimes exist in the ways men and women communicate in networked environments. Herring (1996), who admittedly does not use standpoint theory in her work, has gestured toward two types: the informative male and the interactive female. The informative male often states his opinions as fact, makes clear assertions, uses fewer emoticons, and takes a more critical stance toward information introduced into the discussion. In contrast, the interactive female couches her opinions in leading questions, makes attenuated assertions, hedges (uses *perhaps*, *maybe*, *it seems*), uses more emoticons, has a more personal or interpersonal style, and is more interested in exchanging information than criticizing it. Herring qualifies these types, however, by noting that men and women use both communicative styles depending on the situation, and her research has shown that, in a group discussion, the minority gender conforms to the majority gender's norms even if the minority gender is male. LeCourt (1999, pp. 163-164) concedes that an "invitational" style, when used by a woman, could be associated with "'women's' ways of knowing," but warns that this association "provides an opportunity for [women's] discourse to be positioned as 'lesser.'" Feminist researchers in rhetoric and composition have acknowledged this inclination to hierarchize differences but have still taken feminist standpoint theory seriously in their studies of writing and discussion in electronic environments. Grigar (1999) found that her female students used e-mail to reach out to other students and to her, their teacher. Gerrard (1999) and Grigar argue that teachers can use e-mail to forge caring, nurturing relationships with students. Gerrard (pp. 387-388) also argues that using hypertextual forms of writing, which can be chaotic, nonlinear, and sometimes collaborative, can provide a welcome contrast to "the linear, argumentative essay, which rhetorical theorists have argued is a 'masculine' form—hierarchical, contentious, and competitive." However fraught focusing on differences between men and women may be, many rhetoricians of technology have found standpoint theory useful in forming pedagogical theories. Lay (1996) argues that Belenky et al.'s (1986), Chodorow's (1978), and Gilligan's (1982) theories have value because they are valid for many men and many women.

FUTURE TRENDS

In recent years, feminist standpoint theory has fallen out of favor as a methodological tool in feminist research due in part to the influence of postmodernist thought, which eschews essentialist, reductive, dualistic, deterministic thinking, favoring instead multiplicity, complexity, and contextualization. Feminist standpoint theorists have stated explicitly that they do not mean to propound a view of biological determinism. Rather, they argue, any differences that may exist are socially constructed and perpetuated, and therefore are able to be overcome with more egalitarian social practices. Furthermore, feminist standpoint theorists emphasized that differences do not have to be constituted in a superior-inferior dichotomy.

However, standpoint theory has still been criticized as essentialist. Critics of standpoint theory have argued that it tends to overgeneralize about men's and women's behavior, and that focusing on cognitive differences minimizes the importance of social context. Wajcman (1991), for example, highlights the fact that technology as culture has been closely associated with war machines and weapons, usually gendered masculine, but that women have served in combat and provided much help to war efforts. Men, on the other hand, have historically been more active than women in organizing mass war-protest efforts. Critics of standpoint theory also argue that no one has epistemological privilege—not even women—and that dichotomous, oppositional thinking ends up reifying gender hierarchies rather than dismantling them. Additionally, standpoint theory tends to generalize about women as one group and does not account for differences among women. Hekman (1997, p. 341) writes, "[p]articularly among younger feminist theorists, feminist standpoint theory is frequently regarded as a quaint relic of feminism's less sophisticated past." While feminist standpoint theory was influential in early studies of gender and information technology, it is unlikely that it will continue to be; most feminist researchers view gender as performative. In future research, if standpoint theory is used at all, it will be used in a carefully qualified, historicized, tactical manner, and not likely as a primary theoretical framework.

CONCLUSION

Feminist standpoint theory is rarely used in current research on gender and information technology, but it is a significant part of the intellectual history of this field. Markham (2003) says that Internet researchers:

need to place our research in history; ahistoricity is a problem. Go to other researchers' work even if you're working with a new technology—other researchers have already thought through most epistemological and theoretical problems. There's a tendency in Internet research to reinvent the wheel, or invent a method to use.

Standpoint theory has historical value not only because it is a large part of the foundation of gender and information technology, but also because it produced windfalls for gender theory in general: It "started the conversation about situated knowledges" (Hekman, 1997, p. 344), and it helped to bring issues of race, class, ability, and sexuality into feminism.

KEY TERMS

Biological Determinism: The idea that differences between men and women are innate, biological, and therefore insurmountable.

Computer Culture: The cultural context in which computing practices emerged and continue to take place.

Computer-Mediated Communication: Communication that takes place in networked, electronic environments, sometimes on the World Wide Web, but not necessarily.

Essentialism: The belief that all members of a group share common attributes. For gender, men might be seen as naturally stronger, more aggressive, logical, and independent, women as weaker, more passive, emotional, and more dependent on social relationships.

Performativity: The idea that gender is a learned, daily act grounded in social norms of heterosexuality, femininity, and masculinity rather than biological sex. Taken by Judith Butler from the work of linguists J. L. Austin and John Searle.

Positivism: The epistemological view that argues that the only valid knowledge is that which applies formal rules of logic to empirically observable facts in material reality.

Situated Knowledges: Refers to the argument that knowledge is produced in social contexts and from particular social locations that influence how the knowledge is shaped.

Five Perspectives on Women and Men in the IT Workforce

Mark Wardell

Steve Sawyer
The Pennsylvania State University, USA

Jessica Mitory
The Pennsylvania State University, USA

Sara Reagor
The Pennsylvania State University, USA

INTRODUCTION

The opportunities in a variety of information technology (IT) occupations, such as software engineer, systems analyst and consultant, combined with increased employer interest (and need) for workers whose essential skill is knowledge and not brawn, intimate that IT is a "level playing field." That is, simply possessing IT-related skills might mean that a worker's gender would not be a discriminating characteristic for job-related outcomes in IT work. The perception of high-paying and gender-neutral work should encourage women to enter IT fields. This should be magnified by the increases in resources (public and private) designed to enable women to acquire IT-related skills. For example, early introduction programs, such as the Girl Scout's STEM program, encourage entry into IT work through newsletters, career information and mentoring opportunities for young girls in the subjects of science, technology, engineering, and mathematics (Girl Scouts of America, 2004).

BACKGROUND

With STEM and other early intervention educational programs, women should be participating in advanced math and science courses on par with men (Leventman, Campbell, Cullinane, & Perry, 2004). Increased access to educational resources in mathematics and science should prepare women to participate in equitable proportions as their male counterparts in IT. Nevertheless, evidence shows that 33%-41% of the entire United States (U.S.) IT workforce are women, and only 25%-30% of the professionally trained IT workforce (Information Technology Association of America 2001)[1]. This suggests that women are underrepresented in IT, regardless of increasing availability of high-paying positions in IT fields and various supportive factors in the social environment. Moreover, given the number of people who enter the IT workforce with post-secondary degrees in English and history, the underrepresentation of women in IT work may not be explained solely by the declining rates of women obtaining bachelor's degrees in computer science and related programs (National Science Foundation, 1996; Eliassen, 1997).

One conclusion from these observations would be that gender seems to make a difference in employment and job opportunities for the professional IT workforce. We agree, hypothesizing there are interactions among institutional characteristics associated with education, families, industrial markets and workplace organizations, and that these frame patterns of work-related outcomes for the professional IT workforce. The pattern of outcomes, though, tends to be different for women and men. Before elaborating on our model, we first review other theoretical viewpoints, including human capital, essential differences, social constructionist and techno-feminist, which are often referenced when discussing work-related outcomes for workers in general.

Human Capital Perspective

The human capital perspective is premised on a cost-benefit analysis for investing in skill enhancement (Becker, 1962). For example, if the anticipated returns from higher education or firm-specific training are greater than the costs, a person theoretically would be likely to invest in additional education or training. The benefits from skill enhancement could include higher earnings, promotions, increased job autonomy and higher job satisfaction. The human capital perspective explicitly suggests that work-related outcomes depend largely on IT workers' quantity and quality of human capital investment. Implicitly, the human capital perspective assumes that neither gender nor technology *per se* necessarily influence job selection or work-related outcomes.

Essentialist Perspective

In the essentialist's view, men and women have innate differences that lead to gendered outcomes. Gendered responses to stress, for example, are believed to reflect those differences between males and females. Males respond to stress through aggressive actions, and this is considered ideal for leadership positions in the workplace. Females, however, tend to befriend and pacify others in times of stress (Barnett & Rivers, 2004). Males are thought to emphasize systemizing, analyzing, exploring and governing, whereas females emphasize empathizing and nurturing others. Thus, occupational selection might find women seeking to work in settings that do not violate their feminine nature, whereas men might find that high-level organizational positions fit with their intellect and logic (Barnett & Rivers, 2004). An essentialist view suggests that a feminine nature would necessarily limit women's employment opportunities in various IT occupational fields, such as network and systems analysis, computer engineering or database administration. As with the human capital perspective, technology *per se* does not influence either job selection or work-related outcomes.

Social Constructionist Perspective

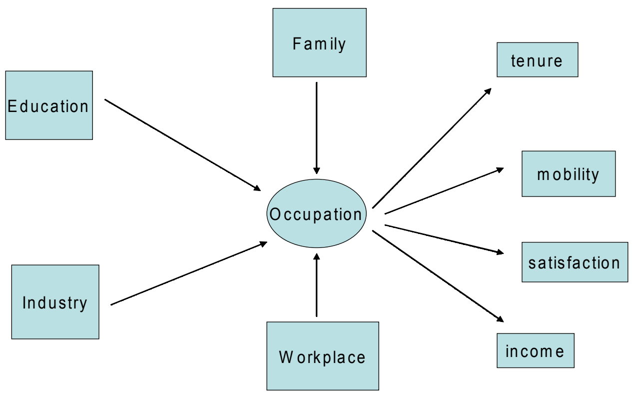
According to the social constructionist perspective, men and women are socialized by distinct social influences that ultimately lead to more valuable work-related outcomes for men than women. From this perspective, men are taught at a young age to value achievement and competition, whereas women are taught to value affiliation and social relationships (Abu-Saad & Isralowitz, 1997). Through this social process, women learn to value attachment to family, whereas men learn to value attachment to the workplace. Men are socialized to have an instrumental orientation toward work, while women are socialized to have a communal orientation that emphasizes harmony, connectedness and concern for others (Mason, 1994). As a result, women might be less interested than men in the more technical occupations (Barnett & Rivers, 2004). Since professional technical occupations are often associated with greater rewards in terms of pay, prestige and career advancement, men might have considerably more opportunities to secure better work-related outcomes than women in IT-related fields. Social constructionists also view technology as a gender-neutral phenomenon.

Techno-Feminist Perspective

According to the techno-feminist perspective, technology historically has been created and designed largely by men for specific masculine projects. In this sense, technology is viewed as an integral part of the masculine identity, whereas femininity is at minimum incompatible with most technologies (Wajcman, 1991). This gendering leads to different social relations at work and different work-related outcomes for men and women (Wajcman, 1991, 2004).

For women to successfully engage technology, they must abandon their femininity to some degree to better understand technology's masculine language and implementation. From this perspective, the implementation of technologies originates with powerful men, while technologies also convey power to those who implement them. Without specific knowledge on how to best make use of IT, for example, women cannot potentially possess power in the workplace.

Figure 1. Institutional model of IT work



Men, on the other hand, gain power over women by their acquisition of technical knowledge and competence. In this context, women might lose their desire to enter or actively participate in a technical workforce because of a masculine dominance and forgo the opportunity to acquire skills necessary to thrive in a technology field. One consequence of this "decision" could well be employment in low-skilled, low-wage occupations.

In sum, these four perspectives tend to overlook the significance of the various organizational domains, or institutions, that structure personal experiences in the workplace. They also tend to see the relationship between gender and technology as being relatively unproblematic. Importantly, we know some women do enter technology fields and are very successful, suggesting the relationship between gender and technology is problematic. Thus, we propose an institutional perspective that includes the conception of an occupational career as a life-long process influenced by key social institutions.

FUTURE TRENDS: THE INSTITUTIONAL VIEW

We advance here a fifth perspective on the relationships between gender and IT work: the institutional view. The institutional view begins with the notion that "… the responsibility for the behaviors people engage in at work and their fate inside organizations …" resides largely in the structures of the institutions surrounding them (Kanter, 1977, p. 10). Moreover, throughout their life course, men and women workers experience occupational and personal changes related to these institutions that directly reshape their career paths. From this perspective, IT is a socially constructed phenomenon that historically has reflected a masculine gender in the U.S., while simultaneously enhancing the power of certain segments of society. Questions abound today whether the role of IT in the informational global economy will lead to a more even distribution of power.[2]

As we show in Figure 1, the life course of an IT worker is shaped by institutional contexts in which they live and work, including how their IT skills will be used, enhanced and rewarded, and how they will view their opportunities and appraise their priorities with the passing of time (Kanter, 1977; Krecker, 1994; Kalleberg & Moody, 1996). The educational institutions, industrial markets, workplace organizations and families are seen as influencing critical life-course junctures and work-related outcomes.

Educational Institution

The type of educational institution where people earn post-secondary degrees has possibly significant effects on their first jobs (Feagin & Feagin, 1986; Von Hellens, Nielsen, & Trauth, 2001). Salzman (2000) reports that human resource managers hiring IT workers do, in fact, consider the type of degree as well as ranking of the educational institution during the selection process. Indeed, opportunities for certain advanced undergraduate courses, internships and career mentoring in IT throughout an individual's college experience can lead to differences in opportunities for the first job.

Barnett and Rivers (2004) argue that persistent stereotypes within educational institutions influence educational outcomes. Throughout their educational experience, women are discouraged from taking math and science courses, since these subjects are believed to be inherently masculine. But, gendered educational experiences lead to gendered occupational outcomes by discouraging women from careers in engineering and IT,while encouraging them to pursue careers in nursing or teaching that complement their feminine stereotype as nurturers.

Industrial Markets

The type of industry where IT work is done can influence the orientation and expectations of workers at critical life-course junctures. Industrial markets have different product cycles and levels of competition, plus technological work varies by the type of industrial market where the IT work is performed. IT workers most commonly can be found in three major industrial markets: vendor, consulting and application industries (National Research Council, 2001). Of the three, the application industry represents the most highly dense concentration of IT workers.

The vendor industry includes a few large, and many small, companies that create, develop and market both custom and packaged software. It is further characterized by frequent spin-offs and mergers, where companies tend to buy other companies for their patented technology and skilled workforce. This industry is characterized by high levels of product innovation and short product cycles, making the vendor market prone to high levels of competition. Part of the competitiveness in this industry relates to the vendors' abilities to respond to changes in customer needs and part relates to the low start-up costs. In addition, these organizations tend to be young and lack the human resource experiences of more seasoned employers.

Employees in the vendor industry tend to be highly educated, holding degrees beyond the bachelor's level. They work comparatively long hours to attain competitive salaries. These long work hours and lack of employer experience with human resources suggest that family-friendly policies probably are not yet well developed or widely practiced within this industry. We would expect women in this situation to have some difficulty juggling conflicting priorities between work and family, since they are more likely than men to seek ways to customize their work schedules by going from full-time to part-time employment, sharing jobs with other women in similar positions or subcontracting (Meiksins & Whalley, 2002). The industrial characteristics of vendors, therefore, tend to present men with more opportunities for better work-related outcomes than women. Perhaps this accounts for the comparatively few professional IT women working in the vendor industry.

Unlike the vendor industry, the consulting industry consists of highly diversified companies that analyze, recommend and assist end users of IT regarding the most efficient and effective hardware/software vis-à-vis a business strategy. Companies range from those that specialize solely in IT to those that consult on a range of services, including marketing, accounting, finance and IT systems. Due to the breadth of services provided within this industry, companies range in size from single-individual consultants to large multi-national firms and range in maturity with human resource practices and policies. Female participation in the consulting industry is likely to range in correlation with human resource policies.

In the IT consulting industry, travel is often required as part of the workload. As women struggle to juggle work and family commitments, they often avoid employment opportunities that require extensive time away from home (Meiksins & Whalley, 2002). Consequently, we expect this reasoning will account for some of the under representation of women in the IT consulting industry.

The application industry is comprised mostly of mature companies that use packaged software adapted to a specific service or product. In this situation, the IT is not the end product of the companies, but it is fashioned to enhance delivery of the final product. The majority of IT professionals working in the application settings work in banking and finance, insurance, health care and, increasingly, material applications. Compared to the vendor industry, the application industry tends to be relatively stable. The companies tend to employ large numbers of people, and therefore, they are obligated to obey federal employment laws and regulations. As a result, companies within the application industry tend to have established human resource practices and policies, which often include family-friendly policies. Accordingly, many professional IT women might well seek employment in the application industry due to these "female-friendly" policies.

Organization of the Workplace

The organization of the workplace reflects the division of labor among workers and how their work efforts are coordinated towards common objectives. Accordingly, the distribution of formal organizational power, work schedules, relations among co-workers and between workers and management, training opportunities and compensation systems potentially can impact differences between men's and women's work-related outcomes.

Most large or well-established organizations, such as those in the IT application industry, are characterized by a hierarchy of promotional paths that define the skill sets required to hold a position, and the levels of skills needed for advancement. These paths represent levels of authority as well as internal labor markets. As workers demonstrate levels of skill and responsibility critical to the central objectives of the organization, they advance upward on the promotional ladder. Men, however, hold more than half of the managerial positions in the U.S. (Tomaskovic-Devey, Knoke, & Spaeth, 1996). In fact, the gender of a supervisor makes a significant difference in advancement opportunities of women, their personnel evaluations and initial earnings (Reskin & McBrier, 2000). Hence, a gendered pattern emerges where typically masculine jobs offer higher monetary rewards and embody more power inside the organization than typical feminine jobs within the same industrial sector (Kanter, 1977; Cockburn, 1991). The result is gender segregation in the workplace.

Because organizations in the vendor industry must be flexible and responsive to customers' needs, the organizational structure itself must be more streamlined where responsibility is distributed, rather than centralized throughout the organization. Often referred to as high-performance work systems, these workplaces differ from the more traditional bureaucratic workplaces by including flexible technologies, team-centered cooperative work arrangements, classification of workers by skill rather than by rigid job titles and knowledge sharing (Godard, 2001; Appelbaum, Bailey, & Berg, 2000; Rogers, 2001).

Compensation systems, too, reflect the organization of work. In the high-performance vendor industry, for example, compensation is based on performance rather than time spent at work. Personal wages in this situation approach the higher end of the range for IT workers. The compensation system in the IT application industry is more traditionally based on standard forms of evaluation, such as grade level and hours worked. Because it is more common for men to be at a higher level than women within an IT application environment, men tend to be compensated significantly more than women. Hence, women seeking careers in professional IT-related fields would find more opportunities and better rewards in the vendor and consulting industries, but they are likely to find fewer family-friendly employers in those industries.

Familial Structures

As an institution, the family has extensive influence shaping the career aspirations and work orientations of individuals. Characteristics of the immediate family are known to influence job satisfaction, willingness and ability to work extended hours or travel for business purposes, and ability to cope with job-related stress (Carlson & Perrewe, 1999; Thomas & Ganster, 1995). Key family characteristics include marital status, children under the age of 18, employment status and occupation of partner and the status of health among family members. Importantly, men and women differ significantly in terms of responsibility for integrating familial and work commitments (Moen, 2003; Presser, 2003).

They also differ in terms of their personal adjustments to integrating work and family. Men often experience work and family dissonance when they work longer hours than their spouses, are involved in an unstable marriage or perceive an inequitable distribution of household labor. Women, on the other hand, report work/family imbalance when they are in an unhappy marriage or when young children are present in the home (Hochschild, 1997; Presser, 2003).

Since occupational pathways overlap with family trajectories for men and women throughout their lifetimes, marital and parental statuses are often robust predictors of employment and earnings for women and men. Women are considerably more likely than men to make employment sacrifices, such as choosing to have a job as opposed to a career. These sacrifices have consequences for women's work hours, advancements and incomes. Consequently, career development and work-related outcomes are more directly influenced by family status for women than for men, though some professional IT men have opted for a reduced work schedule in order to better attend family responsibilities (Meiksins & Whalley, 2002). For some observers of the IT workforce and the information economy in general, computing is seen as enabling a more accommodating work schedule for family responsibilities (Rifkin, 1995), but the evidence is not uniformly conclusive (Wajcman, 2004).

CONCLUSION

The institutional perspective offers a more comprehensive view of women's and men's career paths in IT when compared to human capital, essentialist differences, social constructionist and techno-feminist conceptions. All but the human capital perspective suggest women in IT face an unlevel playing field independent of intent, skill or ambition. In doing so, however, the relationships among career intent, skill, ambition and gender are not made theoretically problematic in relation to IT work and the contexts in which that work occurs. In contrast, the institutional perspective acknowledges the problematic nature of one's life course as it unfolds over time in relation to contextual changes, thereby accounting for how this process shapes differences in career development for men and women. Effectively, the institutional perspective concentrates attention on the interactions of various institutional influences that produce gendered work-related outcomes.

KEY TERMS

Essentialist Perspective: Men and women have innate differences that lead to gendered outcomes. Thus, men's and women's take-up and uses of computing differ based on biological differences.

Human Capital Perspective: There is a cost-benefit analysis for investing in skill enhancement: The more skills a person has, the more valuable they are to employers. Competence is the singular measure of value.

Institutional Perspective: People's actions are guided and changed by social contexts. The family, industrial markets, work organization and education are among the basic institutions.

Life Course: The pattern of interactions people experience within various institutional contexts are social actions. Life courses are temporal, path dependent and marked by events.

Social Constructionist Perspective: Men and women are socialized by distinct social influences that ultimately lead to more valuable work-related outcomes for men than women. Thus, men and women learn through socialization to act differently towards IT.

STEM: Science, technology, engineering and mathematics. Educational degrees seen by the U.S. Department of Education and the National Science

Foundation as those that prepare scientists and engineers.

Techno-Feminist Perspective: IT historically has been a masculine project. For women to successfully engage in IT work, they must abandon some degree of their femininity to better understand IT's masculine language and implementation.

ENDNOTES

[1] Evidence makes clear that women generally obtain lower levels of work-related outcomes because of their "second-shift" responsibilities as primary child-bearers and care takers. To be sure, numerous employers across the U.S. IT landscape have acknowledged the value of practices that enable workers, especially women, to balance responsibilities between family and work, but barriers for the utilization of relevant polices too frequently limit the opportunities to take advantage of the practices (Frankel, 1998; Thompson et al., 1999).

[2] Central to these questions remains a concern about who controls and has access to the advances in technology. While masculinity has been historically represented in technologies more than femininity, certain groups of women have gained influence and prestige by the relationships with men who control the advancement and implementation of new technologies.

Fostering Technology Interest Among High School Girls

Donna M. Grant
DePaul University, USA

Theresa A. Steinbach
DePaul University, USA

INTRODUCTION

This article describes a pilot program that uses a holistic approach to address the multitude of barriers girls face when considering a career in the information technology (IT) field. Girls with Engineering Mindz (GEMz) is a highly structured technology program developed to encourage female high school students to embrace technology while strengthening their academic, personal, and social development. GEMz is not just a program for girls to develop technical skills. The premise of the GEMz program is to attract and maintain its participants by developing multiple components of the "whole" person. The GEMz program was designed to attract its participants to the IT industry through a three-prong strategy: develop technical skills in a societal framework, enhance basic life skills, and promote positive self-images. The name GEMz was selected to promote enthusiasm and collaboration among program participants. Teams are given the names of precious gems, (e.g., Diamonds, Rubies, etc.) to symbolize their positive self-worth as valuable contributors to both technology and their communities.

BACKGROUND

During the past two decades, numerous researchers have reported on the dissipating ratio and the shrinking pipeline of women in IT (Camp, 1997; Frenkel, 1990; O'Lander, 1996). According to the National Center for Education Statistics, in the 1983-1984 academic years, 37.1% of the bachelor degrees in IT were awarded to women. Unfortunately, 19 years later, for the 2002-2003 academic years, women were only awarded 27.0% of the bachelor degrees in IT, a 10.1% decrease.

The under-representation of women in IT is a downward, spiraling cycle, a self-perpetuating phenomenon. Consider the research literature and develop a scenario of a female high school student who is an excellent problem-solver, a logical thinker, and someone who enjoys working with both computers and people. The student is considering her aspirations to attend college and contemplating her major. According to Teague (2000), many girls do not view computer science as a viable career option. Rowell et al. (2003) found "… enjoyment and interest have been shown to be a major reason students select a career … " (p. 54). They reported that males were 17.0% more likely to have an interest in computer programming. Weinberger's (2004) research indicated that many girls did not choose IT as a major because they did not think the courses would be interesting. Girls may have the misconception that the primary career in IT is a programmer who sits alone in a room hacking at a computer all day with little opportunity to interface with other people (Beyer, Rynes, & Haller, 2004; Margolis & Fisher, 2002). Furthermore, during their formative years, girls tend to not have the same "magnetic attraction" to computers that some of their male counterparts do (Margolis & Fisher, 2002). Girls usually do not consider themselves "hackers" or "computer geeks," and due to social gender stereotyping, the computer has been labeled as a "boy's activity" (Kiesler, Sproull, & Eccles, 1985; Margolis & Fisher, 2002;

Moorman & Johnson, 2003; Pearl et al., 1990; Shashaani, 1994). Girls who are interested in the IT field are so outnumbered that there is an intense "sense of isolation" (Frenkel, 1990). As if this sense of isolation were not enough, the boy's magnetic attraction to computers and societal biases help to perpetuate the expectation of students, parents, and educators that "boys and men, not girls and women will excel in and enjoy computing" (Margolis & Fisher, 2002, p. 16). Consequently, the current computer culture is alienating and uncomfortable for girls and women (Frenkel, 1990; Kiesler et al., 1985; Pearl et al., 1990).

How can girls become more knowledgeable and comfortable with the IT industry? Unfortunately, Jepson & Perl (2002) noted, "school counselors typically have very little basic information on the IT industry…" (p. 37). Furthermore, one of the most cited research issues regarding understanding the IT industry is that while girls usually have first-hand knowledge of female doctors, lawyers, and teachers, girls do not have sufficient female IT mentors and role models (Cohoon, 2002; Klawe & Leveson, 1995; Moorman & Johnson, 2003; Spertus, 1991; Townsend, 2002). Additionally, researchers have reported that some women feel significantly less confident than men in their computer ability (Beyer et al., 2004; Margolis & Fisher, 2002; Shashaani, 1994; Teague, 2002). Considering the possibility of the cumulative effect of these interest barriers, it is no wonder that girls lack a career interest in the IT field. The female high school student who is contemplating a major decides not to pursue a career in IT and the cycle continues …

PROGRAM MODEL

Girls with Engineering Mindz (GEMz) is a highly structured technology program developed to foster IT interest by developing numerous components of the whole person. The GEMz program is based on a holistic approach, designed to attract young women to the IT industry by combining strategies suggested by previous research. These strategies include: foster overall computer usage (Shashaani, 1994); develop technical skills in a societal framework (Margolis & Fisher, 2002); dispel the geek misperception (Beyer et al., 2004; Margolis & Fisher, 2002; Pearl et al., 1990); build self-confidence (Beyer et al., 2004; Teague, 2002); and expose GEMz participants to female IT role models (Cohoon, 2002; Klawe & Leveson, 1995; Moorman & Johnson, 2003; Spertus, 1991; Townsend, 2002).

The primary goal of the program is to inspire female students to use, experiment with, and feel comfortable with computers. GEMz is designed to portray the IT industry as both a human and a technical discipline. The focus is to encourage female high school students to improve their technical skills through utilizing computer technology for a purpose: the betterment of their communities and society as a whole. GEMz supports the ideology that numerous activities in the IT industry involve working on teams and not just sitting alone in a room hacking at a computer all day. The majority of IT jobs include a combination of individual and team activities. Therefore, it is essential for GEMz participants to enhance their skills through personal contribution and team collaboration. This concept of team is expanded to community, as GEMz participants broaden their sense of social responsibility through involvement in a community service activity. Female IT role models are utilized to help support and encourage young women and serve as living examples of successful women in the IT industry. Interacting and obtaining guidance from successful role models helps enhance the self-confidence of GEMz participants. It also provides positive evidence and imagery to enable them to recognize and visualize their full potential.

PROGRAM IMPLEMENTATION

The GEMz program implementation structure employs a three-tiered, holistic approach to attract high school girls to the IT industry. The tiers are: Tier I—Develop Technical Skills in a Societal Framework; Tier II—Enhance Basic Life skills; Tier III—Promote Positive Self-image and Encourage Social Interaction. All activities in the GEMz technology program seek to provide young women with a well-rounded exposure to IT, community, team-building, and self-development. The following sections describe the specific tactics executed to implement the three-tiered, holistic approach.

Tier I: Develop Technical Skills in a Societal Framework

The GEMz 2002 program was titled "Promoting Community Organizations." Teams created fictitious community service organizations, established missions, budgets, and structures, then designed and developed Web sites to promote their organizations. Agency services ranged from extreme sport outings for inner city youth to teen pregnancy prevention programs. A female professor from DePaul University's School of Computer Science, Telecommunications and Information Systems (CTI) and a female CTI graduate student taught FrontPage 2000 as the Web site development tool. Teams were also taught SWiSH 2.0, a Flash animation software package. The teams accessed various online sources to create their banners and logos. In addition, they used JavaScript forms to develop an interactive portion for their Web sites.

The GEMz 2003 program was titled "Chicago Alderman Election." GEMz participants designed the information requirements to support a political campaign for a fictitious Chicago alderman and implemented a database application. A female DePaul CTI faculty member and a female DePaul PhD student guided GEMz participants on how to design and implement a database using Access software. In addition to the database application, a DePaul graduate alumna led the teams in a multi-media component of the camp, where the GEMz teams designed, filmed, and edited a 30-second campaign commercial using Premiere software.

The GEMz 2004 program was "Promoting Community-Based Organizations through Digital Cinema." That year, three of the six counselors were former GEMz participants. This new feature of the program incorporated two additional benefits: (1) it allowed the program managers to continue to mentor prior GEMz participants who had taken on additional leadership responsibilities as camp counselors; and (2) the counselors earned money that could be used for college expenses. Each team was asked to unite their creative and technical talents to produce a digital film for one of six Lawndale Christian Development Corporation (LCDC) outreach programs. LCDC is a community-based organization established in 1987 by Lawndale Community Church to bring revitalization to the lives and environment of Chicago's Lawndale residents through economic empowerment, housing improvements, educational enrichments, and community advocacy. Over the course of six days, GEMz participants learned the documentary production process and were taught how to shoot and edit a 3- to 5-minute documentary through the utilization of iMovie, a movie editor software package.

Tier II: Enhance Basic Life Skills

Along with daily technology instruction, GEMz teams participated in personal development workshops. Participants attended Money Management and Public Speaking workshops, competed in team challenge activities, attended a conflict resolution session, and participated in a community service project. The objective of the money management workshop was to guide the teams through a high-level overview of the categories required for their organizational budgets. The teams were instructed to consider both start-up and ongoing expenses. Teams were also encouraged to brainstorm and document the revenue portion of their business endeavors. The Public Speaking workshop was created to prepare GEMz participants for the formal presentation of their project that occurred at the end of camp. Specific techniques were presented on how to organize presentations and strengthen oral communication skills. DePaul University's Team Challenge workshop consisted of a series of physically and intellectually challenging, competitive activities designed to assist the teams to build trust amongst team members, develop greater communication skills, and enhance collaborative problem-solving skills. Immediately following the team challenge activities, debriefing sessions were conducted to allow team members to evaluate their interactions. GEMz participants also attended a Conflict Resolution session to further develop their interpersonal and team skills. This session equipped GEMz participants with a variety of tools and techniques to help them resolve conflicts that might arise in their intra/inter team activities throughout the week.

Tier III: Promote Positive Self-Images and Encourage Social Interaction

Each evening, GEMz participants engaged in social development workshops. These workshops promoted positive self-image and social interaction. Activities included movies, sports, self-defense, African and Salsa dance, Holistic Me, and Reflections. In the Holistic Me workshop, the speaker discussed the multi-dimensional aspects of a person. During this workshop the participants were instructed to value their whole being, while emphasizing their individual self-worth and value. The speaker acknowledged that it was important for GEMz participants to look beyond their physical characteristics and be cognitive of their mind, their heart, their character, and their soul. For this reason the workshop was named, "Holistic Me—my mind, my body, and my soul. Who am I?" During the Reflection sessions, GEMz participants were allowed time to quietly reflect on their camp experience and record them in personal journals. They were also encouraged to share their thoughts with the group to further stimulate social interaction. GEMz participants broadened their sense of social responsibility through participation in a community service activity. For two consecutive years, GEMz participants assisted the staff of Boulevard Arts Center in a landscaping beautification project. The community service activity gave them the opportunity to see themselves not only as an individual, or as a member of a team, but also as a valued contributor to their community. To further promote inclusion, GEMz participants were continuously exposed to female IT professionals. Program managers, counselors, and speakers were all women who held numerous IT positions including chief information officers, IT directors, network engineers, IT consultants, IT project managers, IT professors, and IT undergraduate and graduate students.

RESULTS

The three summer GEMz programs described here were developed by merging several of the previously stated strategies. The programs explored the potential value of using a holistic approach to interest high school girls in the IT field. Evaluation forms were administered at the end of each camp. The objective questions on the evaluation form used a 5-point Likert scale. GEMz participants indicated that they agreed or strongly agreed that 90.6%, 94.0%, and 100.0% of the workshops and activities were interesting for the 2002, 2003, and 2004 programs, respectively (Table 1). We also know that GEMz is effective in stimulating the interest of some girls in the IT field. Although most GEMz participants have not yet completed high school, three young women have applied to CTI as a direct result of attending the GEMz program.

The majority of open-ended survey responses were also positive, and reflected the holistic nature of the program, as can be seen in the representative comments in Table 2.

Table 1. Overall participant evaluations

Program year	Number of participants	Evaluation return rate	No. of high schools	% of activities rated interesting
2002	27	92.6%	8	90.6%
2003	42	88.1%	25	94.0%
2004	36	72.2%	20	100.0%

Table 2. Representative open-ended responses

Tier I (Technical Skills) comments:
I learned how to use FrontPage and make a web site. That was new to me.
The most beneficial aspect of the day was lab time because I learned a lot of info about Access database.
Filming and editing the documentary. It was very fun and interesting and it gave me some ideas on what I might do in college and when I graduate from college.
Tier II (Basic Life Skills) comments:
The Money Management workshop made me realize the importance of budgeting.
Getting a chance to speak in front of everybody was a nice experience.
Tier III (Positive self-images and social interaction) comments:
The Self-Esteem class was very interesting and I learned a lot about society with the statistics that the teacher gave us. It talked about other teenage girls like me and how they felt about themselves.
I really appreciate being here. I learned a lot of things about myself and I also learned how to make myself a better person and how to react to challenging things…
The most beneficial aspect of the day was conflict resolution, which was four ways to solve the conflict. Listen, understand, respect, and resolve.

FUTURE TRENDS

Originally, the GEMz program was established by four female IT graduate students who yearned to interact with more female colleagues. The program now helps high school girls recognize the societal context of IT, while at the same time helping to develop their minds, hearts, and souls. This holistic approach is perhaps the greatest contribution of the GEMz program. It is possible that the long-term key to expanding the role of women in technology lies with the nature of the holistic approach pioneered by GEMz. As GEMz alumni move from high school through college, they will be tracked to determine if their interest in IT continues. While the actual number of girls affected by the GEMz program is relatively small, the potential impact of the program in demonstrating the viability of the holistic approach is vast.

CONCLUSION

Various barriers have been identified and possible solutions have been recommended to break the self-perpetuating cycle of low female interest in IT. Some barriers seem simplistic, with relatively straightforward resolutions, (e.g., tell girls about true attributes of the IT industry). Others exist in the very essence of our current societal norm and require extensive social change, (e.g., educators must learn to understand gender stereotypes in computing and create a bias-free environment). This article only addressed a minute segment of the under-representation issues in the IT industry. For example, retention issues were not addressed, nor were minorities or people with disabilities. IT stakeholders must continue to develop and evaluate a comprehensive collection of intervention strategies to create a truly diverse IT environment. The GEMz program has demonstrated that those strategies should include a holistic approach that addresses the multiple dimensions of people's lives.

KEY TERMS

Basic Life Skills: General skills that can be useful across numerous professions or in every day life, (e.g., money management, team building, effective oral and written communication, and conflict resolution).

Career Interest Barriers: Actual or perceived factors that discourage an individual from choosing a specific career.

Female IT Role Models: Women in the profession who are successful in the IT field and willing to mentor others. It is essential for these role models to be visible to young women who are deciding upon a career path in IT.

Geeks and Hackers: Margolis and Fisher (2002) describe these individuals as " … in love with computers, myopically focused on them to the neglect of all else, living and breathing the world of computers … " (p. 65). The major difference in the term hacker relative to geek is a hacker also means a person who gains unauthorized access to other computers.

Holistic Approach: A broad strategy designed to integrate multiple aspects of a topic. In the GEMz program, the holistic approach was a program design strategy created to address multiple aspects of the participants whole being; their minds, hearts, bodies, and souls.

Shrinking Pipeline: Tracy Camp (1997) describes the shrinking pipeline condition as "the ratio of women involved in computer science from high school to graduate school has been dwindling at a startling pace ... " (p. 103).

Technical Skills in a Societal Framework: A focus on technical skills as they relate to solving or enhancing a community issue.

Funding Women in Science, Engineering, and Technology in Ireland

Ita Richardson
University of Limerick, Ireland

INTRODUCTION

In the mid-1990s, I was one of a number of women who recognised the importance of having an on-campus child-care facility for staff and students at the University of Limerick.[1] Up until our child-care facility, Silver Apples, opened in November 1999, we had no on-campus child care available to us. The facility opening was due mainly to the efforts of a small group of women who used many opportunities to talk to management about the issue we had. As a direct result of this lobbying, the University of Limerick applied for and received funding; this would partly fund the building of the facility. More recently, the facility's management, in conjunction with our local primary school (first level), opened a purpose-built after-school club, the first of its kind in Ireland.

This anecdote is an indicator of how Irish society saw the need for child care 10 years ago: It was not high on the political, educational, or business agenda. During local elections at this time, I spoke with politicians about the issue of child care. Many of them had not come across this as an issue previously, or else they chose to ignore it.

Things have changed! One of the current hot political topics in Ireland is the provision of child care to all sectors of employees. It is discussed in the media and in political circles. Questions are being asked as to how this will be funded: whether working parents can claim tax allowances or the government will make direct payments to the facilities providing child care. This change in attitude has come about not solely because of lobbying, but also because the demand for child-care provision in Ireland has grown significantly. In recent years, the workforce demographic has changed. Women are staying in or returning to the workforce, and this is being encouraged at the highest levels within our government. The changing child-care situation is an indicator of this.

In Ireland, the economy performed very well throughout the 1990s. This improving economy has given an opportunity to women to return to the workforce. In 1990, less than 36% of women aged 15 and over were employed; in 2004, this statistic increased to 45% (Central Statistics Office, http://www.cso.ie). Women return to the workplace after becoming mothers and so take maternity leaves and/or parental leaves, which may be as short as 4 months and as long as 2 years. Furthermore, women who broke their career paths to become full-time parents, which may have extended to 20 years, are also returning to work.

BACKGROUND

Women working in science, engineering, and technology (SET) may experience difficulties in returning to a workplace where the nature of their jobs has changed significantly, even in a short number of years. Furthermore, young women are not taking up SET third-level options. For example, at the University of Limerick, less than 10% of engineering students are women. Internationally, people (mainly women) currently in SET careers have shown concern about these two issues, and in many countries, networks have been set up to promote SET careers to women. These networks provide initiatives to promote SET choices that are available to both groups of women: those returning to SET careers and those considering SET careers. It is not a case of requiring all women to take SET options: We do not want to see square pegs in round holes. What is required is that women are given choices and can make those choices freely.

In Ireland, once such network is Women in Technology and Science (WITS). WITS was inaugurated in November 1990 to actively promote women in technology and science in Ireland. It does this through running initiatives such as role-model days and mentoring, and until recently, it was often a requirement for volunteers to organise and run such initiatives. However, that too is changing. The Irish government is recognising the value of retaining and retraining talented people. Consequently, initiatives have been instigated to support women returning to work. Some of these initiatives focus on actions, like the provision of child care, others on sectors, for example, women in rural areas and women in disadvantaged areas. What we are interested in are those initiatives that focus on SET.

Initiatives at the National Level

Recent women-in-SET initiatives include some funded by Science Foundation Ireland (SFI) through the National Development Plan (NDP) Equality for Women Measure.

National Development Plan: Equality for Women Measure

The NDP is a major development plan involving an investment of 52 billion euro of public, private, and European Union funds during 2000 to 2006. Covering investments in many aspects of the development of our economy, there is a specific requirement for gender mainstreaming throughout the plan. In addition, as a support to gender mainstreaming, the Equality for Women Measure is a positive-action program that complements this. Through this measure, 70 organisations have been funded to undertake positive-action projects for women. The specific objectives are as follows:

- Improve women's access to education, training, and employment
- Achieve equality for women in the workplace and in business
- Increase the number of women participating in decision making (Department of Justice, Equality and Law Reform, 2003)

While much of the funding from the Equality for Women Measure did not go specifically toward science, engineering, and technology projects, many women who are pursuing careers in these areas benefited. Furthermore, some projects were SET focused. Through this funding, WITS (2005) was enabled to produce a directory of SET women who are qualified for and available to sit on state boards. Tallaght Institute of Technology have instigated a mentoring program, Mentorlink.ie (2005), for young women in SET. Funding from this initiative has given the opportunity to the University of Limerick and the Limerick Institute of Technology to jointly run a foundation course in science, engineering, and technology for women. This course is discussed in detail later.

Science Foundation Ireland

Science Foundation Ireland is a statutory body that administers Ireland's Technology Foresight Fund. Through an investment fund of 646 million euro (2000-2006), it provides financial support for research in biotechnology and information and communications technology. SFI is interested in promoting cooperation between education, government, and industry in these two research disciplines.

Recently, Science Foundation Ireland announced a fund for the promotion of research among women. It states, "SFI's Objective is to encourage and participate in the development of sustainable mechanisms and practices which will ensure that women have an equal opportunity to compete on the basis of their scientific expertise, knowledge and potential" (http://www.sfi.ie). It has provided planning grants to 11 third-level institutions (universities and institutes of technology), giving them an opportunity to assess "women's participation in science and engineering research activities and research management." Following this planning period, SFI will be funding up to three development grants in 2006, each worth up to 250,000 euro, allowing third-level institutions to implement "long-term sustainable initiatives" for such participation. In the University of Limerick, due to the receipt of a planning grant, we interviewed faculty and postdoctoral and postgraduate researchers to investigate what positive actions for women's SET development can be taken within our institution.

In addition, SFI has announced Principal Investigator Career Advancement Awards that are designed to support people, particularly women, who have broken their careers for parental or caring responsibilities. This funding for individuals is worth up to 200,000 euro per year for 3 or 4 years, and allows for part-time as well as full-time research.

Foundation Course in Science, Engineering, and Technology for Women

A joint initiative run by two third-level institutions, the University of Limerick and Limerick Institute of Technology, is a certificate in foundation studies in science, engineering, and technology for women. This course was originally run during academic year 1999 to 2000, and due to its success and funding received from the Irish government's National Development Plan Equality for Women Measure, it is continued to be made available. This initiative in third-level access was targeted at women aged 22 and over who were unable to avail of third-level education through the traditional routes for a variety of reasons. The provision of a third-level foundation course is a central plank of the strategy for improving access to third-level education for the targeted group, and students who successfully complete this course are able to progress through the certificate, diploma, or degree route in courses at either third-level institution. The foundation course was designed and developed by an ad hoc working group consisting of four women and one man drawn from key departments in both institutions. Depending on resources, we aim to take 16 to 20 students annually.

The aims of the course are the following:

- To introduce students to a third-level environment
- To equip students with requisite knowledge for moving into third-level education
- To equip students with skills that help to further their knowledge
- To build up students' confidence in their ability
- To expose students to the basics of science and technology

Motivation of Staff

The staff members involved in this initiative volunteered to sit on the course design team. This was done in addition to their normal teaching, research, and administrative duties. What was the motivation for taking on this extra work? The staff members themselves recognise the importance of giving mature female students opportunities that are not available otherwise. We had seen the success of similar courses in other institutions such as Galway Mayo Institute of Technology and Tallaght Institute of Technology. One staff member had personal contact with a woman who had grasped at this opportunity for second-chance education and was in the process of completing a third-level degree. All of the team members work in institutions that have minimal numbers of women employed in our disciplines. The women on the team have experience of the opportunities that our predecessors—women who have been our role models—have given to us and believe it is important to offer similar opportunities to others.

Academic Course Structure

As with any course design, there were many discussions as to what modules should be provided and at what level. The approved course consisted of the subjects listed in Table 1 split over two 10-week semesters.

The foundation course is 1 academic year in duration. In the autumn semester, students are exposed to foundation courses in science and technology, and also provided with transferable skills such as study and project-presentation skills. Dur-

Table 1. Academic course structure

Term 1	Term 2
Science Foundation Course 1	Science Foundation Course 2
Introduction to Information Technology	Introduction to Electronics and Computing
Foundation Mathematics 1	Foundation Mathematics 2
Communication Skills	Foundation Course Project

ing the second semester, students study these subjects in more depth. They undertake a group project. This provides them with an opportunity to assimilate what they have already learned into an area in which they have a specific interest. Underlying both semesters are a communications and career-guidance stream and a mathematics stream. Evaluation of performance is by the assessment of projects and by formal examinations scheduled as for traditional students.

Nonacademic Course Structure

The course is time-tabled for 4 days each week, with Friday left free for mentoring meetings with study advisors, project work, and private study time. In order to facilitate women who have family commitments, including dropping off and picking up their children from school, classes run from 10:00 to 2:00 daily. Each student has a mentor who is a member of the course team and is available to meet students regularly. A life-skills module, dealing with issues such as time management, exam techniques, stress management, and relaxation, is also made available to the students.

Lecturers on the course were facilitated to consider how teaching adults would be different from teaching traditional students. They were made aware of boundary setting and of the counseling service available to the students.

Management

The course leader is a permanent member of the faculty at the University of Limerick. The course board consists of the manager, a member of the Department of Adult and Continuing Education at the University of Limerick, the course leader (chair), and representatives from the Limerick Institute of Technology and from various University of Limerick departments. Lecturers in the course are employed from the approved pool of staff at both institutions.

Progression from the Foundation Course in SET

Upon completion, students are expected to be confident about progressing directly into one of the institutions in order to embark on a longer term course. Successful candidates have an enhanced opportunity to experience third-level education, and the majority of students proceed into mainstream certificate, diploma, and degree programs in one of the participating third-level institutions. This route gives the student the option to break down their further education into stages. They can obtain a certificate after 2 years, a diploma after 3 years, and a degree after 4 years. This gives them progressive options and therefore can be more attractive to mature students as it is not as daunting of an undertaking as a 4-year commitment. When they apply for mainstream courses in each of the institutes, their successful participation in the foundation course is taken into account.

Since the course began, 60 women have completed it successfully. There has been a dropout rate of 15% of those who commence the course. The number progressing to third-level mainstream education justified the running of the foundation course. During this time, approximately 60% of students have commenced studies within third-level institutions, and a further 30% have commenced either full-time or part-time employment. Furthermore, some students have completed their third-level education and have graduated with certificates and degrees such as a certificate in business computing, BSc in business computing, BSc in environmental science, and BSc in industrial chemistry. It is also notable that the majority of graduates from the foundation course go on to become honours graduates from their third-level courses.

Based on the progress of the students who have completed the course, we are satisfied with the way the course ran. There are some considerations that we continue to keep in mind.

- It is important for students to be able to attend the course on campus, particularly in light of the aim of students continuing into third-level education.
- Research into the effectiveness of this and other similar programs is needed.
- The level of computing skills can be disparate.
- Facilities in the third-level institutes, particularly for science, are overadequate. For example, we would have liked to use a combined physics-chemistry laboratory, which is common in second-level schools in Ireland, but only

had separate third-level physics and chemistry laboratories available in the third-level institutions.

Other successes noted were the following:

- The spirit within the class and the feedback from the students was positive and encouraging.
- As a joint venture between two institutes, it was successful.
- On a personal level, staff enjoyed the opportunity for collaboration.

The importance of the communications and career-guidance stream should not be underestimated, particularly with a course such as this one. We were dealing with students who mainly either had not been in the workforce for many years or had not had the opportunity for further education. As well as providing scientific and technical knowledge, it was seen as important to give them support and advice in their career development. This was given during various discussions on the following topics:

- Job market
- Subject matter of possible courses
- Available options including ab initio degrees and the certificate, diploma, and degree routes
- Completion of college application forms

As stated by one of the external examiners, this was "a very worthwhile course which seems to have been well received by the students." Some of the students have gone into related further studies, thus indicating the success of the course.

FUTURE TRENDS

Ireland's child-care issue demonstrates visibly that women want to be given the opportunity to return to work. Because of the availability of funding from the National Development Plan and Science Foundation Ireland, we have the opportunity to make the return to science, engineering, and technology more attractive and available. Unlike what has been previously available, there is now funding available for those of us already involved in SET to promote SET careers to other women, thus offering choices to them that did not always exist in the past. The expectation is that the number of women pursuing SET careers in Ireland will increase.

CONCLUSION

Now that funding is being provided by the government, we should not forget the women who have given voluntary time—from weeks to years—to promote SET to women who would otherwise not have been made aware of available options, nor should we forget those women who brought SET issues to the political agenda. Funding is becoming more available, and within SET, I look forward to women having that choice, being involved in decision making, and becoming more involved in shaping our technological society.

KEY TERMS

Ab Initio Degree Course: Students enroll in a course of study for 3 or 4 years, and if they attain the required standard, they are awarded a bachelor's degree. They do not have the option of receiving other awards during their course of study.

Certificate, Diploma, and Degree Courses: Students enroll in a certificate course, and if they attain the required standard, they can then enroll in a diploma course. If they attain the required standard for their diploma course, they can then register for a bachelor's degree course. Each course takes 1 to 2 years and gives students an option to break down their further education into stages.

Direct Payments: Situation in which the government gives a child-care facility payments toward the cost of running the facility.

Equality for Women Measure: An initiative in Ireland run by the Department of Justice, Equality and Law Reform under the National Development Plan and supported by the European Union. It supports projects specifically focused on improving opportunities for women in Ireland. Gender mainstreaming is one of the objectives of the Equality for Women Measure. (http://www.ewm.ie)

Honours Graduates: In Europe, students may get bachelor's degrees at the honours level, which indicates that they have reached a specific standard in their degree course.

Tax Payments: Situation in which revenue commissioners give a tax credit to an individual who is paying for the cost of child care.

Third-Level Access: Providing the opportunity for people to participate in third-level education.

ENDNOTE

[1] In Ireland, child care is paid for by the parents of the children and is normally organised privately. There are very few government-run or subsidised facilities available to parents.

Gender and Chat Forums

Janet Armentor-Cota
California State University – Bakersfield, USA

INTRODUCTION

Within the last decade, the Internet has become one of the fastest growing technologies. According to research conducted by the Pew Internet and American Life Project, nearly 60% of the United States (U.S.) population is now online, with variation based on race, age, education, region and income (Spooner, 2003). Despite the persistent discrepancies in access, Internet usage among the U.S. population is steadily increasing, up by 9% since 2000. Throughout the 1990s, well-educated white men primarily populated the Internet; however, this situation has changed in the last 5 years. As of 2000, women made up 50% of Internet users and "Hispanics [were] just as likely to be online as whites, and African Americans are coming online at accelerating rates" (Horrigan, 2000, p. 2). Overall, the Pew study found that activities such as e-mail (and other online communication forums); online shopping; Web surfing; connectivity with family and friends; hobbies; news; and information are popular online uses. Through the Pew Institute's many studies, it is clear the Internet is a key aspect of social life in U.S. culture.

BACKGROUND

A particularly popular online activity is chatting. A variety of chat forums are in existence, including multi-user domains (MUDs), Internet relay chat (IRC) and Web chat. The very first form of chat was IRC; it was designed to allow a large number of people from different locations to chat among themselves. The initial protocol of IRC was designed in Finland by Jarkko Oikarinen in 1988, and since then, it has spread to more than 60 countries worldwide. Chat rooms such as IRC house a form of computer-mediated communication (CMC) or interaction that occurs in "real time: All participants in an interaction must be electronically present at the same time, and messages are immediately transmitted through the intermediate servers to all participants, wherever they may be" (Paolillo, 1999, p. 3). Chat rooms are constant and channels (specific chat rooms) are occupied 24 hours a day. Web chat rooms are differentiated from other chat forums by their multimedia character. They incorporate typed messages, voice communications, emotional cues (emoticons) and, sometimes, video streams.

GENDER AND CHAT FORUMS

Many studies explore the role of gender in chat forums (Armentor, 2005; Sunden, 2002; Kendall, 2002; White, 2001; Ignacio, 2000; Parks, 1999; Yates, 1997; Roberts, 1999; Herring, 1999; Soukup, 1999; Danet, 1998; Rodino, 1997; Turkle, 1995). Table 1 offers a list of key findings on the issue. Most research on the relationship between gender and chat forums focuses on the issue of identity.

Rodino (1997) found in her study of IRC that gender is more of a performance than a binary category. Furthermore, she found gender construction is not divorced from *real* life, but is allowed to be multiple. Findings demonstrate that for some, gender "is made to be more 'real' than it really is" and for others "gender's performativity is rendered more 'virtual' than it really is" (Rodino, 1997, p. 18).

For her research on MUDs, Kendall (2002) conducted an ethnographic study that addressed issues of gender identity. Based on her findings that demonstrated participants often reproduced hegemonic versions of masculinity, Kendall (2002) argues that "online relations do not occur in a cultural vacuum. However much people may desire to leave behind the constraints of their off-line cultural backgrounds and social identities, their social interactions online remain grounded in understandings and contexts that intersect with off-line real identities" (Kendall, 2002, p. 225). Armentor (2005) found in her research of a Web chat forum that there were many more performances of dominant gender identities than there were acts of transgressive identities. However, she also demonstrates that for many participants, the Web chat forum is a space for them to experiment and play with sexual identity. She notes that for some female chatters, this may be especially appealing. During cybersex, one can perform versions of sexuality without the dangers of face-to-face relations.

On the topic of gender harassment in synchronous and asynchronous forums, Herring (1999) used a linguistic approach to analyze talk from each forum. She found that in both forums, the rhetorical gender dynamics were the same. That is, she observed that online gender harassment followed a certain sequence, which included: "(non)provocation, harassment, resistance, escalation, compliance" (Herring, 1999, p. 164). Herring, Johnson and DiBenedetto (1995) explored the claim that "men dominate computer-mediated interaction much as they dominate face-to-face interaction: by 'talking' more, by taking an authoritative stance in public discourse, and by verbally harassing and intimidating women into accommodation or silence" (Herring et al., 1995, p. 67). They found these forms of interaction were common in two mixed-sex discussion groups. However, they observed women participating in resistance strategies. Armentor (2005) found striking examples of discursive gender harassment and homophobia in the Web chat room she studied. However, she also noted that there were many instances of discursive resistance to gendered dynamics. Some participants who were the target of discursive oppression resisted through reframing issues and fighting back with words.

FUTURE TRENDS

The complexities of online social life are only beginning to be understood by researchers. As Internet research continues to grow and explore these complexities, new findings are constantly surfacing. A variety of chat rooms are in existence, used for a variety of purposes. Within these virtual communities, regular participants establish their own set of norms. However, flaming (an attacking message) is often a problem for many virtual communities, especially chat communities. In addition, some chat rooms are clogged with bots (software robots that simulate human chatters) that attempt to lure chatters into Internet pay porn sites (Armentor, 2005). However, chat spaces may also offer participants a common meeting ground and the possibility of meeting new people without the fear of physical harm (Armentor, 2005).

CONCLUSION

Chat forums are simulated hangouts or places to go when people are looking to meet new people with similar interests. They are not separated from the off-line world. They are places and spaces very much connected to off-line social life and structures, especially when it comes to gender, sexuality, race and ethnicity. Chat forums also offer many new opportunities for resisting these structures and forming new types of communities. As the Internet continues to expand throughout society and as more research is conducted, new questions arise about how network spaces, such as chat forums, contribute to everyday social life.

KEY TERMS

Chat: Real-time communication between two users via computer. Once a chat has been initiated, either user can enter text by typing on the keyboard, and the entered text will appear on the other user's monitor. Most networks and online services offer a chat feature.

Chat Room: A virtual room where a chat session takes place. Technically, a chat room is really a channel, but the term *room* is used to promote the chat metaphor.

Cyberspace: A metaphor for describing the non-physical terrain created by computer systems. Online systems, for example, create a cyberspace within which people can communicate with one another (via e-mail), do research or simply window shop. Like physical space, cyberspace contains *objects* (files, mail messages, graphics, etc.) and different modes of transportation and delivery. Unlike real space, though, exploring cyberspace does not require any physical movement other than pressing keys on a keyboard or moving a mouse.

Emoticon: Short for *emot*ion *icon*, a small icon composed of keyboard characters and used in e-mails and instant messaging that indicates the mood and/or emotion of the writer. Because of the nature of written text, which doesn't rely on vocal inflection and facial cues to communicate attitudes such as sarcasm and humor, the writer's tone is often not apparent. Emoticons, when read sideways, mimic facial expressions and, therefore, relay the emotion behind an expression.

Fasgrolia: The name for the fast-growing language of abbreviations, initialisms and acronyms.

Flame: A searing e-mail, newsgroup, or chat message in which the writer attacks another participant in overly harsh, and often personal, terms.

IM: Short for *i*nstant *m*essage, a type of communications service that enables you to create a kind of private chat room with another individual to communicate in real time over the Internet, analagous to a telephone conversation but using text-based, not voice-based, communication. Typically, the instant messaging system alerts you whenever somebody on your private list is online. You can then initiate a chat session with that particular individual.

Lurk: To eavesdrop on a chat room. In most online areas, lurking is perfectly acceptable behavior and is, in fact, encouraged so that you get the feel of the area before posting your own comments.

Netiquette: Contraction of Internet etiquette, the etiquette guidelines for posting messages to online services and, particularly, Internet newsgroups. Netiquette covers not only rules to maintain civility in discussions (i.e., avoiding flames), but also special guidelines unique to the electronic nature of forum messages. For example, netiquette advises users to use simple formats because complex formatting may not appear correctly for all readers. In most cases, netiquette is enforced by fellow users who will vociferously object if you break a rule of netiquette.

World Wide Web: A system of Internet servers that support specially formatted documents. The documents are formatted in a markup language called HTML (*HyperText Markup Language*) that supports links to other documents, as well as graphics, audio and video files. This means you can jump from one document to another simply by clicking on hot spots. Not all Internet servers are part of the World Wide Web.

Gender and Computing at University in the UK

Ruth Woodfield
University of Sussex, UK

INTRODUCTION

In the late 1970s, women's progress and participation in the more traditional scientific and technical fields, such as physics and engineering, was slow, prompting many feminist commentators to conclude that these areas had developed a near-unshakeable masculine bias. Although clearly rooted in the domains of science and technology, the advent of the computer was initially seen to challenge this perspective. It was a novel kind of artefact, a machine that was the subject of its own newly created field: "computer science" (Poster, 1990, p. 147). The fact that it was not quite subsumed within either of its parent realms led commentators to argue that computer science was also somewhat ambiguously positioned in relation to their identity as masculine. As such, it was claimed that its future trajectory as equally masculine could not be assumed, and the field of computing might offer fewer obstacles and more opportunities for women than they had experienced before. Early predictions of how women's role in relation to information technology would develop were consequently often highly optimistic in tone. Computing was hailed as "sex-blind and colour-blind" (Williams, Cited in Griffths 1988, p. 145; see also Zientara, 1987) in support of a belief that women would freely enter the educational field, and subsequently the profession, as the 1980s advanced.

During this decade, however, it became increasingly difficult to deny that this optimism was misplaced. The numbers of females undertaking undergraduate courses in the computer sciences stabilised at just over a fifth of each cohort through the 1980s and 1990s, and they were less likely to take them in the more prestigious or research-based universities (Woodfield, 2000).

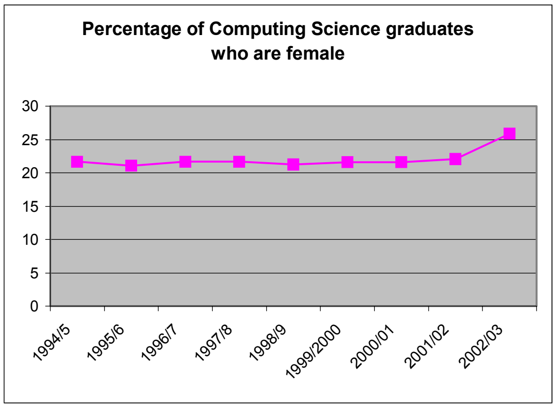
Tracy Camp's landmark article "The Incredible Shrinking Pipeline" (1997), using data up to 1994, plotted the fall-off of women in computer science between one educational level and the next in the US. It noted that "a critical point" was the drop-off before bachelor-level study—critical because the loss of women was dramatic, but also because a degree in computer science is often seen as one of the best preparatory qualifications for working within a professional IT role[1]. The main aim of this article is to examine how the situation has developed since 1994, and within the UK context. It will also consider its potential underlying causes, and possible routes to improvement.

BACKGROUND

In the UK, throughout the 1990s and into the new millennium, the achievements of secondary school-age girls (11-16 years) progressed significantly in the more traditional scientific and technical subjects, and began surpassing those of boys. Before an age when some curriculum choice is permitted (14 years old), girls perform better in science. Furthermore, although fewer of them take science once they have choice, they continue to surpass boys' achievements in the area. Higher proportions of girls now gain an A-C grade pass in their GCSE examinations in chemistry and biology and physics (Department of Trade & Industry (hereafter DTI), 2005; Equal Opportunities Commission (hereafter EOC, 2004)). In terms of A levels, the qualifications usually taken at the end of the first two-year period of non-compulsory education (16-18 years), girls also proportionately achieve more A-C passes in these subjects (EOC, 2004).

Achievements in computing courses have followed this trend. Over the last decade, girls have gained around 40% of GCSE qualifications in computer studies, and they are now more far likely to gain an A-C pass than their male counterparts (EOC, 1994-2004). Nevertheless, at A level, when students traditionally specialise in three or four subjects, the trend has been for the majority of girls

Figure 1.



Note. Based on original analysis of Higher Education Statistics Agency data provided under ad hoc data enquiry: 23148

to opt out of computing. In 1993, in England, girls only accounted for 13% of students deciding to further their computing education to A level standard in England (EOC, 1994). By 2003, this picture had significantly improved, with girls comprising 26% of those studying computing or information technology A level (Joint Council for Qualifications, 2004). Although this still represents a substantial "leak" between one educational level and its successor, it is noteworthy that girls have recently become proportionately more likely to gain the top grades in these qualifications as well (DTI 2005; Joint Council for Qualifications, 2004).

COMPUTER SCIENCE AT THE HIGHER EDUCATION LEVEL[2]

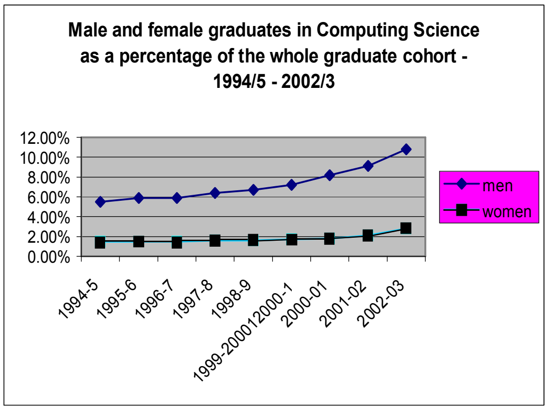
As Figure 1 indicates, the proportion of women within computer science courses at tertiary levels remained fairly static between 1994-2003, despite the improving proportion of them taking computer science at A Level over the same period. Although there appears to be a slight increase between 2002 and 2003, this is likely to be due to changes in the way graduate statistics in the UK were calculated between these two years[3]. On average, women comprised 22% of those completing a degree in the area over the period.

In the UK, female applicants to computer science courses differ in key respects from their male counterparts. They are especially likely to cite their interest in the subject as the main reason for studying it and are committed to finding the right course above other considerations, such as location of university and so forth (Connor, Burton, Pearson, Pollard, & Regan, 1999; Craig, Galpin, Paradis, & Turner, 2002b; Millar & Jagger, 2001). This interest would seem to be intrinsic, as they are less likely to cite future employment prospects as a motivating factor for their subject choice than their male counterparts (Millar & Jagger, 2001). Female computer science applicants have indicated that, in order to aid course choice, they review a wide range of information and are especially influenced by the information provided in university prospectuses and by experiences of pre-entry campus visits. Indeed, information deriving from universities is deemed far more helpful than advice from secondary school teachers and careers advisers (Connor et al., 1999; Craig et al., 2002b; Millar & Jagger, 2001).

Women are slightly more likely to be accepted for a degree within the broad area of mathematical sciences and Informatics, of which computer science is a subset, probably due to their better success rates at A-levels. They are also more likely to complete their degrees (DTI, 2005).

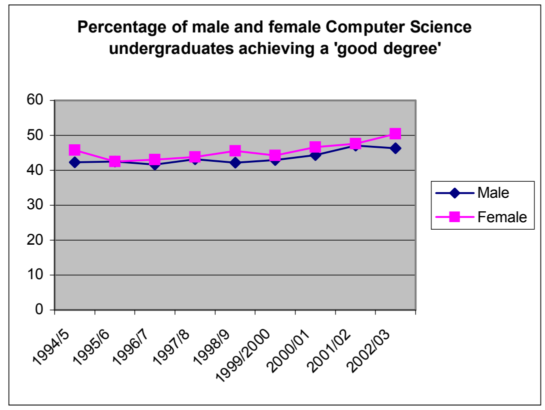
Once on their degree courses, although they are now over-represented within higher education as a whole (comprising 56% of new graduates), as Figure 1 has illustrated, women remain significantly outnumbered within each cohort of computer science undergraduates. This is in a context where computer science is attracting more undergraduates year-on-year whereas physics, chemistry, and engineering are attracting fewer, and mathematical sciences broadly the same numbers (DTI, 2005). As Figure 2 chronicles, between 1994/5-2002/3 the numbers of men and women completing degrees in this area in the UK climbed throughout the period, with the percentage of men climbing slightly faster than the percentage of women. In 1995, 5.5% of all male graduates qualified in computer sciences, as against only 1.5% of all females. By 2003, 11.8% of males were graduating in this area, as against 2.8% of females. While there are grounds for optimism insofar as the proportionate increases during this period for women were comparable to those of men,

Figure 2.



Note. Based on original analysis of Higher Education Statistics Agency data provided under ad hoc data enquiry: 23148

Figure 3.



Note. Based on original analysis of Higher Education Statistics Agency data provided under ad hoc data enquiry: 23148

it remains of concern that while more than a tenth of male graduates take their degrees in this area, less than 3% of females do. This is significant in the context of the link between computer science and professional-level IT work, and the critical role computer science knowledge plays in our society more generally.

Women are also generally under-represented among the academic faculty of computer science at university, although their numbers in Lecturer (28%) and Researcher (30%) ranks remains better than we might expect given their undergraduate representation (DTI, 2005). They are, however, disproportionately underrepresented in the more senior academic ranks (DTI, 2005).

Interestingly, however, as Figure 3 shows, of those taking degrees in this area, women fare no worse than men in terms of classification achieved, and their performance would seem to be improving. In 1994/5, 9.6% of men achieved the top grade of degree—a First Class—as opposed to 7.6% of women. By 2003, however, 11.9% of men were achieving this grade against 11.6% of men. Furthermore, women have also been marginally, but consistently, more likely to obtain a "good" degree—a First Class *or* Upper Second—than men since 1994, and by 2003 just over 50% of them achieved this standard as against just under 47% of men.

FUTURE TRENDS AND CONCLUSION

Once this picture is digested, we can see that there are some grounds for cautious optimism about the future: an increase in female participation at A level; improvements in female performance in relation to both pre-university and university qualifications; and evidence of above-average interest in computer science on the part of female undergraduates. Notwithstanding these changes, a key question is begged, however, given the context of the overall increase in the importance of the subject: Why is the under-representation of women that established itself in the field in the 1980s and 1990s not correcting itself more quickly?

It is still claimed by some that women are naturally less predisposed than their male counterparts to be attracted to, or to perform well within, the sciences in general (McCrum, 1996) and computer science in particular (Craig et al., 2002b). This position, however, is increasingly difficult to sustain in the light of changes in female participation and performance rates in educational computing, and the fact that there are significant local variations in the uptake and experience of university-level computer science courses (Cahoon, 2001; Craig et al., 2002b; Millar & Jagger, 2001). As

Cahoon has suggested, it is much more likely that social factors are at play to explain female under-representation as "women can and do succeed in Computer Science when conditions do not deter them" (2001, p. 1).

These "social factors" would seem from the evidence to fall under two main areas. First, females, including female computer science undergraduates, project a far more negative image of IT work than males. As their educational choices are so closely bound up with their projected career trajectories (EOC, 2001; Miller, Neathey, Pollard, & Hill, 2004), it is reasonable to assume that this tendency has impacted on female recruitment levels to the subject at university. Secondly, female experiences of computer science degrees would seem to be less positive than those of their male counterparts, and it is very likely that the stories of such experiences become part of the information young women draw on when making their decisions about what subjects to study at university.

To take the first point, the available evidence suggests that women taking computer science degrees, and courses that might prepare them for undergraduate study, are generally not likely to be fully aware of the benefits of a career in IT (Millar & Jagger, 2001; Peters, Lane, Rees, & Samuels, 2003), while simultaneously being more likely to be alive to its real and perceived disadvantages. They are more likely to project, for instance, that it will be solitary work, when they, as a group, have a preference for team-based and socially-embedded computing (Craig et al., 2002b). The problems facing them should they opt for a career in computing cannot be ignored, substantial as they are. Female computer science graduates are less likely than males to find employment at the end of their degrees, despite their tendency to have achieved a higher degree classification, and to be better educated more generally. Once in employment, they are likely to receive less pay for comparable work, and many describe a working ethos that systematically privileges men over women (Millar & Jagger, 2001; Woodfield, 2000). In a context where female educational achievements are outstripping those of males at every level of education in the UK, and female work aspirations are becoming increasingly clear and uncompromising, it is almost certainly the case that the negative perception of IT work plays a critical role in determining the numbers of women choosing courses that qualify them for it. As Millar and Jagger have claimed, problems appear in the relationship between women and the computer sciences "once women begin to structure their education towards a career" (2001, p. A-iv). There are substantial benefits to IT work, however, that could be clarified and communicated to those selecting their GCSE, A level and university courses: salary levels, notwithstanding the gender gap, tend to be higher than average; existing female IT professionals rarely describe themselves as bored or unfulfilled in terms of the work *per se*. More fundamentally than the need to communicate these benfits, the sector needs to consolidate the beneficial aspects of IT careers for women, and work to eradicate the more negative aspects.

The earlier communication about the advantages of IT work takes place, the better. It is claimed that educational choices, based on projected career costs and benefits, are already taking place when UK teenagers face their first opportunity to specialise, around age 14. This is also an age when young males and females are most sensitive to gender-appropriate and gender-inappropriate career choices. It is of concern then, that there seems to be so few reports of positive representations of professional IT work as a viable career goal for girls (and their parents) by teachers or careers advisers within secondary schools, and that the provision of female-friendly spaces for computing is still considered cutting edge (Craig et al., 2002b; Millar & Jagger, 2001; Peters et al., 2003). Improvements in the knowledge, and sometimes the attitude, of adults playing a key role in pre-university course choices, could make a significant difference to female participation rates at this level.

As well as the role played by the image of IT work, the reported experiences of those undertaking a computer science degree must also partially account for the level of female participation at university. There is a wealth of evidence to suggest that female students' under-representation on courses creates its own problems in terms of their confidence, adjustment, enjoyment, and achievement levels. They report themselves to feel pressurised to adapt to a male-dominated and male-oriented educational regime in order to survive (see, for example: Bjorkman, Christoff, Palm, & Vallin, 1998; Blum, 2001; Margolis & Fisher, 2002; Peters et al., 2003).

Evidence from those institutions that have attempted to make significant changes within their computer science programmes so that women will feel less alienated suggests that the have enjoyed far greater female participation and approval rates as a result (Connor et al., 1999; Margolis & Fisher, 2002; Millar & Jagger, 2001). In doing so, they point to a wish list of best practices for others interested in doing the same. These include building a curriculum that assumes a minimal level of previous IT experience, providing mentoring systems and female-friendly learning spaces, and ensuring that faculty are sensitive to the needs and abilities of female students (Blum, 2001; Cahoon, 2001; Hefce 2002; Margolis & Fisher, 2002). One course in the UK, where such considerations have been central for some time, reports high rates of female uptake of degree places, but also that 100% of women on the course maintained a desire to become an IT professional after the completion of their degree (Craig et al., 2002).

The finding that women are heavily reliant on the information provided in prospectuses is heartening in this regard. It confirms that there is a clear window of opportunity for the more progressive universities through which they can encourage potential applicants and reduce reliance on general anecdotal or impressionistic information that may not apply to their courses. If more institutions embraced the same ethos, a critical mass of women entering computer science undergraduate programmes could be achieved in the next decade. This, in turn, could impact significantly on the general culture of educational computing and beyond into the workplace, which could lead to improvements in the sector's image. The beneficiaries of this would not just be the women who would otherwise have turned away from the subject at degree level, but also the UK economy and society which is arguably at present drawing its computing scientists and skilled IT professionals from an artificially restricted pool.

KEY TERMS

Classification of Degree: UK degrees are ascribed "classifications" that usually correspond to the following percentage results (averaged over all assessments contributing to the final grade):

First – 70%+
Upper Second or 2:1 – 60-70%
Lower Second or 2:2 – 50-60%
Third – 40-50%
Pass – 30-40% (a bachelor degree without honours)

Equal Opportunities Commission/EOC: The Equal Opportunities Commission is an independent, non-departmental public body, funded primarily by the government. It provides free research reports and statistics chronicling the position of women and men in all aspects of UK life, including work and education. Web address: http://www.eoc.org.uk

GCE A Level: The General Certificate of Education, A level (Advanced Level) is usually taken 2 years after GCSEs and as a non-compulsory, pre-entry qualification for University-level Study. Students usually take 3 or 4 specialised subjects at this level, which they are free to select.

GCSE: The General Certificate of Secondary Education is usually taken by 15-16 year olds in a range of subjects—some compulsory (English, maths, and science) and some optional (including Computer Studies)—at the end of their compulsory schooling. Achieving 5 GCSE grades A-C is considered the desirable educational benchmark to be reached by this age.

Good Degree: A term used in academic literature and common parlance to indicate a degree which has been classified as an "Upper Second" or "First," (i.e., in the top two degree classifications. It is normally assumed that those going on to post-graduate study will have such a degree, and they are preferred in many employment contexts.

HESA (Higher Educational Statistics Agency): HESA was set up in 1993 by the UK Government to act as a central source for higher education statistics and has become a respected point of reference. Web address: http://www.hesa.ac.uk.

IT/Computer Professional: An individual working within the IT/computer sector within a complex and skilled role that is classified within the category "Professional occupations" (e.g., software engineers), or sometimes within "Associate professional and technical occupations" (e.g., computer programmers)—in the National Statistics classifications, Standard Occupational Classification Codes (2004): http://www.statistics.gov.uk

ENDNOTES

1 Elsewhere, degrees in mathematical sciences and/or business and administration degrees are included in analyses of gender representation within degrees associated with IT and IT employment (see, for instance, Millar & Jagger, 2001). Here, unless stated otherwise, I will be using the narrower group of "computer science" degrees, defined, according to Higher Educational Statistics Agency programme categories as including: computer science, information systems, software engineering, artificial intelligence, and other programmes within computer science.

2 All of the statistics included within this section are based on original analysis of Higher Education Statistics Agency data provided under *ad hoc data enquiry: 23148*.

3 HESA changed its discipline classification scheme between the years 2001/2 and 2002/3, making comparisons between pre-2002/3 data and post-2002/3 data problematic.

Gender and Differences in Online Teaching Styles

Karinda Rankin Barrett
Tallahassee Community College, USA

INTRODUCTION

Researchers interested in the role gender plays in the educational environment have investigated differences in the teaching styles of men and women in the face-to-face classroom (Caplan, 1994; Clegg, Trayhurn, & Johnson, 2000; Proost, Elen, & Lowyck, 1997; Statham, Richardson, & Cook, 1991; Sullivan, 1999). In distance education, the differences between the teaching styles of men and women are similar to those noted in the face-to-face classroom (Barrett, 2004; Dupin-Bryant, 2004). In both educational settings, men and women prefer different teaching styles. In the face-to-face classroom, differences in the teaching styles of male and female faculty members have depicted women as leaning more towards a learner-centered style than men, even though men and women are exposed to similar experiences in their own educational endeavors (Moulton, 1992; Scotney, 1986; Statham et al., 1991; Stickney-Taylor & Sasse, 1990). The purpose of this discussion is to use research on teaching styles to provide more information about the online environment for those who will be teaching, learning, or administrating online distance education.

BACKGROUND

Teaching styles have been defined in numerous ways. The following background sections lay a foundation for exploring teaching styles. The first section provides a general overview and definitions of teaching style followed by a brief section focused on the recent direction of online distance education. The subsequent section highlights gender theories with a focus on communication and decision-making. These areas are the main framework for understanding gender differences in online teaching styles.

Defining Teaching Styles

Teaching styles have been explored in a variety of ways. Grasha (1996) used categories to explore teachings. He offered five distinct teaching styles including Expert, Formal Authority, Personal Model, Facilitator, and Delegator. Conti (1978) created a continuum with a learner-centered style on one end and a teacher-centered style on the other. In order to highlight the details of teaching style, Conti used the continuum to develop seven factors: (1) learner-centered activities, (2) personalizing instruction, (3) relating to experience, (4) assessing student needs, (5) climate building, (6) participation in the learning process, and (7) flexibility for personal development. Each of these factors is also measured on the learner-centered to teacher-centered continuum.

Although Conti's Principles of Adult Learning Scale (PALS) was originally designed to describe teaching styles in the face-to-face environment, it has been researched and applied in numerous environments including the online environment. For the purposes of this discussion, Conti's PALS frames the differences in teaching styles based on gender.

Conti (1985a) defines teaching styles as a set of behaviors that are consistent regardless of the setting or course being taught. Numerous studies have validated this definition by demonstrating the consistency of teaching styles from setting to setting (Chanchaem, 2001; Totin Meyer, 2002). Although various researchers and theorists have defined teaching style as an instructor's set of behaviors that are consistent from setting to setting and from course to course, an instructor's teaching style falls within a range.

In the face-to-face classroom setting, Conti defined the learner-centered style as a "method of instruction in which authority for curriculum formatting is jointly shared by the learner and practitioner"

(Conti, 1985a, p. 7). He referred to the teacher-centered style as one where the instructor takes the majority of the responsibility for directing the learning environment. Others have characterized a teacher-centered style as one where instructors implement more traditional teaching techniques in an effort to transmit knowledge to the learners (Jarvis, 1995).

Educators over the years have argued the superiority of teaching styles. More recently, the argument has focused on *when* a particular teaching style is most useful (Miglietti & Strange, 1998). Although an occasional researcher has argued that one teaching style is the most effective including for the online environment (DiBiase, 2000), others have noted that an effective teaching style varies based on the content, the learners and the environment (Miglietti & Strange, 1998). Other researchers have compared the two environments and investigated the impact on teaching style when an instructor transfers a face-to-face course to the online environment. In such an instance, Chanchaem (2001) found no significant difference in the teaching styles of those who moved to an online environment.

Even though a variety of teaching styles are desirable, Conti's research along with that of a few others (Conti, 1985b; Miglietti & Strange, 1998; Post, Carusetta, Maher, & Macintosh, 1998) makes a viable argument for a teaching style that favors a learner-centered style because of more positive learning outcomes in classrooms where instructors implement such a style. In the community college arena, O'Banion (1997) has promoted the learning college which focuses on learner-centered activities as the most effective environment for meeting students' need for an education that is accessible anytime, any place, and any way. Regardless, no single teaching style meets the needs of all learning styles; each has its advantages and disadvantages. Exploring issues related to online distance education will further enhance this discussion on gender differences and teaching styles.

Online Distance Education

Online distance education, which has its roots in correspondence courses and has a long history of providing alternative access to education, has changed drastically over the past decade. Some institutions entered online distance education by encouraging faculty to move their correspondence courses to the Web. This mindset perpetuated the notion that students are empty vessels to be filled with the wisdom of an expert either through books or through some form of textual means of connecting with the content. As such, this notion would dictate a more teacher centered-style.

Educators and observers of the educational environment have often assumed that technology would alter the learning environment. Early studies of educational technology determined that the delivery method did not play a key role in altering the learning environment. Russell's (1999) No Significant Difference studies make the point that there is little difference between the face-to-face classroom and the online environment. Consequently, a learner may find the online educational environment similar to the face-to-face environment. The similarities may be greater now considering the history of online distance education.

Less than 10 years ago faculty were learning html and designing Web sites as a way to offer their courses online. At that time, the process for offering a course in the online environment was very tedious. Faculty often resorted to merely loading their notes to a Web site and calling it an online course. For students, interaction with the other learners and the instructor was limited as was interaction with the content.

Today, faculty members are using learning management systems (LMS) as a means of posting course materials and conducting activities on the Web. Some of the more popular LMS include Blackboard, WebCT, Desire2Learn, and Angel. The benefit of using an LMS is that faculty members do not have to learn a special language and the systems are designed to effectively facilitate the management of online courses. Additionally, the tools available in LMS can be used to create a more engaging and interactive environment including blogging features, wikis, discussion boards, survey tools, and testing functions. Through the use of these tools faculty are able to create a more engaging learning environment where students can discuss the content and collaborate on projects along with participating in numerous other activities.

Unlike the face-to-face environment, the online environment requires more preparation and planning. In the face-to-face environment, faculty can work from an outline, whereas in the online environment, faculty must identify, select, design, develop, and generally prepare materials ahead of time to address the topics on the outline. With the necessity of preparing in advance, faculty members have the opportunity to reduce the impact of their other roles including that of gender on their teaching styles. It also allows time to provide a variety of activities that will meet the needs of students' various learning styles and fit with a particular teaching style. The next section explains how gender theory is a background for understanding how gender relates to teaching styles.

Gender Theories

Gender communication theories provide a foundation for understanding differences in online teaching styles. On a very basic level, communication is at the heart of teaching. Consequently the differences in communication appear to parallel the differences found between teaching styles. Furthermore, the primacy of a gender role supersedes that of a secondary role such as that of being an instructor in the online environment. A brief review of gender communication and decision-making theories highlight some of the possible differences related to teaching styles.

Research (Belenky, Clinchy, Goldberger, & Tarule, 1986; Gilligan, 1982) showed that men and women differ significantly in the ways they communicate. Men on the average take on a role in communicating with others that can be characterized as an expert. Additionally, men are more likely to look at the overall picture and identify with an authoritarian role. Women, on the other hand, are more likely to prefer the role of a consultant while focusing on details and collaborating with others.

In very general terms, women tend towards a more collaborative manner of communicating emphasizing polite exchanges. They share examples from their personal experiences and strive to connect with the previous experiences of learners. Women are often more comfortable as a guide or a facilitator in the learning environment. Men tend to focus on creating status differentials. They are more comfortable functioning as the expert, the one in charge who possesses knowledge and expertise the students need to acquire.

The primary difference between the communication and decision-making styles of men and women centers on the ways in which they view and structure relationships. Men approach relationships as hierarchical structures where as women view them as networks (Gilligan, 1982). Decisions women make related to relationships are often influenced by a conflict between selfishness and sacrifice (Belenky et al., 1986; Gilligan, 1982). Men are more influenced by competing rights. Consequently, men address issues from a more abstract perspective and women take a more personal stance. (Gilligan, 1982). Differences in the ways men and women communicate and make decisions appears to carry over into their teaching style. Men's hierarchical approach to relationships lends itself to a teacher-centered style and women's network approach is most compatible with a learner-centered teaching style.

Although communication patterns vary by the context of a situation, regardless of gender, men employ a communication style that is more forceful, direct, and commanding than women who tend to communicate more politely, indirectly, and personally than men. Whether communication styles vary, they do impact how faulty teach online and what type of teaching style a faculty member adopts.

Gender and Differences in Teaching Styles

Regardless of whether gender is apparent in the online environment, it does play a significant role in the teaching styles that online instructors implement. Gender is not as readily apparent in the online environment because of diminished queues. Faculty members do not always post their photos and they may have a name that makes it difficult to determine their gender. Androgynous names such as Chris, Alex, and Lou, make it difficult to determine gender. Faculty members have the opportunity to "hide" behind the computer. Inhibitions related to gender role may also be reduced because visual feedback from students is not present. These notions contribute to the assumption that differences in teaching styles do not exist.

When the gender of the instructor is known, learners may form more specific expectations for teaching styles based on the instructor's gender.

Table 1. Differences in the teaching styles of women and men

Women	Men
Interpersonally oriented	Technically oriented
Allow students voices to be heard	Authoritarian
Actively engage students in learning	Socratic questioning
Cooperation and collaboration	Competition
Democratic discussion	Lecturing
Share personal information	Use examples from the text or others
Bridge students' experiences with their own	Abstract style
Listen to personal problems	Espouse information to students

Even if gender is not known, understanding a little about teaching styles may provide a basis for determining what a faculty's teaching style is and selecting learning strategies for a successful experience in the online environment. The best situation is one in which faculty share their teaching style with the learners so they have a better understanding of what to expect.

Research on teaching styles in the online environment is limited. Results of one study (Barrett, 2004) depicted differences in the online teaching styles of male and female community college instructors. Women demonstrated a more learner-centered teaching style than men in terms of their overall teaching style. Table 1 highlights the overall differences in teaching styles between women and men. The differences in activities and behaviors between genders show the ways in which faculty interact with students and the type of learning environments they create.

In the same study (Barrett, 2004), differences in teaching style were also apparent based on Personalizing Instruction, in which case, women were more likely than men to implement a more learner-centered teaching style based on this one factor in Conti's teaching style continuum. Differences in Personalizing Instruction demonstrated that women are more likely than men to exhibit some of the following behaviors:

- Use different teaching techniques and different materials for different students
- Let students work at their own pace
- Match instructional objectives to outcomes, abilities, and needs of the learners
- Encourage competition

When compared to communication theories, the differences in teaching styles are particularly interesting especially in the area of encouraging competition. In terms of teaching style, women tend to encourage competition, which is a male characteristic in communication styles. Differences may be attributable to the way male and female faculty use competition. To illustrate, women may use competition to bring teams of students together whereas as men may use competition as a way of creating status differentials. Although gender is not an absolute in predicting teaching styles, it may be a clue towards understanding them. The following section considers future trends and issues related to teaching styles.

FUTURE TRENDS

The future of online teaching styles will be similar to those styles that have been noted in other educational environments and differences between the teaching styles of men and women will persist in the online environment. Thus, Conti's definition of teaching style as a set of behaviors that is consistent from setting to setting will continue to hold true.

What has the potential to change in terms of online teaching styles is the instructional design process. As faculty members are developing online education, assessing teaching style is often omitted from the instructional design process. The focus of analysis in designing instruction centers on the characteristics and needs of the learners and issues surrounding the learning environment. These are essential areas of emphasis for an effective analysis, but those who are moving through an instructional design process should include an analysis of teaching style. Teaching styles is important because it has an impact on the learning environment and it affects the ways students learn. Instructors can provide information about their teaching style to enhance the success of students, which provides students with the information needed to create more realistic expectations in the online environment.

CONCLUSION

Learners in the online environment should find trends in teaching styles based on gender that reflect the face-to-face environment. Thus, students can expect to experience teaching styles that are similar to those they have previously experienced. As students and faculty move through their experiences in the online learning environment, current trends with teaching styles will most likely persist. Overall, assessing and understanding teaching styles provides faculty with a better understanding of their online teaching. For students, this information offers the opportunity to create realistic expectations so that students may receive the greatest benefit from their online educational experiences.

KEY TERMS

G

Blogging: Online journaling where readers can read text, view photos, listen to audio files, and comment on the information posted by an individual.

Discussion Board: A Web-based environment where participants can asynchronously express themselves. Discussion boards consist of three areas. A forum is the top level and it is used similarly to a folder. Within a forum are threads, which are the primary messages. Replies to a thread are called postings.

Learner-Centered Style: A teaching style that focuses on the characteristics, needs, and concerns of the learner.

Learning Management System (LMS): A Web-based program used as a platform for providing course materials and activities. Examples include Blackboard, WebCT, Desire2Learn and Angel.

Online Learning Environment: An educational environment where the emphasis is on learning as opposed to teaching and the educational process uses the Internet as the medium to transmit information and communicate.

Teacher-Centered Style: A teaching style that places the faculty and their issues, concerns and ideas at the center of the learning environment.

Teaching Style: An instructor's perceptions, beliefs, attitudes, and behaviors related to facilitating the learning environment.

Wikis: Web pages where more than one person can easily collaborate to edit a Web page. Often, no special programming skills are needed to edit a Web page and a history is kept which shows who edited the page, what they edited, and when.

Gender and Discourse Styles in CMC Learning Groups

Yong-Kwan Lim

INTRODUCTION

The evolution of computer-mediated communication (CMC) technologies has brought about changes in the landscape of education. This availability of technologies corresponds with the educational paradigms that are shifting towards the collaborative constructive conceptions of learning (Anderson & Garrison, 1998). To support interaction and cooperative learning among learners, online discussion groups are increasingly being incorporated into the courses of educational institutions.

Educators have deemed interaction as a vital component of collaborative learning (Sutton, 2001), and have provided an important framework comprising four types of interaction: learner-content, learner-instructor, learner-interface, and learner-learner (Hillman, Willis, & Gunawardena, 1994; Moore, 1989). Multiple studies have demonstrated interaction as a critical indicator of positive attitudes towards learning, higher achievement and increased motivation (e.g., Garrison, 1990; Fulford & Zhang, 1993).

If successfully implemented, groupware technologies could support group activities by providing an environment that enables more effective and efficient group communication (Benbunan-Fich & Hiltz, 1999). Benefits associated with collaborative online learning include the availability of time lag which enables learners to reflect on their own perspectives and the opportunity to promote co-construction of knowledge among peers (Bullen, 1998).

In order to facilitate effective construction of knowledge and interaction among learners using the CMC medium, it is critically important for researchers to understand what external factors would influence the interaction styles. In this regard, the current paper takes special note that the study of variations in gender discourse is an important area of research (Gunn, Mcsporran, Macleod, & French, 2003). To date, there has been a growing body of literature which examines the effects of gender on communication styles within an online learning environment. However, the results have been somewhat ambiguous and equivocal across the studies (e.g., Fahy, 2002; Savicki, Kelly, & Lingenfelter, 1996a), suggesting that the binary concept pertaining to gender may not be a useful basis for analysis of communication patterns among learners.

The purpose of this article is to discuss the communication styles of gender and propose a framework which seeks to identify contextual factors that would moderate gender interaction patterns within online learning groups.

BACKGROUND

Communication Styles of Gender

Prior gender-related research conducted in face to face (fTf) settings has indicated distinctions in the interaction patterns of males and females. Studies have revealed that females tend to use interdependent and socio-emotional language and express more non-aggressive behavior. On the other hand, males tend to be associated with task-oriented strategies, expressions of independence and assertions of vertically hierarchical power in their conversational patterns (Duran & Carveth, 1990; Tannen, 1994). In traditional learning environment, research has revealed that the "male learning" style is dominant to the extent that female students speak less in the classroom (Gilligan, 1982).

Analysis of written dialogue discourse in CMC shows that online interaction is a reflection of discourse in fTf mode. Herring (1993), in her analysis of a bulletin board, found differences in language style between men and women. Messages of females tend to be punctuated with "attenuated assertions, apologies, questions, personal orientation, and support", whereas characteristics of male's language include "strong assertions, self-promotion, rhetorical questions, authoritative orientation, challenges, and sarcasm" (p. 7). These findings are further supported by Blum (1998) and Savicki et al. (1996a) in their investigations.

Although the above studies provide evidence for gendered-related discourse styles, results are not consistent. The ethnographic work by Barrett and Lally (1999) revealed that although either gender displayed similar levels of cognitive content, male students exchanged more social content, and wrote longer messages. In contrast, females sent more interaction messages. Fahy (2002) found that despite being in the minority, women posted nearly as many messages as men did. In a study conducted on a graduate level online course, research results indicated that there were no significant differences in gender interaction styles (Wang & Sierra, 2003).

In general, there are two schools of thought concerning gender communication within the CMC medium (Rena & Keith, 2003). The first perspective maintains that CMC will provide a more democratic and egalitarian setting, in effect mitigating gender differences (Rena & Keith, 2003). Text-based CMC, with its loss of socio-contextual cues (Sproull & Kiesler, 1986), removes all cues associated with gender and social class. The second approach focuses on the view that gender differences in communication styles "transcend the medium" (Sussman & Tyson, 2000).

The above discussion implies that gendered-related discourse styles are fluid and elusive (Michaelson & Pohl, 2001). There is thus no compelling evidence to suggest that the communication patterns conform to the dichotomy of female vs. male categories. This further suggests that some accommodation must be made for the contextual specificity (e.g., work vs. school; collaborative task vs. competitive task) when understanding gender similarities and differences, a stance that is in line with the socio-contextual models of gender (Savicki, Kelly, & Lingenfelter, 1996b; Strough & Covatto, 2002).

According to the socio-contextual perspective, gender behavior emerges from the complex interaction between an individual and the contextual settings (Pickard & Strough, 2003; Strough & Covatto, 2002). Prior research studies conducted within the fTf environment indicates the importance of context dependence in gender-related behavior. For instance, females self-disclose more in social context, but males self-disclose more in collaborative context (Shaffer, Pegalis, & Cornell, 1992). Pickard and Strough (2003) found that males and females reported more feminine attributes when working with a partner of another gender than when working with the same gender during a collaborative task.

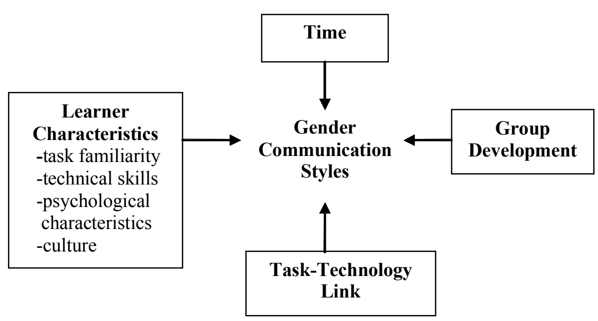
MAIN THRUST OF THE ARTICLE

A Conceptual Framework

As apparent from the preceding discussion, online gender discourse styles might thus be better understood by examining the immediate context (e.g., time) in which the interaction takes place, rather than solely the gender element.

In this section, we put forth a conceptual framework that identifies a set of contextual dimensions which may moderate the discourse patterns of gender in an online setting (see Figure 1). The following deliberates on the individual components of the proposed framework.

Figure 1. A framework of gender communication styles in online groups



Learner Characteristics

Task Familiarity/Technical Skills/ Psychological Characteristics

The individual student brings to the online group discussion a set of abilities and personalities. Prior experiences with CMC and subject expertise have been found to influence online discourse styles. Bielema (1997), in a survey conducted with graduate students distributed across remote sites, found that 28% of the e-mail posts were associated with technical difficulties. As females gained familiarity and confidence with CMC, they developed their linguistic style, in which the discourse shifted from more personal to professional (i.e., informational) (Wyatt, 1993 as cited in Yates, 1997). Sussman and Tyson (2000) found that women initiate discussions more frequently than men, particularly on topics that fall within the female-domain, in which females may have greater expertise (e.g., ballet and skating). Other factors which influence the participation rate include the psychological characteristics of online learners. Learners who experience communication apprehension will refrain from participating in online discussions (Sutton, 2001).

Culture

The culture of a nation can be viewed as the set of norms and values that differentiate populations of different societies (Hofstede, 1980). One of the more conceptually developed (Chang & Lim, 2002) cultural dimension in the literature is the individualism-collectivism aspect. Individualism-collectivism refers to the extent to which a culture fosters its people to promote a group's well-being and to endorse the desires of self over those of a group (Hofstede, 1980). Learners from a collectivistic culture tend to value relationships over task (Chang & Lim, 2002), while those from an individualistic culture are more opinion-oriented and straightforward (Ting-Toomey, 1992). Countries such as the USA are inclined towards the individualistic cultures, while those that lean towards collectivistic culture include most Asian countries, such as Singapore (Hofstede, 1980). Online homogeneously collectivistic groups were reported to exhibit better interaction, social behavior and response than homogeneously individualistic groups (Chang & Lim, 2002).

Previous research has indicated that culture moderates the impact of gender differences (Mortenson, 2002). Prior studies conducted in traditional settings have found that gender stereotypes, such as females valuing social relationships more, apply only to individualistic western countries (e.g., Watkins et al., 1998). A recent experimental study conducted within synchronous CMC settings revealed that there was no significant difference in perceived social presence between female-only and male-only groups, suggesting that previous research which found gender differentiation in communication styles may need more careful discernment (Lim & Lim, 2004). As the subjects involved were Asians, the researchers highlighted the possible moderating role of culture in affecting gender behavior in online settings, such that gender communication differentiation is primarily salient in individualistic, rather than collectivistic, cultures (Lim & Lim, 2004).

Task-Technology Link

Tasks differ in terms of complexity as well as the required interaction style (Benbasat & Lim, 1993; Carabajal, La Pointe, & Gunawardena, 2003). Choice of language is influenced by the task type, as indicated by past research (e.g., Savickiet al., 1996b). McGrath (1984) proposed a circumplex that distinguishes among eight different types of task (see also McGrath & Hollingshead, 1993). The tasks vary in terms of the richness required, in which richness is defined as the extent to which a message is able to carry contextual cues, such as attitudes. The tasks, ordered in terms of increasing information richness required, are planning task, creativity task, intellective task, decision-making task, cognitive conflict task, mixed-motive task, competitive task, and performance task. In the decision-making task, there is no correct solution and group members are required to come to a consensus about the problems. In addition, more information relating to emotions and feelings is required, as compared to an intellective task that has a verifiable correct solution (McGrath & Hollingshead, 1993).

The media richness theory (MRT) (Daft & Lengel, 1986) and social presence theory (Short, Williams, & Christie, 1976) suggest that different communication modes convey different contextual cues. Past research has identified a continuum ranging from e-mail, teleconferencing, videoconferencing, to fTf meetings, where e-mail is touted as the lowest in social presence and fTf communications the richest. The underlying assumption in MRT is that when there is a "fit" between the richness of the media and the equivocality/uncertainity of the task, communication is most effective (Daft & Lengel, 1986).

However, text-based CMC does not entirely lack social contextual cues (Walther, 1992). Studies have shown that users developed an electronic paralanguage to compensate for the missing intimacy cues by encoding these contextual cues in written form (Gunawardena, 1995).

Interaction patterns are affected by the technology type (Chou, 2002); in Chou's study which examined the interaction patterns of learners, findings revealed that there were more support and personal information content in synchronous media than in asynchronous mode. In contrast, the exchanges in the asynchronous CMC constitute mainly opinion and task-oriented information.

Time

The social information processing theory suggests that relational intimacy in computer-supported groups may take a longer time to develop, despite the absence of non-verbal cues (Walther, 1996). This notion was confirmed by Walther and Burgoon (1992), who found that many of the relational dimensions of CMC groups eventually approximated those of fTf over time. Given unconstrained interaction time, high content of social-affective interaction exists in online settings (Parks & Floyd, 1996). However, when faced with perceived time limitations, either gender utilizes the expository style (e.g., flaming), thus reducing the interpersonal content in communication (Fahy, 2002). Prior empirical studies conducted in traditional environments have found time limitations and deadlines imposed to affect the behavior of group members (Druskat & Kayes, 2000).

Group Development

As a group matures, the discourse tends to shift from socio-oriented to task-oriented (Chidambaram & Bostrom, 1997). The time, interaction, and performance (TIP) theory purports that the states of the group change over time, as the group engages in more social oriented or more task oriented activities (McGrath, 1991). Group development research suggests that the initial meetings of newly formed groups are different from other meetings, as members become acquainted with one another (Chidambaram & Bostrom, 1997), whereas well-developed groups are likely to have shared norms for member well-being (Gersick & Hackman, 1990; Chidambaram & Bostrom, 1997). As a group matures, its members are likely to be able to carry out their projects, requiring "less rich information exchanges" (McGrath & Hollingshead, 1993). Newly-formed groups have fewer established norms and will perform more socially related interaction activities (Dennis & Valacich, 1999).

FUTURE TRENDS

This article has developed a framework that can be useful for understanding the discrepancy in findings of gender communication styles. The key to understanding gender differentials in discourse lies in examining situational elements, as proposed by the socio-contextual view (Strough & Covatto, 2002). Despite the importance of interaction in CMC education, there remain a large number of avenues that are yet to be explored in the arena. For instance, to what degree does each identified contextual factor influence the interaction style? How do these interaction patterns affect group dynamics? What specific patterns of interaction style contribute most to learning effectiveness? With these questions addressed, then instructional designers would be able to better incorporate suitable aspects into the design of educational software and thus help enhance online group learning outcomes.

Future researchers could also augment our framework with the social network perspective, which will lead towards a greater understanding of interaction patterns within the CMC medium.

CONCLUSION

Owing largely to the inherent intricacies of group interactions in online discussions, past research efforts have not quite satisfactorily addressed the effects of situational dimensions that will affect gender discourse in the CMC medium. This article represents an attempt to fill the gap by contributing to the knowledge of gender discourse research, with a focus on the interrelationships among learners, task-technology link, group development and time.

KEY TERMS

Asynchronous CMC: An electronic medium that enables time delayed text-based communication among parties. Examples include e-mail and computer conferencing.

Collaborative Learning: When students collaborate in groups to learn.

Constructive Learning: Describes learning as an active process in which learners interpret experiences to construct knowledge.

Group Development: The study of how groups mature over time.

Groupware: Collaborative software used to aid team work. Examples include e-mail and chat software.

Learner-Content Interaction: Results when learners examine and learn from course materials such as Web-based learning content.

Learner-Interface Interaction: Refers to how learners utilize technologies to communicate with the course content and participate in online learning activities with instructors and other learners.

Learner-Learner Interaction: Refers to interaction among learners.

Social Presence: The degree to which a medium is perceived as conveying the presence of the communicating individuals.

Synchronous CMC: An electronic medium which allows real-time interaction with others who are online simultaneously. Examples include videoconferencing and chat rooms.

INTRODUCTION

Multimediality, interactivity, and inter-connection as well as independence of place and time are potentials of e-learning and can bring about an increase in quality and flexibility of learning. E-learning comprises a variety of scenarios, which differ in their didactic approach and application of media technology. Reinmann-Rothmeier (2002) refers to a model of Back, Seufert, and Kramhöller (1998) consisting of three scenarios according to the main function of new media in the learning process. In e-learning by interacting, the new media facilitate interactions between users and the system, in e-learning by distributing, the new media function as distributors of information, and in e-learning by collaborating, the new media are applied in order to support group work. This trisection traces roughly the history of e-learning. Up until the mid 1990s, e-learning mostly consisted of programs on CD-ROMs run by learners on single PC-units. With the spreading of the Internet, the search for and distribution of information via the Web has continuously grown in importance. Currently, efforts are being made to improve interactivity and collaboration between learners and teachers to overcome the isolation of e-learners using CBT. Blended learning concepts evolved and CSCL emerged as a research field to consider technical and didactic aspects of online collaboration.

Influenced by the shift in didactics from an instructional to a constructivist paradigm, current research questions are, however preferences, skills, and demands of users can be integrated into e-learning technology. Along with this development, gender aspects have become a focus of research. In this article, we will first clarify how the co-construction between gender and technology can be understood without lapsing into dichotomous and self-reifying patterns. We will then outline the multifaceted network of gender aspects in e-learning. We aim to develop a list of demands for e-learning scenarios and will propose an approach for technical construction that takes gender and diversity demands into account.

BACKGROUND

Research on gender and ICT has identified multiple aspects that affect gender differences regarding access to and use of computers. On the individual level, attitudes and competencies concerning the application and acceptance of computers are acquired to different extents. For example, more girls and young women use computers in a rather application-oriented way, whereas more boys and young men act rather playful and oriented on programming (Feierabend & Klinger, 2003). On the structural level, there is an obvious segregation of the information technology labor-market in many European countries (Ruiz Ben, 2002), so that women rarely gain influence on new technology development. On the symbolic level, a close link between technology and masculinity still prevails in the European and Anglo-American spheres, hindering girls and women in dealing with ICT.

A closer look, however, also shows that the variation of habits, preferences, and interests of ICT-users is by far more complex and differentiated than the postulation of the “digital divide” and the “female distance to technology” suggests. Gender research has pointed out that women and men are in no way homogeneous groups. The diversity of the users of ICT has to be considered within as well as between gender groups. Referring to the keyword "co-construction of gender and technology", current approaches of gender research examine how gender is being re-constructed in the complex network of interaction between individuals and technology.

Constructive realism (see Meßmer & Schmitz, 2004) means that male or female strategies of behavior concerning the use of technology are not determined by gender or biology. They are multiple, dynamic, and flexible. Aspects such as age, ethnicity, class, education, social, and economic factors shape these strategies of behavior. They emerge, however, in a society in which gender as a structural category is embedded in every social sphere and in which it is present even in technology itself. Consequently, the affiliation to a gender group is often characterized by similar experiences. These experiences may be constructed, but they are real within one's perception and have an effect on the shaping of strategies and future behavior. Therefore user-oriented e-learning has to consider gender differences as well as the plurality of, and the mutual relations between individual, social, cultural, and technical facets.

MAIN TRUST OF THE ARTICLE

The Gendered Interactive Network of E-Learning

A gender- and diversity-oriented development of e-learning has to take all variables affecting the actual use of the technology and their interconnections into consideration: diverse learners, learning scenarios, and e-learning systems.

a. Learners differ in terms of age, gender, and ethnicity, and also in regards to their computer literacy and discipline-specific competencies. Recent analyses have shown that the digital divide in the use of the internet depends less on gender alone than on a combination of age, education, and gender. Whereas male and female members of younger and well educated groups are almost equally online, the number of female users of the internet decreases strikingly in groups of higher age and lower levels of education (Fluck & Wagner, 2003). Learners have different technical and economic resources at their disposal (e.g., computer equipment and programs), and girls and women are still likely to have inferior computer equipment than boys and men (Feierabend & Klinger, 2003). These gender differences are larger in technical and natural sciences and smaller in cultural and social studies (Middendorff, 2002).
Learners differ in their motivations, interests, and values and develop individual strategies of learning. There are many models of learning which classify learners, for example, according to the modality of sensual perception they prefer (visual, auditive, or haptic), the way they collect and process experiences (abstract or concrete), or the extent of instruction and interaction they require (e.g., field dependence). Instead of defining individual learning styles as fixed traits, current research tends to treat them as strategies, which are applied in different situations in order to fulfill different tasks. In addition, research on gender-specific learning preferences does not reveal consistent results. Yet the preference of many women to learn in groups seems to be confirmed (e.g., Leong & Hawamdeh, 1999; Frank, Kassanke, & Suhl, 2002; Rajagopal & Bojin, 2003).
The connection between learning and communication strategies is especially important for collaborative work. The prospects that virtual communication would overcome restrictions women experience in face-to-face communication were not realized. Some studies identified typically "male" competitive and "female" supportive and attenuative communication styles in huge, anonymous mailing lists (Herring, 1996). Communication processes in smaller teams, for example in doubles, via e-mail (e.g., Pohl & Michaelson, 1997) and in professional settings are much less shaped in a gender-specific way. Styles of communication generally depend very much on particular situations and are modified by the degree of anonymity and professionalism, the size of the group and their gender ratio, the frequency of contacts and the topics that are discussed (for details see Cornelius, 2002; Savicki, Lingenfelter, & Kelley, 1996).

b. "Learning scenarios" describe the didactic conception of a course or a seminar, especially the underlying learning theory, the media in use, the design and timing of learning units, the degree of virtuality and the particular demands of the addressed group and the field of study. Learning systems based on behaviorist theories consider behavior and knowledge as results of reinforcing and punishing factors. In CBT or WBT, learners repeat exercises until they are answered correctly (e.g., vocabulary coaches). Exponents of cognitivism do not regard knowledge as acquired information but as a process of understanding and digesting information. For that reason, cognitivist learning programs offer complex situations, problem-oriented mediation of knowledge and they reveal relations and contexts. Communication and cooperation between learners and an active creation of knowledge are essential for the learning process in constructivist theories of learning. Consequently, synchronous and asynchronous communication tools are applied in order to make online collaboration possible. The decision in favor of one theory of learning is a fundamental aspect of the conception of an e-learning course and depends on the learning tasks and the addressed group. Given a gender sensitive view, the preference of women for group learning is an argument in favor of intensified collaboration and blended learning concepts. However, especially women who have familial responsibilities consider the independence of place and time a very positive aspect of e-learning (Sullivan, 2001). Unlike their male counterparts, they usually subordinate time for learning with computers to family demands (Burke, 2000). This aspect should be taken into account for the design and time management of e-learning courses.
   Girls and women generally estimate their computer literacy lower than boys and men, irrespective of their actual skills (Dickhäuser, 2001; HERI, 2000). This self-estimation affects their motivation to participate in e-learning courses. In addition, demands and methods of the field of study influence the participation of women (Claus, Otto, & Schinzel, 2003).
c. E-learning systems offer a wide range of functionalities for organization (calendar, administration, etc.), for content management, and for communication (chat, forum, e-mail, white board, tools for text annotation, etc.). The systems differ not only in the functions they offer, but also in their demand for particular technical equipment and competencies from learners. They vary in the way design, navigation and demands on usability are realized and in the extent to which the learners themselves are permitted to shape the systems. Additionally, the contents and the mediatization of knowledge are of great importance: the language, metaphors, images, and examples the system uses and the manner in which knowledge is presented and connected, for example hierarchically or in semantic nets (for overview, Campbell, 1999; Schmitz & Meßmer, 2005).

The Implementation of Gender and Diversity in E-Learning: From Analysis to Construction

Alterations in e-learning have to take the multiple and interactive aspects of e-learning into consideration. At the same time they should respect gender demands. A change for the better, however, cannot occur with development of special learning methods or technical systems which are thought only for women. This would only redefine gender stereotypic behavior and role assignments. It is more important to develop didactic concepts that take the varied requirements, precognitions, media biographies, learning styles, motivations and interests of the learners into account (Schinzel, 2001).

In the last couple of years first guidelines were developed that are applicable to the different aspects of the interactive network of e-learning (see Table 1).

FUTURE TRENDS

The constructive change towards the implementation of such guidelines into e-learning technology is characterized by the realization that both the learners and the teachers are actors in the e-learning network. Feminist approaches foster the elimination of the exact division between software design-

Table 1. Examples of guidelines for gender sensitive e-learning (for details see Schinzel & Ruiz Ben, 2002)

Work organization and the curriculum:
Avoidance of gender specific division of labor (men for engineering/women for content)
Gender adequate definitions, for instance media skills that take social abilities and reflective competencies against technology into account
Forms of learning that foster co-operation and augmented creativity
Didactical methods for new media:
Contextualized content instead of abstract topics
Examples relevant to real life and personal experiences
Avoidance of specifications based on the context of men's lives (as opposed to women's): unbiased representations of gender, gender neutral language, a well-balanced selection of topics, gender independent role appropriations and unbiased gender content
Didactic based on constructive learning theories
Multimodal designs, graphic and dynamic representations, alternative forms of representation for diverse learning styles, interests and experiences
Development of sensitivity to role stereotypes, and the discussion of differences
Technical support
Technologies that are suitable for everyday use and easily manageable rather than overloaded
Facilities for users to design and shape technology
A learning environment designed for learner-centeredness, experimental and explorative learning (constructive principles)
Implementation of various possibilities of navigation
Development of technological support of group work

ers on the one hand, and software users on the other (Crutzen, 2004). When users can better customize the technological tools for their respective requirements, then the plurality of the actors and their needs can be better allowed for.

One trend is to offer tools in large e-learning platforms for all possible requirements. However, the acclimation to these huge systems frequently turns out to be very time consuming and they often require particular hardware or software equipment. Possible results are a reduction of motivation and withdrawal from the learning scenario. Alternative concepts favor modular solutions in e-learning development (Meßmer et al., 2003) where simple and intuitive user surfaces can be made available. Teachers and learners can then choose and combine only those functions they need for their particular class, (e.g., content management, e-mail, forum, or chat for communication, text editing functions for collaborative work, or tools that facilitate role distribution between learners and teachers). At the same time, users can also design the e-learning room with a few technical details (color, order of buttons, etc.). This allows for autonomous experience with the technology. The accessible functionality and interactive ease of learning can help reduce technical barriers and deficits in learners' motivation. Additionally, the modular principles keep the system open for implementing further functions with increasing computer literacy of the users or new demands during the learning procedure.

In a modular system tools can be integrated that permit different learning strategies to serve the constructive approach to learning. A current area of research focuses on the development of gender sensitive technical support for information structuring and the visualization of contextualized and complex networked knowledge content. Based on concept maps, teaching and learning environments are set up so that the learners' different strategies of knowledge acquisition can be considered. These knowledge structures must be visualized with adequate tools and must be accompanied with navigational support that is sensitive to gender and diversity. By the means of flexible and selectable navigational tools (e.g., hierarchical and/or networked navigational aids), various navigational preferences can be taken into account.

In relation to the requirements necessary for collaborative work, multi-optional means of communication with combined synchronic and asynchronous tools (e.g., collaborative text edition and text writing facilities) support study groups in conjointly discussing subject matter or in presenting results of their work together (Schmitz & Meßmer, 2005).

CONCLUSION

The contradictory results of gender differences in e-learning allows for the assumption, and even the hope that we are presently in a phase of upheaval. The discussion of gender and ICT often seems even more stereotypical as it actually turns out to be in practice. Within each gender group there is a plurality and diversity of behavioral strategies. In addition, the role of gender in exposure to and in the perception of technology and its symbolic content are constantly in transition (Wajcman, 2002). Against the background of co-construction of gender and ICT this dynamic may improve the inclusion of women in the information technologies. With a focus on e-learning this inclusion can be supported by guidelines combined with appropriate technical developments. Implementation of plurality and diversity in didactic methods and technological design, and the users opportunity to shape technology according to their own needs are challenges for a gender adequate constructive change.

KEY TERMS

Blended Learning: Type of e-learning that combines virtual phases of learning with classical activities of face-to-face learning, such as workshops, seminars, courses; also known as mixed, integrated or hybridist learning.

CBT: In Computer-Based-Training electronic programs are used to support the learning process in a dialogic manner. Texts, images, sound, video, or animations are combined. The learning software is only available for locally installation on the learner's computer. Communication via internet is not possible.

Collaborative Learning: Collaborative learning denotes learning in group work. In e-learning mediated collaboration, the focus is on the collective effort to complete all tasks that are intended for the learning process. Effective communication is a central prerequisite for effective collaboration.

Concept Maps: Concept maps structure multi-faceted knowledge based on interconnected ontologies. In XML based Topic Maps, for example, topics (keywords, themes) are linked by associations and all can refer to objects (resources, URLs).

CSCL: Computer-Supported Collaborative Learning is an interdisciplinary field with the aim to create a better understanding of collaborative learning that is mediated by computational technologies. On the basis of social, psychological, pedagogical and learning theories CSCL facilitates, develops, and analyzes group work, communication and collaboration processes, information sharing and role distribution in teams.

E-Learning: In general, e-learning denotes all learning scenarios with new media. In a more closely definition e-learning has to fulfill all of the following characteristics: (a) The use of modern multi media technology, (b) the use of a range of autonomous and interactive learning facilities, (c) individual supervision as needed and, (d) the use of electronic data and communication networks.

WBT: Web Based Training was developed from CBT. Courses in WBT are accessible via the internet and offer additional alternatives to communication and interaction between learners, teachers and tutors via e-mail, chat or forum. In WBT changes in course content can be made while the course is still taking place.

Gender and Education in Oral Traditions, Culture, and ICTs

INTRODUCTION

Seelampur, situated in the northeastern part of Delhi, the capital city of India, is characterized by low-income groups, high population density and poor civic amenities. It is a Muslim-dominated area with a high density of population and low family incomes. The average monthly family income is about 60-80 United States (U.S.) dollars, and the average family consists of eight members. Within Seelampur, the area of Zaffarabad (having approximately 90% Muslim population) stands out as a pocket of extreme urban poverty and immensely poor living conditions; open drains are clogged with sewage, power breakdowns are frequent, houses are dilapidated and people are residing in overcrowded lanes. Lack of opportunities in terms of education and employment also mark the life for people here. Formal education has become quite common, and thus, enrolment is high, but dropping out at different grades is a continuing problem. Most young women have not completed high school, as they usually drop out of the school after finishing Grade 8. Datamation Foundation initiated some work in the area, particularly with women, in 2002. At this time, UNESCO launched a pilot initiative to innovate and research social and technological strategies to put information and communication technologies (ICTs) in the hands of the poor. This seemed a good opportunity in the given context, so an ICT center was set up at Zaffarabad. The initiative seeks to deploy ICTs to address urban poverty and is designed to empower the women of Seelampur.

Figure 1.

BACKGROUND

The Cultural Settings

The towering minarets of numerous mosques in the area are indicators of the role played by religion and the clergy in the lives of the community. Traditional customs still play a powerful role, especially with respect to gender. Women are expected to be good housewives, look after their husbands and in-laws, procreate and take care of children and the house. They are not encouraged to move out of the locality independently, and the "Burqa" (veil) system is prevalent. Many other traditional practices are also still adhered to, such as with respect to kinship and arts, handicrafts and learning. It was considered that for the initiative to make inroads into the lives of the women, it may be useful for the ICT center to be located in their midst. Thus, collaboration was formed with the Babool-Uloom Madrasa. It is a Madrasa (a place of religious learning) and Masjid (the place where prayer is offered and is also the center of other religious activities) headed by the Maulana (refers to leader of prayer, Muslim caliph). The Babool-Uloom Madrasa is a religious residential school providing learning to about 200 boys from humble backgrounds. While women are not allowed entry into the mosque, they do come to the Maulana for advice. He arbitrates on social disputes and religious matters. Keeping this situation in mind, permission was sought to start the ICT center at the Madrasa, and for this purpose, space was also requested. The factor that played a positive and decisive role was not that the key people viewed ICTs as important but they felt a strong need to create some opportunities for women in the area. Indeed, it was much later that they began to understand the utility of ICTs.

The ICT center provides an open learning center for girls and women. They not only receive training on computers and the Internet, but also obtain information on varied topics. Interactive multimedia content is developed and used to support vocational and life-skills training and provide rights-based information on various areas to poor girls and women. The marginalized women use ICTs to learn marketable skills and build their awareness of health issues, their rights and livelihood opportunities. In contrast, the Madrasa has its own philosophy, where it seems to isolate itself from the outside world and the teachings have little influence of the outside, changing world. For ICTs to establish their appropriateness, an overall evaluation is necessary. In an ideal world, universal access to information would create a global information society, yet the mode of interpretation will depend on the culture and traditions of the people and societies. Yet, the endeavor in community-based interventions has been sensitive to cultural differences, which was also the point of departure for the present initiative. The decision to set up the ICT centre in the annex (one room) of the Madrasa gave it immediate legitimacy. Appreciating the socio-cultural scenario and the importance of the Masjid and Maulana in the lives of the community helped to harmonize that with the technological tools.

In today's information age of globalization, computerization, the Internet and the virtual world, there are fears that the global media is fast promoting a global monoculture that denies diverse socio-cultural realities. It is felt that this process of globalization may swamp the not-so-strong cultures. English is the predominant language of the information age. The majority of material on the Internet is from developed and industrialized countries. Thus, there are fears that local cultures would be eroded, so the tendency is to further isolate themselves. The global village is not global for most of the world's poor, not simply because technology is not available to them, but because with or without these technologies the poor are likely to remain marginalized from the benefits of society if they are excluded from the benefits of overall development. Apart from this is the issue of language and content, because of which even if computers may be physically available they may continue to be "out of reach" in crucial ways. Thus, the intervention was located within this fraught relationship between the modern-global and the traditional. There is an interesting contrast between the possibilities of globalized culture that the computer/Internet represents while being at a place that fiercely protects the local culture. What have been the experiences?

HOW THE ICT INTERVENTION HAS ADAPTED TO CULTURAL VALUES

It was felt necessary to embed the project in the community, taking into account existing cultural values. Concrete actions are being taken to preserve the local oral culture and propagate the same. For culture to grow, it must be active, contextual and social. ICTs, such as videos, TV and multi-media computer software that combine text, sound and colorful images, are used to provide media for expression, acting as facilitator. The Ethnographic Action Research (EAR) revealed that women spend a considerable time at home watching soap operas and Hindi movies on television. Seeing the glamorous people on screen, they too are keen to dress well and dance and sing like them. They are also keen to act. The ICT center provided them a platform and an opportunity to express their talents. At the Madrasa, singing is taboo. So the girls sing "Naaths" (odes to God), with their heads covered in reverence. These along with stories, comic skits and plays have been recorded at the ICT center. Technological skills have been acquired in the process of expressing talents. Digital photography, downloading on the computer, sound recording are some of the skills learned in the process. Elderly women are being encouraged to record old songs, lullabies, recipes and home-remedies for illnesses. This initiative is named “Seelampur Voice.” CD-based programs of this nature are cablecast for wider viewing by the community. The endeavor is not only to preserve the local culture by recording, but also to encourage others to come forward to share their experiences, talent and learning acquired through their elders. The learning of local art and handicraft is being encouraged in the process of learning computers. The girls bring local traditional designs and patterns of embroidery to the center. These are computerized through the process of scanning or digital photography. Then these pictures are modified and improved, and more innovative designs are developed with various color combinations. Some of the participants download various patterns from the Internet and then evolve their own designs using traditional and modern tools as a base. It is the same with the application of intricate Mehendi patterns, traditionally made on the hands and feet of women. These designs, which are created, are transferred on various products (Indian handicrafts) and are taken to different exhibitions all over the country. Sale through these exhibitions and from the center itself has enabled the participants to generate about Rs. 50,000 in the year 2004-’05. Seeing the encouraging response at these exhibitions, the Foundation undertook an e-commerce endeavor, wherein a portal (www.seelampurmart.org) was set up in November 2004. The Web site provides a platform for buyer-seller/producer interaction, business transactions and e-commerce.

The Internet in conjunction with eNRICH, a local Web-based browser, is being used imaginatively to record and showcase local talent and cultural heritage. At the same time, the participants are getting exposure to other cultures and ideas. Thus, computers and the Internet create the possibility for such mutual sharing and learning. E-mail has opened an avenue to have exchanges with people of the same religion living in different countries. Images from the Internet coupled with e-mail exchanges are making participants aware of the cultural differences and similarities among Muslims living in countries like Malaysia, Bangladesh, Pakistan, West-Asia and the West. Looking at cultural aspects with a sense of enquiry and respect has been a big gain from the ICTs. Hindi and Urdu are used along with English to facilitate learning. Some computer-based learning programs in the form of vocational CDs have been developed, with voiceovers and content in Hindi as well as English. This was done for easy comprehension and for the realization of the importance of English as a link language (especially for using the Internet). Above all, there is an informality of atmosphere so that the staff and project team members are open to approach.

Studies have shown that despite its criticality to the success of information technology projects, culture is the most difficult to isolate, define and measure. From the conclusions of the studies, every country must have an information technology policy that recognizes its culture and ensures that adoption of information technology does not destroy the cultural heritage. The problem arises when there is a difference between the “culture of an IT product and the culture of its users.” Hence, every possible effort has been taken to develop local content in Seelampur. It was observed that girls were keen to acquire certain vocational skills while learning to handle computers. To fulfil this need, CD-based vocational skills learning packages were developed in-house, where participants have been actively involved. The packages, with a voice-over option in both English and Hindi, include candle making, liquid soap and phenyl making, henna application and designs, making of soft toys and rag dolls, tailoring and so forth, and are based on their traditional skills (such as handicrafts). Many new avenues are being explored to make these girls have a means for an independent income. Many of the girls eagerly desire to have an independent source of income after coming to the center and to be able to support or help their families financially.

Right from the start (April 2003), the computer center is seeing the participation of more than 100 girls each month, who come there both for computer and vocational skills learning. The tutor at the center is from the same community, so the girls feel comfortable. Sensitivity has also been shown, in that the girls from the community are not allowed to move unaccompanied, especially outside the confines of Seelampur. Consequently, in any event, such as the WSIS meeting or the Knowledge Fair at Global Development Network meet, or for the trip to Agra city that adjoins Delhi, adequate travel arrangements were made and it was ensured that the girls were escorted to and from. Thus, they were not denied the opportunity for the exposure because of these mobility restrictions.

HOW THE COMMUNITY AND THE CLERGY HAVE ALSO ADAPTED

There are the traditional restrictions on mobility. Added to this is the fear of the "anti-social" elements that prohibit parents and husbands in Seelampur from sending women from their homes outside Seelampur. Sexual harassment of girls is quite common in the area, and one hears of such cases frequently. The Community ICT Center has gradually emerged as a "nodal" point of social contact in Seelampur, as this is perceived as a safe place. Many women state that they feel very happy coming here and want to stay here for longer periods. Some women have profusely thanked the team at the center for providing them an opportunity to "constructively" interact and socialize. Now, older women and men in these families also support them in this interest. Several opportunities have been created, such as picnics and other visits, to facilitate their mobility even outside the area.

The center is on the first floor of the annex to the Madrasa, with an independent entry from the lane. The girls were allowed to enter the Madrasa from a side entrance, go up to the second floor, transit through the dormitory being used by the boys and then cross over to the annex. The girls were apprehensive of the arrangements, especially of going through the dormitory, but the arrangement worked. Though girls are not allowed into the Masjid, they were permitted to transit through the exclusively boys' zone in this instance.

FUTURE TRENDS

There is Resistance to ICT-Enabled Education

There are occasions when traditional values are too strong and play a decisive role. In such situations, the women may raise a voice or submit to tradition. The center was formally inaugurated by the Chief Minister of Delhi on June 26, 2003. The girls were enthusiastic and so were guided to organize the center, make arrangements to receive the honorable guest and present themselves appropriately. The Maulana was the chief coordinator. It had been planned that after the formal inauguration of the center, the Chief Minister would be escorted to a hall that serves as the Madrasa as also the Masjid, where she was to be felicitated publicly. After that she was to address the gathering. Yet, despite their efforts because of tradition, the girls were not permitted entry into the hall. Often within the kinship context, age-old patriarchal values may reinforce themselves, even if by raking new forms in the face of these changes. Recently in Seelampur, girls are being rejected in the process of spouse selection in arranged marriages on the grounds that they know computers so they will not "adjust" in their marital family. Similar instances have also come to light about the boy's kin making greater demands for dowry from the girl's family if she is computer literate. Voices are raised in dissent.

The girls remain in awe of the Maulana because of his status and traditional standing. During the month of Ramadan, he wanted the centre to be closed down. All through the month of Ramadan devout Muslims keep strict fast. Only before sunrise and after sunset do they take food. In early morning, as the call for prayer is heard from the mosques, the boys and men set off to offer Namaz (prayers). Women stay at home and recite the "Quran." Fasting during the days of Ramadan normally does not affect their daily routine and they go on with their daily chores. Thus, the 29 or 30 days of the month of Ramadan pass and the sighting of the new moon brings glad tidings of Eid-ul-Fitr and the end of the month. The girls were not happy with the decision that the center be closed down for the month of Ramadan. They were enjoying the learning experience at the center. They were encouraged by the project staff to go through the relevant Web sites to understand the significance and meaning behind the rituals and why Ramadan is observed. Having understood, they gathered courage and went to the Maulana to plead their case to keep the center functioning. They did that convincingly and successfully. The compromise arrived at was that the center would close down at 4 p.m. instead of at the usual 5 p.m. Only a few months ago, such a dialog between the Maulana and the girls would have been unthinkable.

Despite remarkable achievements, it would not be out of place to mention that the project of this nature cannot succeed if the enabling technologies and environment are not supported by enabling role models. The ICT project certainly requires technical support and infrastructure in terms of trained people, assured power supply, phone lines and a suitable environment. Importantly, the project leverages on the skills and competence of the local women, by channeling these into income-generation opportunities. With the help of Tele-Centre income, sales proceeds of the SHGs selling their arts and crafts apart from the fee paid by the women (very nominal); the project is sustainable. Many examples of increased confidence, as the center provides women an opportunity to socialize and be creative and search for information and learn new skills, make the center unique and desirable. For the project to be sustainable in the long run, there is a need for careful monitoring, ensuring that the situations of the marginalized and vulnerable are not worsened unintentionally. This monitoring system is in place, which would ensure sustainable benefits and outcomes. A revenue model for the project has also been set up, wherein the buyer who gets linked with the women producers of products and services pays the Foundation a fixed amount per annum as a transaction fee for merchandising with the women. These sources of income will ensure continuing sustainability of the project, as the buyer of embroidery products made by the women of Seelampur will pay a fixed royalty to the Seelampur Community ICT Center.

CONCLUSION

These small steps lead to changing relationships and practices and adapting of old values to new situations. The project has provided an opportunity to participants to interact with the external world and come in direct contact with the ultimate buyers of their products. Development of innovative and interactive multimedia packages to support vocational and life-skills training and provide rights-based information to women has been one of the satisfying and useful activities of the project. The action researchers have been increasingly involved in providing vocational training to women visiting the center. Through the project, about 1,000 women have been computer trained. Greater faith in the capacity of girls and the need to educate them has been generated. As we go along, these seemingly small changes may go on to impact the culture. Culture is how we view events, how we think, how we perceive events, and how we react and respond. Culture consists of social norms, group behavior, respect and authority of decision makers. This experience shows that while every effort is being made to respect the local culture, the project is also impinging on the participants and the stakeholders, making them think and act a little differently. Earlier, there were doubts as to whether the space would continue to be provided by the Madrasa or the center would have to shift. The outcomes are very evident in the fact that now there is a commitment to give the space for the center for many years to come, and an extra room has also been provided for the center. The initiative has shown that ICTs can be utilized to understand, preserve and share cultural heritage apart from enhancing cultural values. Local culture can be shared with people of different cultures with mutual understanding and respect. The exposure builds confidence in the women, and they are able to articulate their opinions better. The Seelampur Community ICT center initiative has been an interesting learning experience for the community as well as for the project ream.

KEY TERMS

Burqa: A loose garment (usually with veiled holes for the eyes) worn by Muslim women especially in India and Pakistan.

Eid-ul-Fitr: A festival that ends the fast of Ramadan.

Imam: The Muslim worshiper who leads the recitation of prayer when two or more worshipers are present.

Madrasa: A building or group of buildings used for teaching Islamic theology and religious law, typically including a mosque.

Masjid: The place where prayer is offered; also the center of other religious activities.

Maulana: Refers to the leader of prayer, Muslim caliph.

Mosque: A Muslim house of worship.

Naath: Odes to god.

Ramadan: The ninth month of the year in the Islamic calendar is the month of Ramadan. During this time a fast is held from sunrise to sunset.

Gender and End-User Computing

Laura Beckwith

INTRODUCTION

Although gender differences in a technological world are receiving significant research attention, much of the research and practice has aimed at how society and education can impact the successes and retention of female computer science professionals. The possibility of gender issues *within software*, however, has received almost no attention, nor has the population of female end users. However, there is relevant foundational research suggesting that gender-related factors within a software environment that supports end-user computing may have a strong impact on how effective male and female end users can be in that environment. Thus, in this article, we summarize *theory-establishing* results from other domains that point toward the formation of grounded hypotheses for studying gender differences in end-user computing.

There has been much background research relevant to human issues of *end-user computing*, which we define here as problem-solving using computer software, also termed *end-user programming* in some of the literature (e.g., Blackwell, 2002; Green & Petre, 1996; Nardi, 1993). (See the glossary for definitions of these and related terms.) Despite this, few researchers have considered potential *gender HCI issues* and gender differences that may need to be accounted for in designing end-user computing environments. The most notable exception is Czerwinski's pioneering research on the support of both genders in navigating through 3-D environments (Czerwinski, Tan, & Robertson, 2002; Tan, Czerwinski, & Robertson, 2003). Although individual differences, such as experience, cognitive style, and spatial ability, are likely to vary more than differences between gender groups, evidence from Czerwinski's work as well as work in other domains, such as psychology and marketing, has found gender differences relevant to computer usage. In fact, some research has shown that some software is (unintentionally) designed for males (Huff, 2002).

One reason gender HCI issues in end-user computing are important is that ignorance of gender issues has already proven to be dangerous: today's low percentage of computer science females (Camp, 1997) has been directly attributed to the past unawareness of gender issues in computer science education and in the workforce. There is a risk that if gender HCI issues in end-user computing environments are ignored, a similar phenomenon could occur with female end users.

WHAT COULD GO WRONG?

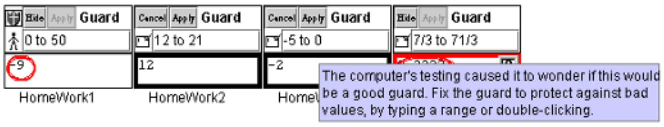
What gender differences might matter in the design of end-user computing environments? Consider the following scenario in one particular end-user computing environment.

Imagine a female teacher engaged in preparing a spreadsheet to track her students' scores and to calculate ways of providing students with the best grades. Part of her process of preparing her spreadsheet is to test the spreadsheet. While she is engaged in testing, the system surprises her by decorating some of the spreadsheet cells, as in Figure 1.

The surprises were intentionally placed into the software by the designers relying on a strategy for

G

Figure 1. A spreadsheet calculating the average of three homework scores. Assertions about the ranges and values are shown above each cells' value. For example, on HomeWork1 there is a user-entered assertion (noted by the stick figure) of 0 to 50. The other three cells have assertions "guessed" by the Surprise-Explain-Reward strategy. Since the value in HomeWork1 is outside of the range of the assertion, a red circle notifies the user of the violation. A tooltip (lower right) shows the explanation for one of the guessed assertions.



end-user computing environments called *Surprise-Explain-Reward* (Wilson et al., 2003). The surprise, which was intended to capture the teacher's attention and arouse her curiosity, reveals the presence of an "information gap" (Lowenstein, 1994). In this case the system is using the surprise to interest her in assertions (Burnett et al., 2003), which she can use to guard against future errors by specifying, for example, that the value of a cell calculating a grade average should always fall between 0 and 100.

What could go wrong in surprising the user? According to Lowenstein's information gap theory, a user needs to have a certain level of confidence in order to reach a useful level of curiosity (Lowenstein, 1994). However, given documented gender differences in computer confidence (Busch, 1995; Huff, 2002), the teacher's level of computer confidence could interfere with the surprise's ability to capture her interest.

Returning to our scenario, suppose for this particular user, the surprise is effective at arousing her curiosity, she looks to the object that surprised her (the assertion) for an explanation. The explanation, viewed through a tooltip, includes the semantics, possible actions she can take (regarding the assertion), and the future reward(s) of taking the action. See Figure 1.

What could go wrong with the explanation? According to one theory, males and females process information differently (Meyers & Sternthal, 1991; O'Donnell & Johnson, 2001), and thus both the presentation and the content of the explanation may impact its effectiveness for males versus females. If the information needed by the user is not effectively communicated, the user's ability to problem solve is likely to be reduced.

Another role of the explanation is to help users make a reasonably accurate assessment of the risk in taking some action—but since males and females differ in their perceptions of risk (Byrnes, Miller, & Schafer, 1999), the explanation may need to serve these two populations differently in this respect as well. (An example of risk may be the fear that the user will lose their work if they try a certain feature.) If one gender perceives an explanation of a feature as communicating higher levels of risk than another, the users with higher risk perceptions may avoid supposedly "risky" features that may be important to overall effectiveness.

Perhaps the most important role of explanations is to make clear the rewards of using particular features of the software. Providing information about rewards in the explanation is consistent with the implications of the Model of Attention Investment (Blackwell, 2002), an analytic model of user problem-solving behavior that models the costs, benefits, and risks users weigh in deciding how to complete a task. An implication of this model is that if the system provides the user an idea of future benefits, users can better assess if the cost of using a feature (here assertions) is worth their time. The reward aspect of the strategy refers to rewards such as the automatic detection of errors, which is depicted by the red circle around HomeWork1's erroneous value in Figure 1.

What could go wrong with rewards? Since males and females are often motivated by different factors, there may be gender differences in what actually is a perceived "reward." If the rewards are only tailored to one gender's perceptions of rewards, the other gender may not be motivated to use the devices that will help them be effective.

In this end-user computing scenario, potential problems arose *that may be addressable within the end-user computing software itself*. Four issues that arose here were (1) software features whose effects depend upon users' computer confidence (discussed in the section on *confidence*), (2) the software's ability to communicate effectively with users (discussed in *support*), (3) the possibility of a user's perception of risk interfering with the user choosing to use appropriate features (discussed in *confidence*), and (4) possible differences between a user's actual motivations and the software's attempt to "reward" users for using particular features (discussed in *motivation*). These issues together form a useful organizational framework for considering gender HCI.

CONFIDENCE

This document uses the term "confidence" for the interrelated concepts of self-confidence, self-efficacy, overconfidence, and perceived risk.

From the field of computer science, there is substantial evidence of low confidence levels as computer science females compare themselves to the males (Margolis, Fisher, & Miller, 1999). Of particular pertinence to end-user computing, however, is the evidence showing that low confidence relating to technology is not confined to computer science females (Busch, 1995; Huff, 2002; Torkzadeh & Van, 2002).

As a measure of confidence, researchers often use self-efficacy, as was done in the Busch study. *Self-efficacy* is belief in one's capabilities to perform a certain task (Bandura, 1994). There is specific evidence that low self-efficacy impacts attitudes toward a new software package prior to its use (Hartzel, 2003). Taken together, this research suggests that a first experience with end-user computing software can impact attitudes which may in turn impact users' future choices to (or not to) use some features in their software.

Overconfidence matters too, because it can prevent people from suspecting errors, leading to misplaced trust in erroneous programs. In particular, overconfidence in spreadsheet correctness is common (Panko, 1998). There is evidence (Lunderberg, Fox, & Punchochar, 1994) suggesting gender differences in overconfidence just as in under confidence. Hence, designing methods to help alleviate overconfidence in end-user computing needs to be carefully targeted specifically toward overconfident users.

Perception of risk is tied to confidence, and impacts the decisions people make. According to the attention investment model (a model of how users allocate their attention in problem solving) (Blackwell, 2002), a user may choose not to follow through a particular action, if they decide that the costs and/or risks are too high in relation to the benefits of taking that action. Perception of risk thus plays an important role in a user's decision-making about whether to use some features, and can lead to differences in actual behavior.

Differences in perception of risk have been tied to gender. For example, a meta-analysis of 150 studies on gender and risk taking found that females engaged in less risk taking than males (Byrnes, Miller, & Schafer 1999). The meta-analysis did not address risks of computer use directly. However, it did find that intellectual risk taking, defined as activities involving mathematical or spatial reasoning skills, was greater in males than in females (Byrnes, Miller, & Schafer 1999).

To obtain evidence about whether confidence might directly impact gender HCI issues for end-user computing environments, we conducted a preliminary think-aloud study in which participants attempted to debug two spreadsheets, given the support of Surprise-Explain-Reward devices (Beckwith & Burnett, 2004). To our surprise, the females' confidence levels dropped *over the course of the study* much more than did the males' confidence levels. This result suggests that end-user computing environment itself—which, like other end-user computing environments, was designed without knowledge of gender-related HCI principles—is not currently serving the females' needs as well as the males'. A subsequent follow-up study (Beckwith et al., 2005) confirmed this: in the spreadsheet paradigm, ties were found between females' confidence issues and low utilization of features aimed to support problem solving, resulting in effectiveness problems.

G

SUPPORT

We will use the term "support" to mean built-in aspects of the software, such as on-line help systems and Figure 1's tooltips that help users learn or understand the environment.

The system's approach to help users achieve mastery in remembering the software's devices may depend on a user's learning style. One survey of university students found that students with an "abstract random" learning style were significantly more likely to be female and, as a result, could find computer-based instruction ineffective for learning (Ames, 2003). Other researchers have also found gender differences in learning styles (Heffler, 2001; Severiens & ten Dam, 1997). One implication of these findings is that end-user computing may need to support several learning styles, especially if some users are easily dissuaded by support devices not sensitive to their learning style.

Problem-solving style also shows gender differences, at least for computer games (Kafai, 1998). Researchers found that, unlike boys, rather than working in a linear fashion through the game, girls prefer to explore and move freely about a game (Gorriz & Medina, 2000). In another difference in problem-solving style, boys' games typically depend upon competition, whereas girls prefer collaboration and working together (Kafai, 1998). For end-user computing environments, these problem-solving differences suggest differences in the support provided by the system. For example, supporting both linear and non-linear problem-solving styles and providing avenues for both competition and collaboration may be important for software's success at supporting both genders adequately.

Finally, the theory of selectivity suggests gender differences which may impact how users process the information support devices provide. The theory of selectivity, from research in the area of marketing, states that males and females differ in their information processing strategies (Meyers & Sternthal, 1991; O'Donnell & Johnson, 2001). According to this theory of selectivity, females are more likely to employ elaborative information processing strategies, regardless of whether the task is simple or complex in nature. Males, however, are more likely to select heuristic processing strategies that minimize cognitive effort and reduce information load for simple tasks, switching to an elaborative strategy only on more complex tasks.

These gender differences have been shown to impact diverse software-related activities, ranging from users' perceptions of Web sites used for e-commerce (Simon, 2001) to users' performance on auditing tasks (O'Donnell & Johnson, 2001). For end-user computing environments, this research may have implications for informing end users of important information via the software's support devices.

MOTIVATION

Research has shown that computer science females are motivated by how technology can help other people, whereas males tend to enjoy technology for its own sake (Margolis, Fisher, & Miller, 1999). These differences are also found with other females who use technology, such as architects, NASA scientists, and filmmakers. One study (Brunner, Bennett, & Honey, 1998) found that females described technological objects as tools to help integrate personal and professional lives and to facilitate creativity and communication, whereas males described them as technological devices to increase command and control over nature and one another. The gender differences found in that study are summarized in Table 1.

The technology acceptance model (TAM) (Morris & Dillon, 1997; Venkatesh & Morris, 2000) provides a model of users' acceptance and usage behavior of technology. According to TAM, user acceptance, and ultimately technology use, is determined by two key beliefs: perceived usefulness and perceived ease of use (Venkatesh & Morris, 2000). "Perceived usefulness" is the degree to which a user believes that using the system will enhance their performance, and "perceived ease of use" is the degree to which the user believes that using the system will be free of effort. According to one study, the relative importance of each differs by gender (Venkatesh & Morris, 2000); women were more influenced by perceived ease of use whereas men were more influenced by perceived usefulness.

Table 1. Summary of gender differences in fantasizing about technology (Brunner, Bennett, & Honey, 1998). Reprinted with permission.

	Women ...	Men ...
1	fantasize about it as a **MEDIUM**	fantasize about it as a**PRODUCT**
2	see it as a **TOOL**	see it as a **WEAPON**
3	want to use it for **COMMUNICATION**	want to use it for **CONTROL**
4	are impressed with its potential for **CREATION**	are impressed with its potential for **POWER**
5	see it as **EXPRESSIVE**	see it as**INSTRUMENTAL**
6	ask it for **FLEXIBILITY**	ask it for **SPEED**
7	are concerned with its **EFFECTIVENESS**	are concerned with its **EFFICIENCY**
8	like its ability to facilitate **SHARING**	like its ability to facilitate **AUTONOMY**
9	are concerned with **INTEGRATING it** into their personal lives	are intent on **CONSUMING** it
10	talk about wanting to **EXPLORE** worlds	talk about using it to **EXPLOIT** resources and potentialities
11	are **EMPOWERED** by it	want **TRANSCENDENCE**

FUTURE TRENDS AND CONCLUSION

To date, there has been little research on how the design of software itself may interact with gender differences. Still, foundational work from several domains strongly suggests that such differences may have critical impacts on users' success in end-user computing.

Although research is beginning to emerge providing some insights into gender's importance in end-user computing environments, it is still largely an open question. Also open are questions of what specific types of differences matter in such environments and what amelioration strategies are possible.

To help provide a foundation upon which researchers interested in these issues can build, this article has drawn from five domains to summarize literature relevant to these questions. All of the literature surveyed identifies one or more issues that potentially impact end users' success that are also potentially addressable *within* the software systems. Together, the open questions and survey are intended to provide a foundation for future investigation.

KEY TERMS

End User: Users who are not trained programmers.

End-User Computing: Computer-supported problem solving by end users, using systems such as spreadsheets, multimedia authoring tools, and graphical languages for demonstrating the desired behavior.

End-User Programming: A term synonymous with end-user computing.

Gender HCI: Human-computer interaction (HCI) work that takes gender differences into account.

Overconfidence: Higher self-efficacy than is warranted by a user's abilities.

Self-Efficacy: Belief in one's capabilities to perform a certain task.

Under Confidence: Lower self-efficacy than is warranted by a user's abilities.

Gender and E-Service in CEE and the CIS

Emma von Essen
Uppsala University, Sweden

INTRODUCTION

Information and communication technology is used today as a tool for reducing all kinds of poverty, promoting good governance, and facilitating sustainable human development. NGOs and other practitioners call this ICTD. One example of ICTD is to use different software, e-services, to promote good governance, business and reduce income and non-income poverty. However, there is a risk of ICT imposing new divides. The gender digital divide is a severe and increasing problem. The gender digital divide is the problem of ICTs, regardless of regional variations, affecting men and women differently. Women in most regions face barriers in benefiting from the development of ICT.

During the past few years, the ICT and gender movement and research on the topic has grown globally, but in Central and Eastern Europe (CEE) and the Commonwealth of Independent States (CIS) it has remained weak and without recognition (Simerska & Fialova, 2004). It is important to ask whether women in CEE and the CIS are using the new services and what roles women play within the growing e-service in business and governance in the region. This article describes the situation on women and ICTs in the CEE and CIS and will additionally highlight the potential of ICTs in promoting gender equality.

BACKGROUND

The use of ICTs is becoming increasingly inevitable, and a necessary part of everyday life. More widespread and more affordable than ever this propensity is expected to increase in the future. Researchers such as Pippa Norris have analysed and described the impact of ICT and the importance it has in societies. Norris points out that ICT and e-service applications creates new economic and social opportunities all over the world (Norris, 2001). The report of the Digital Opportunity Initiative exemplifies this by pointing out e-service applications as an important enabler of economic development (Accenture, 2001). These changes however, do not reach or benefit all sectors of society equally. This is the digital divide. Action lines from the 2003 World Summit on the Information Society highlighted that national and international political action must be taken in order for ICT to reduce traditional barriers in society and provide an opportunity for everyone to access local and global markets (WSIS, 2003).

Research by Hafkin (2003), and Huyer and Sikoska (2003), among others, show that, regardless of regional variations, the development of new e-services can affect men and women differently, creating what is known as the gender digital divide. However, they also highlight that ICT can be an important enabler of women's participation and empowerment. Huyer state that if ICT is to become an important enabler for women in the CEE and CIS there is need of promoting political action (Huyer, 2003). Huyer (2003) therefore concludes that ICTs can have a positive impact on gender equality, however, they can sustain or exacerbate inequalities if targeted actions (including policies, regulations, projects, and initiatives) are not taken.

Girard and Ó Siochru (2003) conclude in their research that, since ICT applications alone are unlikely to make a positive contribution to gender equality, there is a need for actions that promote gender issues with ICT applications. This is crucial in the CEE and CIS region because in several countries in region women are totally excluded from ICTs. (Simerska & Fiavola, 2004) These imbalances between men's and women's participation in ICTs can be found in several areas. Such as for example access to, education, decision-making, and content.

RESEARCH AND DATA

Little research has been done in the CEE and the CIS region in the field of gender and ICTs. The most recent UN-report, by Simerska and Fialova (2004) indicate that women use and benefit less from ICT applications such as e-services than men. Except for that report, most surveys in the region are carried out by private companies as market surveys for business purposes. However, these reports are just indications and they advocate for deeper research. One of the main problems is the shortage of gender disaggregated official data to measure the extent of which women are using or being supported by e-services. Few countries in the CEE and the CIS region have access to, create data, or undertake field research, which is a problem that needs to be addressed. Despite the International Telecommunication Union (ITU) recognizing this problem at a meeting in Geneva in June 2003, country specific gender data is still not available. A problem with the available data is the lack of standard definitions. Due to this, most research and data discussed in this article are on ICTs in general, not on e-services specifically. Another problem concerning research is that perceptions of women in the region have not been well documented (Hafkin, 2003). Furthermore, the lack of disaggregated data, the lack of standard definitions and the lack of documented perceptions of women results in little fact-based evidence to support and explain the indications of imbalances between men and women that are reported.

ACCESS AND EDUCATION

According to ITU, the number of telephone subscribers has increased from 14.1 per 100 inhabitants to 44.1 per 100 inhabitants in the CEE and CIS region (WSIS, 2003). Over the past three years, the use of Internet has grown by 117.5 % in the CEE and CIS.[1] These figures indicate that the use of communication channels as Internet and Mobile phones will increase in the future. The possibilities of accessing new ICTs are rapidly increasing globally and regionally, these possibilities should be shared equally. International reports show a different picture, women have less access to ICTs than men (Scott, 2003, Simerska & Fiavola, 2004).

Even if you have access to ICT, you need to know how to use it. Hafkin and Taggart describes education as an important factor in raising the use of ICTs among women (2001). However, women's tertiary education in ICTs in the region constitutes a tangible disturbing issue. Figures from ITU (WSIS, 2003) show that in the new member states of the European Union,[2] 83% of men and 13% of women participate in ICT related tertiary education. Indications from small surveys done in a few CIS countries also signal these kinds of inequalities. These surveys further show that this is one explanation to why women use Internet significantly less then men (Scott, Singh, & Wanasundera, 2001; Hafkin & Taggart, 2001). Hafkin and Tagart (2001) conclude that these inequalities are severe and actions to promote and encourage women to consider a career in ICT must therfore be taken. The rapid growth of and the education inequalities in ICTs highlights the need for immediate actions to ensure equality in both access to and education in these services. Otherwise the gender digital divide might increase.

DECISION MAKING AND CONTENT

In both the public and the private sphere, the main problem is not only women's access to and education in ICTs, but also the structural exclusion of women from the creation and innovation processes of new e-services and decision-making processes. Hafkin (2003) points out an interesting note; there seems to be no correlation between the percentage of female internet users and women's empowerment. The lack of correlation between women's use of Internet and expected empowerment indicators support the hypothesis that most women that use the Internet are not representative of women in the country as a whole, they represent a small elite (Hafkin & Taggart, 2001, p. 15). It also show that if a country only focus on access they will not automatically raise women's empowerment. This indicates that access is not the only problem concerning women's use of ICTs.

As e-services are becoming more and more important as tools integrated in all parts of society, ICT skills in power and decision-making positions are important. Every leader has special competences and skills, but basic ICT competences are becoming and have to become essential knowledge for them all. In the business sector these skills are already a necessity and a requirement. The public sphere is moving quickly towards a similar situation with e-democracy (Masters, Macintosh, & Smith, 2003; Norris, 2003). The UNECE report on women as entrepreneurs show that women in decision-making positions are far less represented then men in both public and private sectors in the region. Social structures and labour market polices reflect the traditional male breadwinner model at macro and micro levels. Women are, for example, encouraged to leave the labour market in Czech Republic and Poland through early retirement policies, and in Belarus and Ukraine through more attractive parental leave schemes (UNECE, 2002). This also shows the exclusion of women from the decision-making processes of how to use ICTs within business and governance. Since women in decision-making positions are less represented and few women have the opportunity to obtain ICT skills there will be less opportunities for women to get a job. Women will also have less opportunities to effect the purpose for what new e-services are being used.

When launching initiatives, as new e-services, concerning the issue of gender inequalities, it is important to relate the content to its' political, socio-economic and cultural context in which they are immersed into account. Public and private initiatives might otherwise sustain region specific problems. (Beneria, 2003). In the public sector, governments in the region have been focusing on providing better and more affordable services, highlighted by Hafkin and Jorge (2002) as well as others. Governments can increase access to public information and programmes through these e-services and widen the spectra of services because of increasing productivity and streamlining. Through e-services the public sector can reform and facilitate an integrated participatory approach to development and decentralization. This is a part of e-democracy. Few of these applications are used to address the primary concerns of women. The end user perspective is very important in order for these services to be utilized and useful; initiatives with a content relating to the work of women in the region would reach out to more potential "buyers/users" of the services and would make them more successful (Primo, 2003; UNECE, 2002). The UNECE report further highlights that when projects and initiatives to promote women as leaders are launched, ICTs are rarely taken into account as a factor and as a promoter. Public and private driven e-service applications should, however, be used to help women change their positions and promote women in decision-making positions. The lack of e-services in women-leader initiatives and the lack of ICT content relating to concerns of women in the region are additional arguments for political leaders to act.

Research and science are important factors concerning how ICTs could be used in the future. Women in several countries of the region are also excluded from science and technology research. Huyer and Sikoska (2003) show that this indicates that women are not integrated in the creating, maintaining or control of new e-service tools and their content. This is one of the reasons, according to Huyer and Sikoska, why new e-service applications do not provide services that address women's needs. Initiatives both by private and public sector, concerning emerging e-service projects in the region, are rarely taking gender content into account. The lack of women in science and technology research therefore also has a negative impact on the opportunities for women to enter decision-making positions. Being excluded from the creation and control processes prevents women from finding their role within the e-service development.

FUTURE TRENDS

In most countries in the region, infrastructure and policies concerning ICTs are now being laid out together with the help of donors and NGOs. Most governments in the region do not consider gender important or are not aware of the benefits of taking gender into account when dealing with ICT structures and policies[3] (Simerska & Fialova, 2004). In Hafkin and Jorge's article in 2002 they point out that if gender is not being considered when policies and structures are being laid out the opportunities to change the social context and structures might get even worse. It is therefore important for these governments to understand the benefits of including women when forming ICT policies and structures. This could increase the use of ICT among women. According to another researcher, Ramilo and Pi (2001), governments should create incitements, through policies, for private and public sector in order to get more women to use and create e-services. NGOs, donors, international- and bi-lateral organizations assisting governments in creating these policies and infrastructures have a responsibility and possibility to advocate and create incitaments for the inclusion of gender and to raise awareness (Simerska & Fialova, 2004). This is an indication that ICTs also could become an important factor for governments relating to achieve and monitor the United Nations Millennium Development Goals (MDGs).

One example where practitioners promote women in ICT is USAID's principal program in Washington for promoting ICT for development, dot-com (www.dot-com-alliance.org). In promoting policy and regulation reforms for sustainable ICT policies, dot-com advocate in an article (Trish, 2005) for the participation of women as a marginalized group. Including marginalized groups when creating new e-services is according to them an important factor of sustainability in the ICT development (Trish, 2005). Based on dot-com experiences in forming ICT policies governments should act while forming new structures, laws, and policies that will have a long-term effect.

Important tasks in the future concern political action in the fields of education, access, decision-making, and science potentially through the use of regulations and policies. Governments in the region also need to start the process of creating disaggregated data by gender to support future academic research. There is a clear demand of further and deeper research especially concerning the topic of new e-service applications and women leaders. Research can also provide a tool for advocacy for increased political actions in the region and outside.

CONCLUSION

The e-services used as tools in everyday life increase social and economic opportunities for women and men. The development of new e-services, (i.e., new opportunites), are increasing. Given the low percentage of women in ICT related education, in decision-making positions and in science combined with the growing importance of e-service applications there is a huge risk of sustaining or exacerbating the old gender inequality structures. E-services are not gender blind tools, they are strongly connected with the political, social and economic structures in which they are created and used.

In the region of Central and Eastern Europe and the Commonwealth of Independent States the foundations in terms of infrastructure and policies are now being formed. This underlines the importance of acting immediately. NGOs and other practitioners acting on the ground and helping governments have a responsibility and a possibility to make a difference. They can create an environment were e-services applications are harnessed by both genders in the region. Women in CEE and the CIS are using the new services far less than men. The exclusion from creating e-service content diminishes women's possibilities of finding their roles within the growing e-service in business and governance. Access and education, content and decision-making and research are all interlinked structures. In the process of creating policies all these issues are important to establish a good environment not only for equality but also for the future of e-services in the CEE and CIS region.

KEY TERMS

CEE: The region of Central and Eastern Europe include; Estonia, Lithuania, Latvia, Slovenia, Serbia and Montenegro, Bosnia and Herzegovina, Kosovo, Macedonia, Croatia, Albania, Czech Republic, Slovakia, Romania, Bulgaria, Hungary, Malta, Poland, and Cyprus, Turkey.

CIS: The region of Commonwealth of Independent States include; Ukraine, Belarus, Armenia, Russian Federation, Georgia, Moldova, Kyrgyz Republic, Kazakhstan, Azerbaijan, Tajikistan, Turkmenistan, and Uzbekistan.

Disaggregated Data: Simply displaying/analysing data by specific subgroups, in this case gender. Using disaggregated data you can uncover patterns, trends, and other important information.

Digital Divide: Defined as unequal possibilities to access and contribute to information, knowledge, and networks as well as to benefit from development enhancing capabilities of ICT (Accenture, 2001).

E-Democracy: The use of electronic communications to enhance the degree and quality of public participation in government and in the public decision-making process.

E-Service: Viewed as any service or functionality that can be accessed by a business, organisation, authority or a consumer programmatically on the Internet, using standard representation and protocols. It refers to a technology-based service which can offer and includes information, interaction, transaction, and integration within business or authority.

Gender Empowerment: Refers to increasing the political, social, or economic strength of individuals or groups, in this case gender. It often involves the empowered developing confidence in their own capacities. Gender empowerment is measuring gender inequality in basic dimensions of empowerment, for example economic participation and decision-making, political participation and decision-making and power over economic resources.

ICTD: Information and communication technology for development refers to and focus on extending access to ICT, capacities to use it and the deployment of it to address various development opportunities. Levels such as the policy, capacity, infrastructure, content, and organization are addressed. Using ICT as an enabler for development (Accenture, 2001).

Millennium Development Goals (MDGs): Goals that the United Nations agreed on in 2000. The goals with time-bound targets and indicators should serve as an instruments to address the world's most challenging developments. The eight goals are:

1. Eradicate extreme hunger
2. Achieve universal primary education
3. Promote gender equality and empower women
4. Reduce child mortality
5. Improve maternal health
6. Combat HIV/AIDS, malaria and other diseases
7. Ensure environmental sustainability
8. Develop a global partnership for development (www.millenniumcampaign.org)

ENDNOTES

[1] The sum of fixed lines in operation and cellular mobile subscribers divided by the population of a country and multiplied by 100. Which make the possibility of double counting a major drawback (ITU, 2003, p. 73-75).

[2] Lithuania, Estonia, Latvia, Poland, Slovenia, Hungary, Cyprus, Slovakia, Czech Republic and Malt

Gender and ICT Policies and Programmes in an Indian State

Malathi Subramanian
University of Delhi, India

Anupama Saxena
Guru Ghasidas University Bilaspur, India

INTRODUCTION

The development and use of information and communication technologies have stimulated huge changes in the life of people globally, leading to a process of transition from the industrial to the information society. The ultimate aim of the information society should be the empowerment and development of all its citizens through equal access to and use of information (Goulding & Spacey, 2002).

BACKGROUND

Unfortunately, despite the potential ability of information to empower disadvantaged groups and the massive investments in information and communication technologies, the information society has remained largely silent on gender issues (Jansen, 1989). There is evidence of a gender imbalance in the use of ICT that threatens to restrict women from being equal partners and beneficiaries of the emerging information society, thus creating a gender-based digital divide. Decades of experiences have shown that without explicit attention to gender in policy, gender issues are not considered for implementation (Hafkin, 2002). Policy making in technological fields often ignores the needs, requirements, and aspirations of women unless gender analysis is included (Marcelle, 2002). If gender issues are not articulated in ICT policy, it is unlikely that girls and women will reap the benefits of the information age (Hafkin). Closing one's eyes to this fact can entrench inequality and even enlarge the gender gap, making ICT a "gender-negative" technology (United Nation's Development Programme [UNDP], 2003).

Thus, the issue of mainstreaming gender into ICT policies and programmes in the context of India becomes important, as here the ICT policy and programmes have been viewed by national and state governments largely within neoliberal macroeconomic frameworks of gross domestic product (GDP), employment, and competitiveness (Gurumurthy, 2003) rather than as issues of development or empowerment as well. Moreover, as in most of the developing countries, ICT education in India is largely confined to cities as the institutions that offer ICT education are urban based. While there may be a marginally increased enrollment of women in technical institutes in the last two decades, this has not resulted in more women in ICT-related careers or at decision-making levels. Women are vastly underrepresented in government, business, and social and political institutions even in the urban context. Men still hold most of the management and control positions in ICT-related employment and policy-making bodies. In the ICT-related employment sector, males account for 70 to 75% of the workforce. It has been held that even in the urban context, in the period following education, mobility or a lack of it is a crucial factor that affects the access to ICT and networking capacities of women, which is reflected in the extent of the presence of women in this sector (Pichappan, 2001). Women in India are considered to be the most socially excluded group, and a lack of access to information is being identified as one of the most important reasons for their exclusion (Hooper, 2003). This lack of access to information has added to their alienation from mainstream development activities and empowerment, resulting in increased social exclusion and economic and political marginalization, especially of rural, tribal, and other socially disadvantaged women of India.

A Brief Profile of the Indian State of Chattisgarh

Chattisgarh is a newly formed state of India that came into existence in the year 2000. It is a state richly endowed with natural resources but also marked with severe poverty, backwardness, illiteracy, and ignorance: 79% of the state population lives in rural areas, 32.55% of the population is of scheduled tribes (STs), and 12.22% is of scheduled castes (SCs). During 1999 to 2000, the state was third in share of the rural poor in India, with 11.35% of the total poor. Its low position in social and economic infrastructure and development is well documented (Dev, 2004; Kannan, 2004). The state has been ranked second to last in the list of all Indian states for telecommunications density (report of the Ministry of Communications and Information Technology, http://www.trai.gov.in/dld1.html).

Women in Chattisgarh

Women in Chattisgarh are visible in every walk of life, be it in agriculture, in the collection and processing of the state's rich forest wealth, or in construction and wage work in urban areas. Contrary to the situation in many parts of India, Chattisgarh enjoys a comparatively favorable position in terms of women's population as reflected in the sex ratio, which is 990 females to 1,000 males (census of India, 2001, http://www.censusindia.net/). However, in terms of infant mortality rates, its record is 97 girl deaths out of 1,000 infants, which is the highest in India (Rustogi, 2003). Furthermore, during 2000 to 2001, the school dropout rate (Class I-VIII, i.e., grade one to grade eight in schools in India) in Chattisgarh was 47.15%. This rate was higher among the SC (49.95%) and ST (63.68%) categories. Also, the female dropout rates were much higher than those of males (social infrastructure document, http://chhattisgarh.nic.in/opportunities/Social%20Infrastructure.pdf).

ICT Policies and Programmes

Nevertheless, with the formation of a separate state for its people, the state is aspiring for the prosperity and growth of its people (state vision document, http://chhattisgarh.nic.in/vision/new/Chp%205%20-%20Unlocking%20Natural%20Wealth.PDF). Expressing its commitment toward the development of its woman population, the state has envisaged a very ambitious and comprehensive women's policy (http://chhattisgarh.nic.in/wcd/womenpolicy.PDF). Realizing the importance of ICT, Chattisgarh also has a very comprehensive and ambitious IT policy (http://chhattisgarh.nic.in/policy/IT%20Policy.pdf). After its emergence in November 2000, the state government launched a number of ICT-related schemes and programmes for the benefit and development of its people, which are listed as follows:

1. **Bhuiyan:** All land records are computerized under this scheme. By paying only rupees, anyone can get a copy of the land records. Implemented in all Tehasil (Block) headquarters of the state, it is also planned to be extended to the villages at a future date.
2. **E-Sangwari:** This scheme is implemented with the objective of providing seven services to common citizens and was launched in the Bilaspur district only: (a) death certificates, (b) birth certificates, (c) caste certificates, (d) Form 16, pertaining to income tax, (e) khasaras (land records), (f) income certificates, and (g) domicile certificates.
3. **E-Kosh:** This scheme started in December 2004 to computerize all treasury transactions of the district headquarters.
4. **E-Panchayatas (Local Self-Government Units):** This programme was launched on January 26, 2005. It is executed through janpad panchayatas (local self-government units). Each janpad panchayata is given two computers that will be linked by satellite. The total cost of the project is over 9 million rupees, excluding the cost of software and satellite linking. It is sought to be an informative programme aimed at informing the rural people about the development and welfare schemes, and making available forms online. It is expected to be interactive in the future.
5. **Videoconferencing:** This programme was launched in January 2001. The heads of various government departments answer the ques-

tions asked by the common people through videoconferencing. It is being operated daily, and according to the officer in charge, 8 to 10 questions are asked daily.

6. **Feedback:** Most of the departments of the government are on the Web with the facility of a feedback system. Any citizen of the state can register any complaints or suggestions related to any of the schemes or programmes of the state government through the Internet. The complaint or suggestion is directly sent to the concerned department or official online. The status of the application or complaint can also be ascertained online.
7. **Wireless Loop-Line (WLL) Telephone:** Bharat Sanchar Nigam (the central agency providing telephone and Internet services all over India) has provided at least one phone to each village under this scheme with a 50% subsidy of the total bill. At some villages, Internet facility is also being started through this.

The ICT-related schemes listed attempt to make administration more citizen friendly in that earlier, obtaining these services involved visits to the offices concerned, often requiring a lot of time and effort. Making these schemes available on the Internet has also made it possible to obtain feedback from the public at the users' end, which was not easy earlier. The use of the Internet in administration in that sense is aimed at collapsing the distance between the officials and the public. In the Indian context, since before the ICT-based administrative schemes were introduced, it has been primarily men rather than women who often come into contact and interaction with officials (also mostly male) in administration. This is an activity in the public domain, which is traditionally male dominated, and is also considered largely the responsibility of the man in male-headed Indian families. The use of the Internet in administration could put the schemes within the reach of women without them having to move from their locales. However, this has not happened as assumed with the ICT-related policies and programmes, which aim at bringing administration within the reach of every citizen.

ICT Programmes and Women in Chattisgarh

Field surveys show that while it is generally assumed by policy makers (mainly male) that ICT policies and programmes will benefit men and women equally, the ground reality is that there is a vast difference in the availability, use, and access of ICT facilities for men and women. Hence, it is necessary to examine the gender perspective in the ICT policies and programmes. The ICT policies, programmes, and schemes in Chattisgarh seem to bypass the question of women's capacity building and empowerment. The impact of these policies at the user end for women is one of exclusion due to various reasons that need to be addressed urgently to avoid the digital gender divide superimposed on the already existing gender disadvantages for women arising from sociocultural factors (Nadamoto, 2003). Without a gender perspective, the low participation of women in accessing and using the ICT-based facilities may not be noticed. This is the case in the Chattisgarh region where even in urban areas, as compared to men, a very low number of women use the Internet-based facilities and services such as videoconferencing with public bodies; accessing Internet-based services like e-sangwari for obtaining records regarding births, deaths, or land; or using local government-information kiosks for obtaining information under the e-panchayata scheme. In fact, very few women have telephones registered in their own names. Similarly, in the educational sphere, there is low enrollment, retention, and visibility of women in ICT-related courses of study. Thus, in the Indian context, where women are already less visible in the public spheres due to sociocultural factors and men already dominate, ICT schemes are more available and accessible to men. This is also because ICTs have masculine connotations due to the traditionally larger presence of men in technological disciplines. Such is the picture in urban areas in Chattisgarh where more women are literate, are aware, and face comparatively less sociocultural constraints. Even if these programmes and facilities based on ICT are made available in the rural areas, women would still find it difficult to benefit from them due to the already existing limitations of a male-dominated society, especially those in areas dominated by the scheduled castes and tribes, who have been recognized as disadvantaged and who suffer from severe poverty, illiteracy, and backwardness, added to by the domination of patriarchal values, traditions, and attitudes.

While the state government of Chattisgarh is using the Internet in publicizing its various polices and programmes, advertising tenders and contracts, and making available the application forms of various schemes, in the absence of any capacity-building measures for women using ICT, at the operational level it is difficult for women to benefit from these schemes as they are unable to access the schemes due to various reasons located in the sociocultural milieu in which women are already disadvantaged. Traditionally, the households in India, whether in the urban or the rural sector, are male dominated, with the sphere of functions and activity related to the household clearly demarcated for women, which restricts their mobility in the public domain. This is reflected in women's choices of courses of study, the fact that very few are opting for and remaining in IT-related courses, and women's low presence in decision-making structures, even in urban areas where most of the ICT-related educational and training centres are found, where ICT-based programmes and schemes are being implemented, and where more women are educated and aware. In the rural areas, particularly in the backward areas and where socially disadvantaged sectors already exist, the digital divide accentuates the existing disparities both for men and women. For women who are situated in a rural backward area, it is doubly accentuated in that the well-intended ICT programmes and schemes do not reach them due to the urban bias in these programmes, and also because of the already existing gender disparity in the sociocultural milieu.

As ICT is becoming a popular and powerful tool for opinion formation through the dissemination of information, women's voices remain unheard while the men continue to dominate the common public discourse and opinion. The increased use of ICT in business is also benefiting mostly men as that sphere is also male dominated in India. In this sense, it could be said that the ICT-based services could further accentuate the dominance of men even though it may be intended to benefit all citizens. The ICT-based services, instead of being a means of empowerment and development of women, may in fact help in perpetuating the existing male-dominated gender patterns and biases in the society unless the issue of capacity building and empowerment of women is addressed.

FUTURE TRENDS

It is obvious from the foregoing analysis that without including the gender perspective into ICT policies and programmes, the potential benefits of ICTs may bypass girls and women, leading to a gender-based digital divide accentuating the preexisting gender imbalance. Access to and use of the new technologies may be directly linked to the social and economic development of women. In the Indian context, for instance, after the death of their husbands, without death certificates, many women face difficulties in getting the family pensions or rights over the properties of their husbands. Likewise, because of the lack of access to land records, it becomes difficult for women to sell or buy land without the help of a male. Similarly, as the videoconferencing facility is available only in the district headquarters, it is almost impossible for rural women to visit the site without the male members of their families. Thus, if women do not have access to and control over these technologies, it may result in their further marginalization from the economic, social, and political mainstream. Indian rural women comprise a social group that is already disadvantaged in the predigital society, and there is a threat that when it comes to the prospect of participating in and benefiting from the emerging information society, they will again find themselves doubly disadvantaged.

CONCLUSION

Technology has actually been historically and culturally construed as masculine. There has been a tendency toward the division of disciplines into masculine and feminine. For instance, arts, literature, languages, social sciences, and teachers' education are viewed as feminine. On the other hand, professional disciplines such as engineering, agriculture, medicine, commerce, and law have been traditionally perceived as masculine. More women are enrolled in the so-called feminine disciplines. As a result, women are conspicuously absent from the decision-making structure of ICT policy and programmes, resulting in the absence of the gender perspective in ICT policies and programmes.

Women's organizations, the office bearers of women's wings of different political parties, and other gender-focused organizations do not consider ICTs as a development concern or as an advocacy or political issue.

There is sometimes the problem of conceptual clarity regarding the modalities of gender mainstreaming among policy makers, those who implement them, development workers, and even among the academia. This lack of clarity or awareness, either conceptually or in operationalization, of gender mainstreaming and the resultant uncertainty have often led to nothing being done substantially apart from the mere use of some new words without much change in intentions or consequences for women

There is a often a common tendency in India among policy makers and among those who implement them to treat some areas as gender neutral, and this is the case with the ICT policies and programmes in Chattisgarh.

The patriarchal character of society and the well-entrenched patriarchal attitudes creep into the formulation and implementation of the ICT policies and programmes.

Unless a gender perspective is mainstreamed into policies and programmes, ICT is likely to remain a male-centric technology benefiting mostly men and depriving women, especially those who live in rural areas and those who are already socially disadvantaged as in Chattisgarh. There is an urgent need to ensure adequate measures in this direction to ascertain equal benefit and use of ICT for women.

KEY TERMS

Digital Divide: The digital divide is defined as the disparity between individuals with and those without access to a computer and the Internet. The divide is applicable to all population sectors encompassing both adults and children, but the focus of much attention has been on segments of the population seen as underserved: people in low-income, rural, and multicultural areas, and women.

Gender: Gender refers to socially constructed rather than biologically determined roles of men and women, as well as the relationship between men and women in a given society at a specific time and place. These roles and relationships are not fixed but can and do change in the light of evolving needs and opportunities.

Gender Mainstreaming: Gender mainstreaming was defined by the United Nations Economic and Social Council in 1997 as a strategy for making women's as well as men's concerns and experiences an integral dimension of the design, implementation, monitoring, and evaluation of the policies and programmes in all political, economic, and social spheres so that women and men benefit equally, and inequality is not perpetuated.

Gender Neutral: Gender neutral means a policy or programme that purports to, or is assumed to, impact men and women in the same manner. (It could also mean a lack of gender awareness or even "gender blindness," i.e., not conscious about the ground reality about the position of women in a particular society.)

ICT Policy: An ICT policy is an integrated set of decisions, guidelines, laws, regulations, and other mechanisms geared to directing and shaping the production, acquisition, and use of ICTs. Because the ICT sector is heterogeneous, extending beyond traditional classifications of industrial or services sectors, and because the production and diffusion of ICTs are of equal importance, policies in the ICT sector intersect with a number of other areas of policy making: technology, media, industrial, and telecommunications policy, and so forth.

Primitive Tribes: The most backward groups of Indian tribes.

Scheduled Castes (SC): The socially disadvantaged section of the Indian society on the basis of the caste system, identified for affirmative action by the Indian constitution.

Scheduled Tribes (ST): The indigenous people of India, the forest dwellers commonly known as tribes, identified for affirmative action by the Indian constitution.

Gender and ICTs in Zambia

Kutoma Jacqueline Wakunuma
Coventry University, UK

INTRODUCTION

This article looks at gender equality combined with social and economic empowerment within the context of information communication technologies (ICTs). It discusses rhetoric surrounding the promotion of ICTs as tools for social and economic empowerment and subsequently challenges whether such rhetoric does mirror the real situation on the ground, especially as it relates to developing countries like Zambia. The main focus is underprivileged women, especially those in rural areas, and how access, or indeed the lack of it, to ICTs like the Internet and mobile phones does actually affect their daily existence.

BACKGROUND

There has been a great deal said and written about ICTs. A lot has been achieved and made possible through the accessibility, possession, and use of these ICTs. This includes learning, politics, shopping, and all kinds of businesses online, particularly in developed countries (Castells, 1996; Howard & Jones, 2004). In essence, what former United States President Bill Clinton had envisaged back in 1997 in his *State of the Union Address* has come to fruition and been mirrored by most developed countries. He stated,

the new promise of the global economy, the information age, unimagined new work, life-enhancing technology, all these are ours to seize. As the Internet becomes our new town square, a computer in every home, a teacher of all subjects, a connection to all cultures, this will no longer be a dream but a necessity. (Clinton, 1997)

Today, ICTs are indeed no longer a dream but a necessity in most parts of the developed world, hence their becoming part and parcel of everyday life to most. In this respect, ICTs are having a major impact on people's lives. However, there is ambivalence as to what kind of impact they might be having on developing countries (Shade, 2003), more so when it comes to the underprivileged rural populace who are usually women. For instance, despite acknowledging how new technologies are impacting most aspects of daily life, Mansell and Silverstone (1997) are cautious and advise to tread carefully as far as the technologies are concerned. They assert that "simplistic utopian or dystopian visions of the future provide us neither with an understanding of how these changes come about nor with an understanding of the longer-term implications" (p. 3). It would seem Mansell and Silverstone are concerned that despite the assumptions of social and economic benefits, there may be a lack of in-depth analysis of exactly how such benefits are possible.

Having stated that, one cannot ignore that a developing country like Zambia, situated in sub-Saharan Africa, with all its social and economic challenges, has also recognised the global influence and to an extent is experiencing the impact that these new ICTs are bringing. The country has advanced apace and is experiencing a permeation of ICTs, particularly in the form of mobile phones and the Internet. This permeation has meant a steady growth in their accessibility and usage, especially in urban areas. Since the introduction of these technologies in the 1990s, urban areas in Zambia, for instance, have seen a steady mushrooming of Internet cafes and an increase in mobile-phone usage. However, rural areas do not tell a similar story even though 65% of the country's slightly under 11-million-person population live in rural areas (Republic of Zambia Central Statistics Office, 2004). According to the statistics office, of the country's total population, 51% are women while 49% are men. The country's population also accounts for about 2 million households of which 66% are rural households. Of the 66% rural households, 68% are female-headed households whose survival depends on rural small-scale farming in addition to all the traditional stereotypical roles they have to attend to. For these rural dwellers, this has meant that the lack of a significant penetration of technology into their areas when pitted against the urban setting has deprived them of ICT accessibility and use. There are several reasons that can be attributed to this lack of penetration, some of which are that Internet and mobile-phone growth has been concentrated along the commercial line of rail where infrastructure exists. One clear impact of this permeation of ICTs, especially where mobile phones are concerned, has meant that mobile-phone ownership and usage has surpassed that of fixed landline ownership (Munsaka & Habeenzu, 2004).

This is in spite of the high price of acquiring and maintaining them because of the poor economic situation of the country. Other reasons why mobile-phone ownership exists more than that of fixed landline phones is because there is no bureaucracy in acquiring a mobile phone as there is when applying for a landline. In several cases, one has to wait for a while before a landline phone can be installed. Additionally, mobile-phone service providers are reaching and serving some parts of the country that were previously unreachable by the country's sole landline provider. For example, there are now approximately 450,000 mobile-phone subscribers compared to around 86,000 fixed landline subscribers. Adding on to that, there are around 13,000 Internet subscribers with an estimated 50,000 users (Communications Authority of Zambia, 2004). Evidently, there is substantial shared Internet use, particularly in public places like Internet cafes, universities, and even companies.

MAIN THRUST OF THE ARTICLE

Despite the continued growth, looking at the figures of subscribers and consequent users given above, the number is relatively small when compared to the country's population of slightly fewer than 11 million people. This is also bearing in mind that most of these subscribers and users are found in the urban areas of Zambia and are mostly men. Due to a lack of gender-disaggregated data, it is difficult to state how many women compared to men are Internet or mobile-phone subscribers or indeed users, but it is generally agreed that the greater number is biased toward men. Having carried out fieldwork in Zambia from November 2004 to March 2005, the author found that both men and women felt that men had more and easier access. The respondents also disclosed that more men than women used mobile phones and the Internet. To get this information, the author conducted one-to-one interviews with, among others, policy makers, nongovernmental organisations, and underprivileged men and women, especially those in the rural areas. There were also 390 questionnaires administered to 209 men and 181 women, and focus-group discussions and observations.

The Zambian society is very much a patriarchal, hegemonic, and hierarchical society where men have more advantages than women and where inequality between both genders seems to be the norm. It therefore came as no surprise that respondents confirmed that men were more advantaged when it came to ICT accessibility and use. Some of the reasons given were that men were more financially stable, were more educated, had better access to employment, and generally had more time to access and use the technologies while women, aside from their lower educational attainments, had additional household and family chores to do. Supporting these findings, official government statistics confirm that in Zambia there are more men than women receiving higher education. Also, there are more women who are unemployed than there are men (Republic of Zambia Central Statistics Office, 2004). The government in effect accepts that there is a problem of inequality when it comes to accessing and using ICTs. In its 2004 Strategic Plan of Action for the National Gender Policy, the Zambian government indicates that women are unfairly and unequally represented in the media, that women have no say in communication, and that girls and women lag behind in engaging with science and technology subjects (Republic of Zambia Gender in Development Division, 2004). In this regard, the gender imbalance of technology is not surprising, as several studies have shown (Cockburn & Ormrod, 1993; Wajcman, 1991). These studies indicate the gendered aspects of technology and also show that technology is not neutral. Faulkner and Arnold (1985) summed this aspect when they pointed out that "ultimately, the power of modern technology emanates from the powerful in our society, and reinforces their power. As in other areas of our patriarchal and capitalist society, those with power are predominately male" (p. 1).

Although there are seemingly a minimal number of ICT users in a developing country like Zambia and the obvious difficulties and problems of gender inequality in the use and accessibility of ICTs, scholars like Harcourt (1999) and Negroponte (1995) express optimistic views of the new technologies. Negroponte enthuses that the digital age can be "harmonizing and empowering" (p. 229). One can take it that such optimistic views seem to imply that the new technologies may eventually be able to sustain both social and economic development. This optimism is seemingly shared by policy makers' rhetoric at the local and international levels. Policy makers have indicated and consequently advocated for the use of ICTs in order to realise social and economic empowerment, especially for women who are the marginalised gender. For instance, at the local level, in its draft national ICT policy, the Zambian government indicates that its mission is "to enhance and accelerate sustainable economic growth and social development through the provision of affordable and universally accessible ICTs" (Republic of Zambia, 2004, p. 5). In continuing further, the policy states the need to "increase participation and empowerment opportunities for youth and women in national development through ICTs" (p. 17). At the international level, the United Nations' optimism of ICTs' potential in achieving gender equality as well as harnessing social and economic development is evident in its World Summit of the Information Society (WSIS) Declaration of Principles. Part of the declaration states that the "challenge is to harness the potential of information and communication technology to promote development goals; the eradication of extreme poverty and hunger; promotion of gender equality and empowerment of women" (United Nations, 2003, p. 1).

The question that needs to be asked then is whether all this rhetoric mirrors actual reality on the ground. Can what ICTs have done in the West be done in the developing world? Are there signs that developing countries like Zambia are getting to the level where developed countries have gotten to in terms of ICT innovation, accessibility, and use, or is this just mere rhetoric such that there is no change, especially for the underprivileged rural women?

The author is by no means trying to undermine the importance of ICTs because there is no ignoring the positive potentials they bring. However, the point the author is trying to assess is to what extent this potential is. By having access to these ICTs, is there a difference being achieved in terms of what may seemingly be more pressing issues to communities such as inadequate water, food, shelter, or education? Are ICTs making a major difference, or any difference at all for that matter, to a woman who is expected to wake up at the break of dawn to gather firewood and make fire to prepare bathing water and food for her husband to find ready when he wakes up? After all this, she then has to proceed to the field to cultivate her crops and then come back to prepare food while the husband rests and waits for his wife to tell him food is ready. These may seem simplistic examples, but nonetheless, these are situations most women in the rural parts of Zambia have to contend with everyday of their lives. No doubt, when they are lucky enough to have access to ICTs like mobile phones, they do take advantage of them. However, the cardinal question still remains, which is whether there is appreciable improvement to their everyday existence.

The prospects for social and economic benefits may promise the alleviation of problems like poverty and hunger that most developing countries are experiencing, but the idea that ICTs can be catalysts for the alleviation of such problems by simply being accessible seems both too simplistic and idealistic at the very least. It is simplistic and idealistic because one would argue that there is much more to ICTs and development than mere access. The digital divide, for example, shows that old, traditional social inequalities still persist. These include social inequalities between rich and poor countries, between the rich and poor in developing countries, as well as those between men and women. The dichotomies of accessibility and inaccessibility, rich and poor, and to have and have not seem to persist constantly. This shows that the traditional social hierarchical power structures could be more divisive in the adoption of ICTs. The problem of such dichotomies is not only in developing countries, but in the developed world as well (Evans, 2004), though the scale may differ. These inequalities and/or disadvantages then occur and intersect within other social categories of sex, gender, class, and even race (Servon, 2002). This makes access, as a route to empowerment and development, seem somewhat more complex than often assumed. As such, it is perhaps not surprising that commentators like Mansell and Silverstone (1997), as cited earlier, may seem a bit sceptical of views that ICTs might result in social and economic development, especially for socially disadvantaged groups like most women in Zambia.

The rhetoric of information as being a catalyst for social and economic development may be right to a certain extent, but mere access to ICTs will not automatically be empowering. Perhaps this can only happen when one has the privilege of being privy to other factors of life such as shelter, food, knowledge to understand the importance and use of such ICTs, justice, and capacity in terms of capital to be able to change with the dynamism with which technologies come and go. That may also explain why there is just a fraction of users in Zambia who have access: Those are the privileged few that can afford to have access. Additionally, in this day and age, information is becoming more and more commercial. As such, for those without the means to purchase it, information will continue being unevenly distributed and hence unhelpful in bringing empowerment (Lax, 2001). Thus far, there is an obvious hindrance and exclusion to the benefits that ICTs can bring to those who cannot afford to have them. On the other hand, there is a lot of truth in the point that with ICTs have come a whole wealth of information previously thought inaccessible by many people. One only has to go to a search engine and type in a request, and a flurry of information pops up. However, there are still evident hierarchies in what type of information one can access, who can access it, and to a large extent at what cost.

There is evidence as witnessed by the author during her fieldwork that the position of most rural and underprivileged women in Zambia is not really changing due to the use of ICTs. If anything, their stereotypical subordinate situation might be more glaringly obvious. Also, the economic change might not be that significant to warrant an economic emancipation. During the fieldwork, some women expressed concern about the new ICTs, particularly the mobile phone, because the mobile phone was actually ruining their marriages or partnerships. One woman pointed out that she had to sell her mobile phone because it was bringing a lot of noise and misunderstanding between herself and her husband. She stated that her husband became paranoid and started suspecting her of extramarital activities. On the other hand, she did not understand why her husband had to go outside to answer his mobile phone whenever it seemed there was a woman on the other end. When confronted, her husband either became uncompromising or said it was just a mere male friend when in fact it was a female's voice she would usually hear. Unfortunately, she could not do anything about it as her husband was the head of the house and was therefore superior to her.

This example shows that in certain situations, there is no negotiating power; women are in a constant battle where power is concerned and often do not have it. Their position is actually reinforced and in some cases made worse through the use of ICTs. To the question of whether the Internet or mobile phones were empowering them, the common response of most women and men indicated that their daily existence had not changed, but they were merely able to cut down on travel costs. They also disclosed that it was quicker to get in touch with either friends or relatives, or to check up on debtors. However, in the same vein, most pointed out that the cost of maintaining their mobiles or using the Internet when they could was too expensive. One female respondent pointedly stated the following:

Why would I want to use the Internet or spend money buying a mobile phone when I have to make sure there is food on the table for my family? Will the Internet feed me or give me food to take to my kids? I think not!

For those who had mobile phones, how much their access and use of ICTs measured to their everyday struggles was quite difficult to quantify. If anything, they felt the changes were too minimal to point to as success stories. The established unequal gender differentials were still very much in existence and were showing no obvious signs of improving. It was also clear that there were still a lot of problems women were experiencing with or without the new ICTs.

FUTURE TRENDS

While there has been a plethora of research on gender and ICTs, particularly in developed countries, there seems to be very little research done in developing countries like Zambia that has challenged policy makers' rhetoric. What seem evident are anecdotes on how empowering ICTs are and how they can bring gender equality as well as social and economic emancipation. More critical analysis into such assertions is of utmost importance.

CONCLUSION

In more ways than one, ICTs have changed the world for the better. However, for most underprivileged people, especially women in rural areas, the opposite may be true. It would seem that such groups of people do not attach a great deal of importance to ICTs, but rather to immediate needs of food, shelter, health, and education. Perhaps they also feel that ICTs are not necessarily the only answer to their everyday lives and that there may be other ways and means with which to engage in order to answer social and economic problems. As the traditional stereotype relations between men and women continue to persist, a gender balance is also questionable when it comes to engaging with ICTs.

KEY TERMS

Developing Countries: Unindustrialised countries with low per-capita incomes.

Gender Balance: Equal opportunities for both genders with respect for differences.

Gender Differentials: Different social constructions between men and women in which women are usually treated unfairly in, for example, social and economic settings.

ICTs: Information communication technologies like mobile phones and the Internet.

Rhetoric: Effective and persuasive talk about how good ICTs are than actually may be.

Rural Poor: People living in areas far away from large cities often in thatched huts with inadequate amenities like electricity and transport.

WSIS: The World Summit on the Information Society is a United Nations body whose purpose is to ensure that benefits in areas like e-commerce, e-governance, e-health, education, literacy, and gender equality are possible for all.

Gender and Information Technology in Rural Bangladesh

Lutfor Rahman
Association for Advancement of Information Technology (AAIT), Bangladesh

Nusrat Rahman
University of Dhak and Association for Advancement of Information Technology (AAIT), Bangladesh

INTRODUCTION

Information technology (IT) is transforming our personal, social, cultural, economic and political lives. But women in developing countries do not have equal access to knowledge, due to the fact that they do not have access to the new technologies at the same level as western European women. They need to understand the significance of new technologies and use them in relevant fields. IT can offer immense opportunities for virtually all girls and women in developing countries, including poor women living in rural areas.

Developing countries like Bangladesh are usually seen as problematic hosts for ITs because most developing regions of the country lack economic resources and indigenous techno-scientific capabilities to develop and deploy IT infrastructures. The regions also tend not to make the best use of opportunities of technology transfer.

The wider adoption of IT in the 1990s promised a globally connected community of equal participants in electronic networks. The Internet has enabled people to communicate regardless of race, sex, physical ability, location and social background (GVU, 1998). IT now offers access to a huge pool of information. The Internet enables worldwide communication that is cheaper, faster and more flexible than older media like e-mail, telephone, telex or fax.

BACKGROUND

In early 2000, an initiative was taken to develop a small river island (char) of Bangladesh through establishment of a resource centre named Indigenous Science and Technology at Ikrail (ISTI), and using IT as the main vehicle for development. IT is a livelihood to many women of the developed countries but is almost unknown to the women and girls of the river island.

Women in Bangladesh are seen in the frontlines to fight against hunger, poverty and environmental degradation. Because of lack of awareness about the benefits of IT, they cannot raise their problems for solution to the proper authority. IT can benefit women in various ways and can facilitate their participation in different sectors and regions. It can provide information women need to improve their own well-being and that of their families. The introduction of computers in offices can improve the quality of work and scope for women in data entry, analysis, programming, clerical and administrative occupations in Bangladesh. IT could allow them to exchange views, opinions and information with women of other regions and countries.

The situation for rural populations in many regions of the world is characterized by geographical distance from urban centres that offer employment and income, education, cultural events and public services. IT bears the potential to improve the situation of rural people in several ways. For example, it is agreed that early diagnosis of medical issues can prevent many casualties. Once a patient comes to the health centre, using various sensors, information can be collected and communicated to an expert at hospitals in the district headquarters. The primary healthcare centre could be located in a rural area or in a mobile centre installed in a van.

IT offers access to information and extension, to education and training communication and networking in online discussions. IT also offers access to employment and income.

Infrastructural Problems

Poor healthcare can result from a lack of good information. Establishing reliable communications may be one of the most important priorities for improving healthcare and education. Many rural areas in the globe have no or outdated telephone lines that can transmit Internet-based data. The lack of infrastructure can be overcome by wireless technology (e.g., radio modems). Mobile telecentres can be a solution for the target group.

HEALTHCARE IT PROJECT

A significant number of women scientists, researchers and technologists work in rural Bangladesh. They are disadvantaged and traditionally underrepresented in most respects. Their knowledge and skills are unrecognized, underused and under valued. As such, they are in greater need of upgrading their skills, especially in the fast advancing world of information and communication technologies (ICTs), which might enable them to connect their global colleagues, sources of information and global knowledge wherever they may be located.

A survey conducted in early 2000 among 515 women professionals of various disciplines spanning life sciences, social sciences, physical sciences, mineral sciences, engineering, technologies and medical sciences identified that they are almost illiterate in IT, although they are well qualified and experienced in their respective fields. At the first step, the survey was conducted over the senior professors of the public and private universities, scientists of the Bangladesh Council of Scientific and Industrial Research (BCSIR), researchers of institutes of forest research, housing research, fuel research, jute research and water resource and geological research.

They have very poor knowledge about the power and benefit of IT. This trend was found true at all levels of educational backgrounds. The survey revealed that the illiteracy rate in IT among the medical doctors are high, because the doctors are normally resistant to new technology, particularly IT.

To reach the benefit to the rural communities, participants for IT training were selected from among applicants spanning all sectors, giving priority to the rural community. The representation covered various national economy, especially health, environment, education, natural resources (mineral resources), energy, industry, agriculture, fisheries and forestry. Special care was taken in selection of participants so that the maximum number of organizations and individuals would benefit from the program. Training programs on IT for the duration of 2 weeks were organized in different private universities at a certain interval with 20 participants in each phase. The programs were initially organized at the capital city, and later, the programs were arranged at the regional institutes and universities. The regional programs were mainly organized for the medical doctors working in the local hospitals, clinics, medical colleges and universities. Selection of participants from the women medical doctors was really a tough job. Neither the medical doctors nor their family members wanted to spare 2 weeks for attending a training course that they feel are good for their children, not for the doctors. Strategies were adopted to attract the medical doctors. As soon as they realized the importance of IT, they invested more of their valuable time to learn further applications. Ninety-two percent of the trained medical doctors were found to utilize their gained knowledge intelligently in their respective fields. The result was obtained from the follow-up visit by the project staff.

FUTURE TRENDS

Bangladesh is a country of rivers that create islands (chars) of different shapes and sizes. They are created because of river erosion. The ISTI resource centre is located in one such island. The island is circular in shape and its area varies from 20 to 30 square kilometers, depending on seasons. Approximately 15,000 people live in the island community. The people depend on local cultivation for survival. Their average monthly earning is $40 (United States dollars). The area is fertile and rice, wheat, peanut, jute, sugarcane, and different types of vegetables and fruits are common. All work is performed manually. The people are deprived of basic infrastructure. There is no electricity, phone system or sanitation. The only source of water is contaminated with arsenic. There are no health clinics or doctors in the area. Many adults are illiterate, and curable diseases, such as cholera, malaria and tuberculosis, are pervasive.

The ISTI resource centre has been established with the objective of developing this isolated region with proper education, empowering local people with relevant technology, particularly IT, and providing them with medical facilities using modern techniques (such as telemedicine and telehealth care). The ISTI resource centre, equipped with basic medical test equipment like stethoscopes, blood pressure meters and blood testing chemicals, and connected with a hospital located in the district town, might save lives of many women and girls. Just a computer with a modem connected with wireless local loop (WLL) help solve most of the serious problems of local women by the women medical doctors empowered with IT. The ISTI resource centre is working as role model for several million disadvantaged women living in the river islands of Bangladesh.

CONCLUSION

This training program has been particularly suitable and effective for relatively marginalized groups and remote communities in a developing country because of its low cost and the use of local organizers and trainers, courses especially designed to meet the participants' needs and in situ follow up. The direct involvement in the courses of senior policy makers, employers and local experts has proven to be absolutely crucial in gaining support for the continuation and expansion of the course and, perhaps more importantly, effecting attitude change to women's roles and capabilities in science and medicine. This was underlined by the increasing cooperation extended by them to the project team during preparation and execution of the project. The outcome of the whole training has been impressive. Participants' value to the work place has increased, some attained promotions and some changed careers.

The final evaluation report shows that most women medical doctors and other health-related professionals empowered with IT have expressed their opinions that every medical doctor must attend relevant technology—particularly IT—courses if they want to enhance their services and maintain their personal secrecies. Some mentioned that IT is a magic and all-pervasive tool.

KEY TERMS

Information and Communication Technology (ICT): ICT covers computing, electronics and telecommunications.

Medical Professionals: Medical doctors and scientists in health-related subjects, such as nutrition, bio-chemistry, psychology and so forth.

Researchers: Graduates and post graduates engaged in research activities.

Scientists: Science graduate with some research experience in scientific fields.

Technologists: Engineers and scientists with experience in hardware.

University: A university is characterized by a wide variety of teaching and research, especially at a higher level, that maintains, advances, disseminates and assists the application of knowledge, develops intellectual independence and promotes community learning.

Gender and IT in the Concept of Sustainability

Esther Ruiz Ben
Technische Universität Berlin, Germany

THE GLOBAL DIGITAL DIVIDE

New information and communication technologies are radically transforming the way that information and knowledge are disseminated and shared around the world. The digital divide between rich and poor countries is still persisting: more than 70% of the world's Internet users are based in Europe and North America, where—in addition—more than 90% of the data on Africa are stored. Similar gaps persist between urban and rural areas and between men and women, especially in developing countries. Rural women usually have less access than men to information and new technologies (Huyer & Mitter 2003). Lack of information and access to education related to IT also limits women's influence in their communities and their ability to participate in decision-making. When assessing the opportunities and risks of new technologies, it is essential to give attention to gender differences and to ensuring that women's voice is heard so that technological developments can be sustainable in the way that best prevents them from increasing inequalities. Particularly gender factors are crucial to develop a sustainable concept of IT evolution. Our aim in this article is to show how the concept of gender and IT can be integrated in a wider conceptual framework of sustainability. First, we will explain the concept of digital divide from a global perspective and the importance to understand the gender dimension within this conceptualization.

Concerns about the disparities between industrialized and developing countries, especially with respect to Internet access and use, have touched off a worldwide debate about the existence of a global digital divide. From a domestic perspective at a national level or even at a regional level thinking about the European Union for instance, the term digital divide has shown to have powerful symbolic weight, and hence to be a useful tool with which to mobilize political support for government programmes designed to bridge the gaps between so called "information haves" and "information have-nots." The OECD defines the "digital divide" as "…the gap between individuals, households, business and geographic areas at different socio-economic levels with regard both to their opportunities to access information and communication technologies (ICTs) and to their use of the Internet for a wide variety of activities. The digital divide reflects various differences among and within countries." (OECD, 2001, p. 5). Access to information and communication technologies is considered as the first stage to become an "information have." However, access is not limited to the infrastructures: an important factor contributing to the digital divide is the extended and hegemonic use of English as access language in the Internet. This is one of the reasons for instance, why the Hispanics in the USA a lower access to the Internet show as Wilhelm (2000) argues. Moreover, even among "information haves" or in other words, among those having access to information through information technologies we can observe digital gaps. DiMaggio and Hargittai (2001, p. 4) refers for instance to the ability to evaluate the quality of information: "By 'digital divide,' we refer to inequalities in access to the Internet, extent of use, knowledge of search strategies, quality of technical connections and social support, ability to evaluate the quality of information, and diversity of uses." This aspect is particularly related to the inequalities according to the educational level of the "information haves." Furthermore, when carried to the international level, the term "digital divide" arguably misconstrues the issue and is unduly pessimistic. For example, the term directs our attention to relative inequalities in the distribution of information age resources, when what really matters to the quality of life in a given country is its absolute level of resources and the efficacy of the institutional order in redistribution and social justice. Qureshi (2005, p. 1) refers to the results of a recent study about the digital divide showing that "it is access to information, services, and expertise through access to the network, combined with ICT skills that contribute to economic growth and a decrease in this gap." Instead of fixating on the existence of a divide, it would be far better to focus our attention on the "global digital opportunity," because that is what really confronts us today, an unprecedented opportunity to move swiftly up the path towards global digital development. From a gender perspective, it is important to improve the access of women, particularly women in underdeveloped countries and rural areas to knowledge and information through IT, but it is also important that women participate in the design and production of IT. We argue that the digital divide must consider also the gap regarding IT shaping. Shaping IT means nowadays in much extent shaping society and nature and thus we plaid for a concept of sustainable information society with a participatory approach that allows the integration of excluded perspectives and moving beyond consumerism fixations taking local voices and the co-evolution of nature and society as a point of departure. Particularly women's perspectives excluded in great extent through gendering processes must be taken into account as they reinforce other embedded inequalities factors such as education or age. Understanding gendering processes within the shaping of IT and society is crucial in the concept of sustainable information society. However, IT development constitutes also a complex co-evolution of nature and society in different world regions. Particularly sustainability scholars have attempted to define these both basic co-interacting spaces. In the next section, we show an overview of the basic assumptions of sustainability that have lead to a more focused concept of sustainable information society.

THE CONCEPT OF SUSTAINABILITY AND THE INFORMATION SOCIETY

The concept of sustainability addresses basically a balance of society-economy-environment interactions. It assumes that there exist limits to which the earth's ecosystems can sustain disruption, without, in turn, causing injury to human health, social and cultural systems, and economic interests. The concept of sustainability thus attempts to define both, environmental conditions contributing to a healthy and stable human existence, as well as activities that while not limiting our evolution to more sophisticated and justice living conditions, can help us to create such conditions. However, moralistic and normative issues of intergenerational and global equity drive to some extent sustainability discourses. According to the definition of the World Bank Institute, global equity refers to equal opportunity for livelihood and development across the world while intergenerational equity focuses on the balance of potential and opportunities for livelihood and development between future and current generations (World Bank Institute, 2000). This assumption represents a common perspective among scholars over the past two decades, although the diversity of sustainability theories.

Rachel Carson's book "Silent Spring" (1962) constitutes the base of what we call today the sustainable development movement (International Institute for Sustainable Development, 2002) which Garret Hardin (1968) in his classical article "Tragedy of the Commons" developed. Since then many different definitions of sustainability have been developed (Neumayer, 1999; Rees, 1995). However, most scholars refer to the 1987 Brundtland Commission definition of sustainability as a departure point: "Humanity has the ability to make development sustainable to ensure that it meets the needs of the present without compromising the ability of future generations to meet their own needs." (Brundtland 1987, p. 41)[1] This definition of sustainability presented by the Brundtland Commission (WCED, 1987) implies a subdivision into social, ecological, and economic dimensions. This tridimensional conceptualization of sustainability has been however extended including additional dimensions, as it is the case in the concept of Jacob (1996), who departing from the theory of science defines the different aspects of sustainability as being social, economic, political, and cultural. Other authors plaid also for the consideration of cultural dimensions (Kuhlen, 2004) or include an institutional dimension (Schneidewind, 2001) in the original triangle of sustainability. A related subdivision is used at the Wuppertal Institute, who has formulated a "Prism of Sustainability" (Spangenberg & Bonniot, 1998) with the three corners of the triangular base representing social, economic, and environmental imperatives. The top of the prism represents the institutional imperative and these four imperatives carry equal importance for a sustainable development. Further, the prism functions as a foundation for the development of indicators for sustainable development.

Looking beyond the point marked by the Brundtland Report and trying to give an overview of the general perspectives in the literature on sustainability, two basic points of view—"weak sustainability" and "strong sustainability" can be distinguished. Both these perspectives are focused on the preservation of environmental capital and seem to be in opposition to each other. The difference between these perspectives remains primarily in their assumptions about the nature of the natural capital. The weak sustainability (WS) perspective assumes natural capital to be substitutable (Beatley & Manning, 1997; Becker & Jahn, 1999; Pearce, Barbier, & Markandya, 1990; Sharma, 2000, 2003; WCED, 1987; World Bank Institute, 2000) through investment in new production forms and consumer goods, from the utilization of non-renewable resources to research on renewable resources. Neumayer (1999) thus calls this perspective the "substitutability paradigm" and refers to the concept of genuine savings of Hamilton (1994) as the green net national product. Genuine Savings Net is understood as the net national product augmented for investments in and deducted for deterioration of natural as well as other possible forms of capital. The strong sustainability (SS) perspective, on the other hand, conceptualizes natural capital as non-substitutable good (Brown, Kane, & Roodman, 1994; Daly, 1996; Ehrlich, 1986; Neumayer, 1999; Pearce et al., 1990). Natural capital consists from this point of view of renewable and non-renewable resources. Thus, scholars assuming strong sustainability approach suggest to stop the consumption of non-renewable resources and to maintain a rate of consumption of renewable resources that is less than the rate of regeneration of the renewable source for all time periods. Accordingly, to this concept Strong Sustainability is called the "non-substitutability paradigm." (Neumayer, 1999). We can also define these approaches as "techno-centrist" or "eco-centrist" (Eblinghaus & Stickler, 1996). The success of the strong sustainability strategy depends on the satisfaction of key institutional, political, and ethical requirements which include participation and inclusion of stakeholders in decision-making. Gender mainstreaming plays here a crucial role.

In 1973, Strong introduced the concept of eco-development that Sachs (1980) and later on Glaeser (1984) upgraded. These authors attempted to find convergences between ecological and development principles trying to define development paths for a balanced and qualitative growth instead of an "eco-centric zero-growth" in a similar way as the Brundtland Report in 1987. Particularly important at this time was the Chernobil accident in 1986. This catastrophe represents a crucial point leading to reflection about the risks of technological development. From a sociological point of view Luhmann (1987) and Beck (1986) represent some the most influent authors referring to the ecological risks in contemporary societies and to the interaction between society and nature. Institutions play a crucial role at this point in order to reach the resonance and reflexivity needed for a dialog between the self-referenced sub-systems of contemporary societies. The neo-institutional paradigm emphasizes since the eighties the necessity of social institutions as a fundament of social interaction. Sustainability as defined by the Rio conference is such a normative concept, which adds to projects of social development visions, and thus the possibility of shared goal orientation. Different types of social actions (e.g., eco-profit in economic sub-systems) can be subsumed under this culturally accepted goal. Well running projects of AGENDA 21 processes can be found now nearly everywhere in the world and illustrate, that by means of orientation at environmental norms different groups and parties of a wide range of interests can co-operate. Regional development programs include sustainability as well as participation of the civil society in its programs.

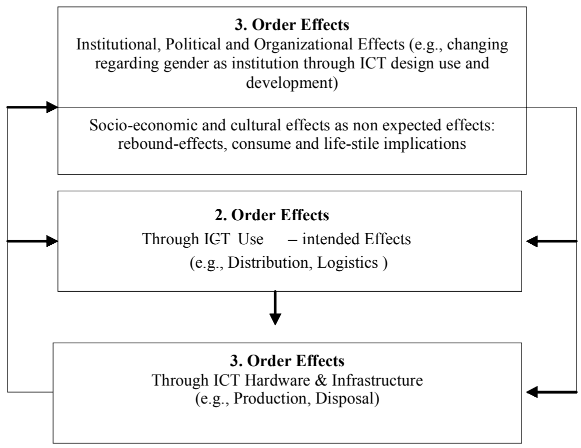
Under the concept of moral obligation, also the tension between regionalism and universalism can be stabilised (think global, act local). The recovery of the local in view of the global is one of the interesting points for regional social development.[2] Also the tension between utilitarism and altruism as different action orientations can be brought together in a regional perspective.

Taking these ideas as basis Schneidewind (2001) attempts to create a model of sustainable information society. Schneidewind (2001) distinguishes primarily between two dimensions considering the ecological implications of information technologies. Firstly, the effects of IT infrastructures (energy consume, electronic garbage, toxic products) and secondly the effects derivate of IT use, especially internet. Particularly this second dimension is very difficult to measure. Schneidewind considers that a socio-ecologic approach is needed here in order to measure the change in social structures and institutions as an effect of IT use. He distinguishes two interacting levels of research: First level effects (economic-structural effects or rebound-effects) and Second level effects (institutional-structural effects; for instance new governance structures). However, especially important in this approach is the conceptualization of sustainable information society as a developing path for institutions and organisations enabled through information and communication technologies. This means that information and communications technologies can help to reach new sustainable organisational and institutional forms through which side effects from a social, economical, or ecological perspective are controllable. Moreover, information and communication technologies can concretely help to improve the reflexivity of decision processes, participation, self organisation forms and justice forms of conflict regulation and balance of interests. Ruiz Ben and Quack (2004) have enhanced this model introducing a gender perspective as a transversal category. In the next section, we give a brief overview about the discourse on gender and sustainability and afterwards in a concluding chapter we will explain the adapted model of Ruiz Ben and Quack (2004).

GENDER IN THE CONCEPT OF SUSTAINABLE INFORMATION SOCIETY

The discourse on gender and sustainability has been marked in its origin by the earlier eco-feminism. Francoise d'Eaubonne first used the term ecofeminism in her l974 book *Le Féminisme ou la mort*. The eco-feminism has since then been associated with the idea that "women", animals as well as "nature" share a subordinate and instrumental relationship to hegemonic, mainstream men in global patriarchal practices. Moreover, they are embedded into patterns, attitudes, and institutions of male domination. More concretely, according to Kailo (2003) Davies describes ecofeminism as stressing the importance of a holistic approach to living, with holism implying that the planet is a single interacting ecosystem and that all forms of life are interdependent (Davies, p. 1988, p. 4-5). Another important aspect in Davies' theory is the principle of non-hierarchical systems following from the holistic emphasis on interdependence and leading to the complementarities and equal status of all parts of the ecosystem (Davies, 1988, p. 5). From the perspective of ecofeminism, hybridity, or challenges to the unified anthropocentric subjectivity as such does not represent a value, but the way the intermingling of humans and animals can lead to more respectful socio-ecological relations. As Merchant (1980) as one of the pioneer in this field has shown, liberal, Marxist, post-modern, cultural and socialist eco-feminists have applied the above principles with divergent emphasis and strategies for change. Merchant (1980) argues that nature was conceived on an organic model as a benevolent female and a nurturing mother before the scientific revolution. Afterwards nature was conceived from the perspective of mechanistic ideals as machine, inert, dead. The move from the organic to the mechanistic ideal enabled a justified exploitation of the earth. This mechanistic perspective replaced an older, organic worldview, which provided gendered moral restraints on how to deal with nature. Davies' work lead to the assumption of an existing connexion between the domination of the environment with economic purposes, the domination of unprivileged social groups, and a patriarchal hegemony. Plumwood (1991) argues that rationalism is the key to understand woman-nature connections in the Western world. Rationalism resides in a long-standing philosophical tradition assuming the premises of dichotomization (e.g., human-nature, masculine-feminine, reason-emotion, spirit-body) and privileging the human self as masculine and centred around rationality and excluding its contraries (especially characterized as feminine, animal, or natural). A more essentialist perspective brings Shiva (1988) in the eco-feminism discourse. This author emphasizes the ethical aspects of women as "care-takers" with a privileged natural role to nature. Feminism environmentalists have criticized this assumptions and plaid for a pragmatic and more materialistic

Figure 1. Overview of the effect-levels for the analysis of IT from the perspective of sustainability (Based on Ruiz Ben & Quack, 2004 on the basis of OECD, 2001; Fichter, 2001; Schneidewind, 2001)



approach. Thus Argawal (1992) for instance refers to the importance of customs, and social structures in defining women´s relationship to environment. Braidotti (1999) suggests updating the discourse of sustainability from a perspective of the:

historically marginalized others (woman, the ethnic other and the natural environment) as the signs of a crisis of modernity and of representation open up a multi-layered field, encompassing:

- *On a political level, coalition building among heterogeneous actors, the renegotiation of identity and a refiguration of subjectivity as a crucial task for social philosophy. Drawing on insights from feminist theory, a transformative trajectory built in the discourse of on sustainability might be discussed in terms of "differences within*
- *On an epistemological level, a re-examination of sciences, the dominant model of Western representation, implying also an outlook on how the ethnocentric and masculinist bias of science might be overcome.*

Taking this perspective as a departure point, we suggest integrating the concept of gender as a queer category in the analysis model of sustainable information society as we explain in the next concluding chapter.

CONCLUSION

For the analysis model of sustainable information society Braidotti's view can be considered as a queer perspective enhancing the previously cited prism of sustainability in which institutions play a crucial role. In our model we understand gender as a social institution (see Martin, 2004) that as such can change through reflexivity or in other words and putting the concept in the context of IT, through a long-term analysis of the implications of the gender regime in IT innovations.

Thus, we propose the model in Figure 1.

In Figure 1, we can see the interaction between the different levels for the analysis of IT use from the perspective of sustainability considering gender at the third level of analysis. For this approach we need a transdisciplinary view. Sociological and ethnological methods addressing the analysis of gender in its symbolical and structural dimensionality as well as methodologies from consume and economic research and also life-cycle analysis, environmental performance evaluation, etc. must be combined. Thus, also a dialog among disciplines and a reflexivity at the level of the own researches is required. Which also constitutes a crucial step for shaping IT innovations from a sustainable and participatory perspective.

KEY TERMS

Digital Divide: Inequalities between individuals, households, business and geographic areas at different socio-economic and cultural levels with regard to their opportunities to access information and communication technologies (ICTs) and especially the Internet, to the quality of the related resources, to their extent of use and the ability to evaluate the quality of the information and the potential for a wide diversity of uses.

Eco-Development: Harmonization of social and economic objectives with ecologically sound management, in a spirit of solidarity with future generations.

Eco-Feminism: movement that acknowledges a relationship between sexism, racism as well as other social inequalities and the domination of nature.

Strong Sustainability: Perspective (also called "non-sustainability paradigm") conceptualizes natural capital as non-substitutable good.

Sustainability: Ability to make development sustainable to ensure that it meets the needs of the present without compromising the ability of future generations to meet their own needs.

Sustainable Information Society: sustainable developing path for institutions and organisations enabled through information and communication technologies.

Weak Sustainability Perspective: Assumes natural capital to be substitutable through investment in new production forms and consumer goods, from the utilization of non-renewable resources to research on renewable resources.

Gender and IT Professional Work Identity

Mari W. Buche
Michigan Technological University, USA

We need work, and as adults, we find identity and are identified by the work we do. If this is true then we must be very careful about what we choose to do for a living, for what we do is what we will become. (Gini, 1998, p. 707)

Individuals are in a constant state of becoming, of moving between and through various roles and their attached identities and relationships. (Ashforth, 2001, p. 3)

INTRODUCTION

Our daily work is intrinsically tied to our personal image (Alvesson, 2001; Dahlberg, 2004; Gini, 1998). This is particularly true for Americans, since our personal identity is defined by what we do and how we accomplish our tasks (Alvesson, 2001; Gini, 1998). For example, in social gatherings, after learning a person's name, the first piece of information requested is, "What do you do?" Job references provide a wealth of information regarding income, work habits, tasks, levels of responsibility, educational background, etc. Often, the generalizations that people make from this small bit of information are materially incorrect, but that is not usually considered relevant in the social context. It is more important for society to construct a category for placement of the person. In the literature on motivation, Steers and Porter (1991) posit that work primarily impacts individuals in four ways. First, people typically expect to be compensated or rewarded for their efforts (e.g., salary and bonuses). Second, work provides an opportunity for people to interact socially (with some obvious exceptions). Third, employment may influence people's status in the community, outside of the work environment. This is most evident in the case of corporate executives and various professionals. Fourth, "from a psychological standpoint, [work] can be an important source of *identity*, self-esteem, and self-actualization," (Steers & Porter, 1991, p. 574, italics added). Basically, people are internalizing their work experiences. In other words, when workers look in the mirror, what do they see? How would they classify themselves? To what group do they personally relate? Specifically, is there homogeneity in the work identities of IT professionals?

The purpose of this article is to present an overview of the impact of gender on the developmental process of work identity creation in the IT field and its impact on job-related outcomes. This article begins with a general description of work identity in the IT profession, including a review of current literature on the formation of work identities. The next section summarizes research findings on gender from a larger study on work identity in the technology field, providing insights into the effect of gender on job satisfaction and intent to leave. The future trends and conclusion sections provide suggestions and managerial and academic implications.

BACKGROUND

Work identity is not a new concept. However, its application is dynamic and context dependent (Darais, Nelson, Rice, & Buche, 2004; Sveningsson & Alvesson, 2003). Social identity and self-categorization theories provide a theoretical foundation for understanding work identity. Social identity theory states that identity, or identifying with others, produces a feeling of comfort or group acceptance for the members (Hogg & Terry, 2000; Tajfel, 1982; Tajfel & Turner, 1986). According to Ashforth, "Social identification is the perception of oneness with or belongingness to the social category or role," (2001, p. 25). Workers identify with their tasks, responsibilities, co-workers, and organization. Their sense of self is developed through the ongoing process of identification.

Self-categorization theory (Hogg, 1992; Turner, 1987) explains the mechanism of group *prototype*; an ideal candidate made up of a composite of personal and professional characteristics that typifies a member of the target group (Hogg & Terry, 2000). Self-categorization theory asserts that individuals determine their membership in groups based on a mental assessment of similarities and differences with regard to salient features of group composition. In other words, they perceive themselves as more alike than different based on a few key characteristics. These judgments are socially constructed and influence personal behavior. For instance, workers will modify their actions and appearance to better fit into the target population. The familiar "Dress for Success" concept encourages job candidates to conform to the desired group (Molloy, 1988).

When various factors become internalized into a fairly stable concept of self, a work identity has been created. Wallace (2002) defines work identity as "a person's sense of who she or he is, constituted through his or her positioning within the particular relations of power in the workplace" (Du Gay, 1996 in Wallace, 2002, p. 202). She also discusses the influence of managers in creating work identities, deliberately manipulating and influencing employees to adopt particular values and characteristics in the best interests of the organization (Wallace, 2002). Additionally, work identities will change as circumstances change (Sveningsson & Alvesson, 2003; Wallace, 2002, 2003). Wallace (2003) and Sveningsson and Alvesson (2003) discuss the role of management and organizational discourse as contributing elements in the development of work identities. They posit that workers are given or assigned work identities that will either be internalized or resisted by employees. "Internalization refers to the acceptance of influence because it is congruent with a worker's value system and/or because it is intrinsically rewarding," (Steers & Porter, 1991, p. 214). Therefore, if the work identity fits the employees' values and desires, there will be little resistance. Otherwise, the employees will experience decreased job satisfaction, possibly leading to a change in employment.

"Identification, in the generic sense, consists of placing things in terms of systematically related categories," (McCall & Simmons, 1978, p. 62). As researchers, we often classify individuals by gender, religious affiliation, nationality, educational background, etc. Some classifications are changeable and subject to choice, while others are predetermined and fundamentally unchanging. Building on these definitions, it follows that the work identity of IT professionals consists of the categorization of job experiences based on systematically related factors or characteristics intrinsically tied to the work environment (Steers & Porter, 1991).

IT Professional Work Identity is a socially constructed representation of an individual's self-perception of his/her own interactions within the employment environment. (Buche, 2003, p. 11; Darais, Nelson, Rice, & Buche, 2004)

EFFECT OF GENDER ON WORK IDENTITY

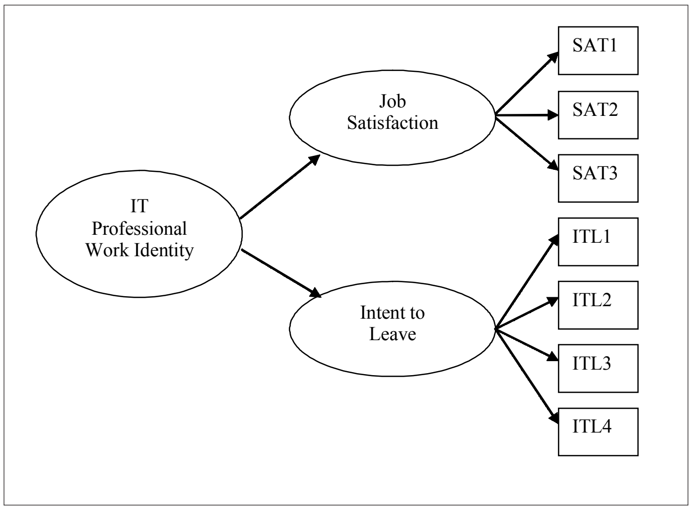
Do women in technology-related occupations consider themselves IT professionals? Or, are they more comfortable being classified as *female* IT professionals? Some research suggests that women in male-dominated fields are reluctant to be classified as *female* engineers (Jorgenson, 2002). Specifically, they object to the homogenous characterization of gender-specific exemplars of a work group identity (Jorgenson, 2002). Gender is not only a physical characteristic, it is also a socially constructed factor instilled through education and exposure. Research suggests that girls and boys are socialized differently through media inputs, education structures, and expectations from influential role models (Bartol, Martin, & Kromkowski, 2003; Gentry, Commuri, & Jun, 2003; Putrevu, 2001). Academic institutions and parents affect female participation in engineering and scientific professions by creating barriers to entry and by lowering expectations of performance in the mathematics and sciences (Wraige, 2004). These negative inputs may become self-fulfilling prophecies, eventually becoming internalized into the females' work identities. Organizations have a great deal of influence in socializing workers (Orser, 1994; Schein, 1988). According to Orser (1994, p. 12), "socialization is concerned with the transmission of beliefs and values from one generation to the next." In businesses, this includes task procedures, organizational policies, and behavioral norms. Each aspect eventually becomes internalized as part of the employee's work identity.

The comparatively few women who pursue engineering and technical careers in spite of these influences are faced with pressures to fit into the male-dominated work culture (Jorgenson, 2002; Melymuka, 2000; Trauth, 2002). Their work identities reflect the same level of professionalism and adherence to the practices and standards of the field. However, they also incorporate features unique to female professionals, such as work-family conflict, motherhood issues, female acceptance in the workplace, and paucity of female role models and mentors (Cukier, Shortt, & Devine, 2002). In addition to differences in the creation of work identities, it is possible that outcomes of work identity on job satisfaction and intention to leave an organization might be different for female employees. Results from a recent empirical study based on 240 survey responses suggest that work identity for female IT professionals is more strongly related to job satisfaction than for their male counterparts (Buche, 2005). Partial Least Squares (PLS Graph version 3.0) was used to analyze the data (Chin & Frye, 2001). Figure 1 shows the model presenting the latent variables and the associations between constructs (Buche, 2003, 2005). Essentially, the analysis indicates that women are less contented at work than males if their individual work identities are not a good fit with the organization. In general, women may choose to stay in their jobs and be miserable, rather than quit. The results of the empirical study reveal a meaningful difference in the influence of work identity on organizational outcomes based on gender (Buche, 2005). This study suggests that managers need to actively monitor job satisfaction and instill a fulfilling and agreeable work identity if they wish to retain productive, experienced female IT professionals (Wallace, 2002).

FUTURE TRENDS

Assuming that organizations make no changes, allowing work-family conflict to continue its assault on female professionals and ignoring the pressures of conflicting expectations, job satisfaction of female IT professionals will likely continue to erode. Worst-case scenario, a subset of employees experiencing lower job satisfaction might choose to exit the IT career field entirely. The current discourse on skills shortage among practitioners highlights the importance of actively changing these dynamics (Cukier et al., 2002; Trauth, 2002; Verton, 2004).

Figure 1. Model of IT professional work identity and outcomes



Note: SAT—Job Satisfaction, ITL—Intent to Leave

Females are a marginalized sector of the IT workforce (Jorgenson, 2002) and require managerial intervention to create a sense of cohesion within the organization. Avoiding discussion on these critical issues does not eliminate their negative impact. Rather, the opposite may occur; ignoring the debate lends support to sustaining an unhealthy and unsatisfying work environment for certain participants. With universities experiencing reduced numbers of students pursuing degrees in technology disciplines (Camp, 1997), corporations need to monitor the satisfaction levels of their workforce. Replacement workers with the desired skill sets will become harder to locate in coming years.

CONCLUSION

Female IT professionals are dedicated and enthusiastic contributors within their organizations. Similar to their male counterparts, their work identities include elements of job characteristics (i.e., skills variety and task significance) and role identity (i.e., technical or general business roles). But, being female in a male-dominated work environment influences their work identities in unique ways (Jorgenson, 2002; Melymuka, 2000). As the results of the research study indicate, work identity for females is more strongly related to job satisfaction than for male IT professionals (Buche, 2005). However, it is not yet known to what extent managers are able to influence work identity development. Future research should investigate this interaction and also the influence of work identity on various organizational outcomes. Also, future studies should include other factors that may have an effect on the outcome variables. For example, possession of highly valued and desirable job skills may also impact intent to leave. The study cited did not control for or include additional variables.

Previous studies have focused on the development of a somewhat static self-image, but current research is looking at work identity as a dynamic process, influenced by organizational changes (Alvesson, 2001; Sveningsson & Alvesson, 2003: Wallace, 2002, 2003). Taking the process model further, understanding work identity as both an emergent construct and as the antecedent of organizational outcomes will enhance management practices. The dynamic nature of the IT field and the pace of change create a situation of uncertainty and anxiety, with workers constantly revising their work identities. Female IT professionals need to be encouraged to remain in the field so that their expertise is not lost. Ideally, a longitudinal study is needed to assess the changes in work identity of this marginalized group over time. Management interventions should be implemented that deliberately promote organizationally sanctioned work identities that also meet the personal requirements of female IT professionals, followed by supervision and impact analysis. Realizing that changes in job-related tasks, resources and equipment, altered reporting structures, modified work practices (i.e., telecommuting), and a transformed client base (both internal and external to the organization) affect employees' work identities in the IT field. A strong alliance between personal and organizational needs can lead to improvement in job satisfaction and reduction in turnover intent.

KEY TERMS

Identity: Reported self-perception of image constructed from various factors.

IT Professional: Someone working in the IT field in any of a number of job positions including programmers, systems analysts, network administrators, help desk technicians, project managers, computer scientists, etc.

IT Professional Work Identity: "A socially constructed representation of an individual's self-perception of his/her own interactions within the employment environment" (Buche, 2003, p. 11; Darais, Nelson, Rice, & Buche, 2004).

Job Characteristics: A model of various key factors that influence a worker's satisfaction and motivation in the workplace (Hackman & Oldham, 1976).

Partial Least Squares: A second-generation multivariate statistical approach to analyze relationships between constructs in a model that contains both observed manifest variables and unobservable latent variables (Chin, 1998).

Role Identity: Organizational expectations of responsibilities and activities.

Second Order Construct: A latent variable created by combining two other latent variables (Chin, 1998).

Self-Categorization Theory: A theory that describes how individuals determine their membership in groups based on a mental assessment of similarities and differences with regard to salient features of group composition (Hogg, 1992; Hogg & Terry, 2000; Turner, 1987).

Skills Variety: The inclusion of many and varied skills to accomplish one's work (Hackman & Oldham, 1976).

Social Identity Theory: A theory that states that identity, or identifying with others, produces a feeling of comfort or group acceptance for the members (Hogg & Terry, 2000; Tajfel, 1982; Tajfel & Turner, 1986).

Socialization: A process that "is concerned with the transmission of beliefs and values from one generation to the next" (Orser, 1994, p. 12).

Task Significance: The perception of value or influence produced by accomplishing one's work (Hackman & Oldham, 1976).

Gender and National IT Policy in Nigeria

Wole Michael Olatokun
University of Ibadan, Nigeria

INTRODUCTION

Information technology (IT) has become a potent force in transforming social, economic and political life globally (Hafkin & Taggart, 2001). Without its incorporation into the information age, there is little chance for countries or regions to develop. More and more concern is being shown about the impact of those left on the other side of the digital divide—the division between the information "haves" and "have nots." Most women within developing countries are in the deepest part of the divide, further removed from the information age than the men whose poverty they share. If access to and use of these technologies is directly linked to social and economic development, then it is imperative to ensure that women in developing countries understand the significance of these technologies and use them. If not, they will become further marginalized from the mainstream of their countries and of the world. It is essential that gender issues be considered early in the process of the introduction of IT in developing countries so that gender concerns can be incorporated from the beginning and not as a corrective afterwards (Hafkin & Taggart, 2001). This article first gives a background to the Nigerian IT policy, followed by a gender analysis of the policy. It points out the gender issues to be incorporated in the policy and the strategies of ensuring women's ability to take advantage of IT. It finally makes recommendations on the way forward for incorporating gender issues in the Nigerian IT policy document.

BACKGROUND

The Nigerian government, in February 2001, formulated a national policy for IT to respond to the emerging global reality. The Federal Executive Council approved the national IT policy in March 2001, and implementation started in April with the establishment of the National Information Technology Development Agency (NITDA), charged with the implementation responsibility. The policy recognized the private sector as the driving engine of the IT sector. NITDA is to enter into strategic alliance, collaboration and joint venture with the private sector for the actualization of the IT vision, which is to make Nigeria an IT-capable country, using IT as an engine for sustainable development and global competitiveness. It is also to be used for education, job creation, wealth creation, poverty eradication and global competitiveness. Analysis of the IT policy document showed that it was comprehensive in scope. It recognizes the private sector as the driving engine of the IT industry (National Policy for Information Technology, 2003).

A sectoral application of IT has been recognized in the formulation of the IT policy, which involves the development of the following areas of the economy:

- Human resource development
- Infrastructure
- Governance
- Research and development
- Health
- Agriculture
- Urban and rural development
- Trade and commerce
- Arts, culture and tourism
- National security and law enforcement
- Fiscal measures and so forth

The National Information Technology Policy (NITP) addressed the various objectives pertaining to these aspects of the economy and the strategies that are to be adopted in applying IT for making these sectors economically sustainable. NITDA's strategies revolve mainly around three major approaches, namely: human resource capacity building, infrastructure capacity building and institutional capacity building.

GENDER ANALYSIS OF NIGERIA'S IT POLICY

According to Zunguze (2003), gender-based analysis is a process that assesses the difference in the impact of proposed and/or existing policies, programs and legislation on women and men. It compares how policy issues affect women and men and analyzes how and why this is so. Gender-based analysis challenges the assumption that policies, programs and legislation affect everyone in the same way, regardless of gender. This is often referred to as "gender-neutral policy." Gender analysis focuses on understanding and documenting the differences in gender roles, activities, needs and opportunities in a given context. It should result in policies, programs and legislation inclusive of women by taking into consideration the existing social imbalances. Gender-based analysis leads to informed policy making and good governance (Zunguze, 2003). Gender role analysis is useful to understanding to what ends men and women utilize Information and Communication Techologies (ICT; i.e., reproductive tasks associated with educating children, productive tasks associated with work, community tasks associated with volunteerism), whether use of ICTs is time-saving, and whether men's and women's time use is different (i.e., does one sex have greater leisure or does increased time flexibility create the potential for more "double shift" as telecommuting blurs distinctions between private (home) and public (work) domains). In Nigeria, the progress towards gender equality is very slow (Olatokun, 2003). This is noticeable in government appointments, students' enrollment in schools, political statements, government commitment to issues that are gender sensitive and so forth. Countless examples exist of political statements that have fallen short because they were not backed by policies. Below we present a gender analysis of the Nigerian IT policy document.

Gender Bias of the Nigerian IT Policy

From the content analysis of the Nigerian IT policy document, the word "women" was mentioned only in three places, namely:

a. Under the General Objectives section on page (iv), the (xiv) objective reads:

   To empower children, women and the disabled by providing special programs for the acquisition of IT skills.

b. So also in Chapter 15, titled, "IT popularization and awareness." In sub-section 15.2, objective (vi) reads:

   To draw on the intrinsic ability of women to propagate positive values within the society at large as an instrument for IT diffusion and promotion.

c. In sub-section 15.3 of the same chapter, objective (v) reads:

   Collaborating with the Ministry of Women Affairs to organize workshops and training in IT skills for women and other special groups.

The above shows that the IT policy relegated gender issues to the background. All through the policy document, gender concerns are not addressed in a way that shows an understanding of power imbalances and gender relations. It makes no attempt to show an understanding or appreciation of gender issues as evidenced in the use of gender-neutral terms throughout the document that seems to assume that by using these terms, it is including everyone, within broader categories of people without recognizing the different contexts, needs or contributions by different sexes.

Also, the policy's vision statement reads:

To make Nigeria an IT-capable country in Africa and a key player in the Information Society by the year 2005, using IT as the engine for sustainable development and global competitiveness.

And the mission statement reads:

To 'USE IT' for: (i) Education (ii) Creation of Wealth (iii) Poverty Eradication (iv) Job Creation and (v) Global Competitiveness.

From the vision and mission statements, the Nigerian IT policy does not have anything relating to gender. Though the vision and mission statements are based on the need to create knowledge in the various sectors of the economy, however, the statements could have been made more gender sensitive by recognizing that a disproportionate majority of the world's poor are women. Not only do too many women lack access to economic and social resources, but they also are too often denied basic human rights.

Though the policy recognized 15 sectors in the Nigerian economy, and addresses the various ministries, it fails to address gender and, in particular, women's concerns in context. In all of the 15 sectors addressed, the word "women" was only mentioned in one; that is, "*IT popularization and awareness,*" where collaboration with the Ministry of Women Affairs in the organization of workshops and training in IT skills for women was mentioned as one of the strategies. In the area of human resource development, which the policy recognized as a critical sector, one would expect that the policy would be very clear on issues of equal opportunity employment and on ensuring that women are accorded the chance of promotion to meaningful decision-making positions. There is provision for IT education at all levels, but there was no mention of how gender issues in the area will be tackled. Also, though the policy explains the government's desire to enhance the physical and faculty capacities of the existing educational institutions to achieve an increase in the numbers of IT professionals, the gender balance of these professionals is not given. It is a known fact that the IT industry is highly sex segregated, and women are found in disproportionately high numbers in the lowest-paid and least-secure jobs (Zunguze, 2003). Research also shows that in training sessions where there is a mixture of men and women, men tend to crowd out women's access to the training required for higher work (Zunguze, 2003). In the strategies spelled out under the human resources development sector, there was no explicit and clear-cut strategy as to how gender issues and concerns would be tackled.

In the sector of arts, culture and tourism, gender issues were also ignored. In Nigeria, cultural laws continue to perpetuate women's lack of access to productive resources by preventing women in rural areas from access to IT resources. Traditional and cultural views remain prevalent and women in Nigeria, as in the rest of Africa, live within patriarchal societies, confined to private spaces. The Nigerian IT Policy could have played a decisive role in addressing the imbalances by regulating women's access to the media, ownership and program content. Few women have been elevated to decision-making positions but more still needs to be done to close the gender gaps. Women's continued limited access to media and information systems are due mainly to their low status in society, traditional and cultural inhibitions, heavy workload compared with men, low purchasing power despite the fact that they work heavily, high illiteracy, absence in positions of formal authority or decision-making and so forth (Zunguze, 2003). The Nigerian IT policy does not recognize these important issues.

In the agricultural sector, the policy recognizes that Nigeria can use IT to reengineer agriculture for the purpose of maximizing food production, improving food self-sufficiency and security, increasing output for industrial raw materials utilization, providing employment and so forth. Thus, employing IT in the reengineering of the agricultural sector includes: food security; introduction of technologies like biotechnology and genetic engineering; aid in environmental monitoring and natural resource assessment; and agro-vision, which involves the use of metrological information with agro-based statistical data to predict the best conditions for exploiting Nigeria's rich agricultural potential. In Nigeria, where the greater percentage of farmers in the rural communities is women, the gender concerns along this line are not addressed. The needs of such women are not mentioned. Finally, in the composition of the Board of NITDA, there was no conscious effort to include gender balance.

Gender Issues to Incorporate into Nigerian IT Policy

Although IT policy and strategy varies considerably from country to country, most policies and policy instruments deal with similar issues. We present some gender issues that should be incorporated in the Nigerian IT policy, as follows. They include, according to Hafkin and Taggart (2001), but are not limited to, the following:

1. **Access and Know-How:** Women's access to ICT is dependent on many factors, such as gender discrimination in jobs and education

systems, social class, illiteracy and geographic location (north/south or urban/rural). As information dynamics accelerate their migration towards the Internet, people without access are bound to suffer greater exclusion. Women need to know how to use the technologies to their advantage. Information relevant to rural women must be disseminated in local languages. More traditional ICTs, such as community radio, audio-visual media and other popular media, should continue to be used, as these are more accessible.

2. **Education, Training and Skills Development:** Illiteracy rates for women in developing countries are far higher than for men. Training methods on ICT usage are often ad hoc and not appropriate to women's needs. These should be made gender sensitive by making them women-specific, ensuring ongoing user support and mentoring in the communities where the women live. Software design must respond to women's needs; for example, using multimedia and interactive CD-ROMs with graphic interfaces for illiterate women and automatic translation software would be more appropriate.
3. **Industry and Labor:** The ICT industry is highly sex segregated. Women are found in disproportionately high numbers in the lowest-paid and least-secure jobs. Research also shows that in training sessions where there is a mixture of men and women, men tend to crowd out women's access to the training required for higher work. Also, research shows that women and girls in IT and engineering tend to be more interested in the social applications of technologies (Keller, 1992; Rathgeber, 1995).
4. **Content and Language:** The dominance of the English language content on the Internet is a major concern raised by women's organizations in the south. Women's viewpoints are not adequately represented, while gender stereotypes (sexism and portrayal of women in media) predominate the World Wide Web (Zunguze, 2003).
5. **Power and Decision-Making:** Women are underrepresented in all ICT decision-making structures, including policy and regulatory institutions, public and private companies. This is because ICT decision-making is regarded as a technical area (typically for male experts), where civil society viewpoints are given little or no space rather than a political domain.
6. **Privacy and Security:** Privacy, security and Internet rights are other important thematic areas for women. This includes having secure online spaces where women feel safe from harassment, freedom of expression, privacy of communication and protection from "electronic snooping." These also include the passage of regulations that can threaten human rights.
7. **Other Issues:** These are listed as follows.
   - Network architecture and deployment (choice of technology)
   - Pricing and tariff issues
   - Licensing issues (ownership and control) (Jorge, 2001)
   - Strengthening technology innovation (research and development)
   - Human resource development for system support
   - IT labor force participation
   - Data infrastructure
   - Facilitating access to IT networks, including universal service obligations.

FUTURE TRENDS

According to Hafkin and Taggart (2001), IT can offer significant opportunities for virtually all girls and women in developing countries, including poor women living in rural areas. However, their ability to take advantage of these opportunities is contingent upon conducive policies, an enabling environment in their countries to extend communications infrastructure to where women live, and increased educational levels. As an indication of the future trends of gender and IT in Nigeria, we recommend in the next section some strategies that could be adopted for ensuring women's ability to take advantage of IT opportunities.

Policy

In Nigeria, as we have demonstrated above, there is already a national IT policy, but without provisions for gender issues. There is, therefore, a need for a deliberate effort to ensure the inclusion of gender concerns in Nigeria's national IT policy. This may take the form of sensitizing gender and development policy makers to IT issues. IT and gender policy makers need to enter a dialog so that IT programs meet the needs of women (Hafkin & Taggart, 2001).

Female Participation in Policy-Making

Greater representation of women in government and other policy-making areas will lead to increased attention to gender issues. Recent *info*Dev research (Chamberlain, 2002; Chamberlain, Hafkin & Huyer, 2002) found that women may not necessarily be gender sensitive. However, in areas where women are discriminated against, such as business, the experience of women will be invaluable for the identification of key action areas. Women may also be better equipped to identify key approaches to skills development.

Infrastructure

Increasing women's access to IT in Nigeria involves increasing availability of communication in areas where women live, since most women in developing countries live in presently underserved areas. Nigerian rural population is between 75%-82% and purely agrarian. Most women live in the rural areas. Thus, extension of infrastructure, particularly wireless and satellite communications, to rural areas and peri-urban areas is crucial to increasing women's access to IT. Emphasis needs to be on common use facilities, such as telecenters, phone shops and other forms of public access in places convenient and accessible to women (Hafkin & Taggart, 2001).

Education

Women represent more than half of Nigeria's population, yet they are denied educational and career opportunities, which are necessary for IT exploitation. If Nigeria wants to compete on a global level, she must nurture and utilize the talents of all women. The single most important factor in improving the ability of girls and women in Nigeria is to take full advantage of the opportunities offered by IT in education at all levels, from literacy through scientific and technological education, which requires interventions at all levels of education.

CONCLUSION

The digital divide is presently at the center of international development concerns (Hafkin & Taggart, 2001). Although most women in Nigeria have had little contact yet with IT, it is clear that there are many opportunities to improve the lives of women and their families. The options offered by IT have to be seized deliberately, because the cost of not doing so is very high. Women in Nigeria need to be given the chance to benefit from the opportunities that IT offer so as to enter the information age. IT is not a panacea for women's problems in Nigeria, since it can bring threats and challenges along with opportunities. However, IT offers many new possibilities that can offer Nigerian women a lifeline for economic, social and political empowerment. Thus, action and complementary activities are pertinent to exploit the options, but it will be worth the effort. Hence, we recommend that there is an urgent need for gender sensitization training of policy makers and state actors to make them aware of specific issues related to IT impact on women and that gender should be mainstreamed in all priority sectors addressed in the IT policy. Finally, there should be provision for a "gender and IT" sector in the policy, with concrete strategies about how to bridge the digital divide between men and women. It is hoped that the digital divide will no doubt be bridged provided these recommendations are followed.

KEY TERMS

Digital Divide: Disparities/differences based on economic status, gender, race, physical abilities and geographic location between those who have or do not have access to information, the Internet and other information technologies and services, and the skills, knowledge and abilities to use information, the Internet and other technologies (ALA, 2000).

Gender: The fact or condition of being a male or a female human being, especially with regard to how this affects or determines a person's self-image, social status, goals and so forth.

Gender Analysis: Gender analysis focuses on understanding the differences in gender roles, activities, needs and opportunities in a given context.

Gender Gap: The apparent disparity between men and women in values, attitudes, voting patterns and so forth.

Information Technology: Encompasses all forms of technology used in processing and disseminating information.

Information Technology Policy: Policy guidelines that concern all forms of technology used in processing and disseminating information.

Policy: A course of action developed for the achievement of a set of goals.

Women: A woman is a female human being as contrasted to a man, an adult male. The term woman is used to indicate biological sex distinctions, cultural gender role distinctions or both.

Gender and Professionalisation in IT Fields

Esther Ruiz Ben
Technische Universität Berlin, Germany

GENDER AND THE EVOLUTION OF IT PROFESSIONS

From a historical point of view, IT professions have their origin in increasing computerisation, especially in the insurance and banking businesses. This stimulated a rise in demand for highly qualified programmers with the ability to take into account the economic side of business gains during the 60s[1]. To satisfy the need for such qualified people, computer science was institutionalised in universities in the 70s. The newly emerging software enterprises, mostly from the U.S., occupied the fields formally served by hardware enterprises and played a crucial role in the development of the IT industry. This included the development of new organisational cultures that were less hierarchically oriented. Moreover, the expansion of the sector and creation of new jobs enlarged the jurisdictional fields of work for software developers. At this stage in the evolution of IT professionalisation, we can find many optimistic views stating that new computing areas would be gender-neutral spaces that provided opportunities for women's participation (Deakin, 1984). Nevertheless, as Griffiths (1988, p. 145) pointed out at the end of the eighties, within a decade computers had been appropriated by men.

With the Internet boom of the 1990s, the sector became even more diversified in its jurisdictional fields, which hindered an institutionalisation of career paths and professionalisation[2]. New occupations arose alongside the technological progress in the information and communication industries. This brought about structural changes that influenced the development of professional groups: First, there was a common dynamic of innovation processes in the IT branch." This was followed by increasing standardisation processes in the working fields and an essential erosion of jurisdictional constancy within the professional groups (Baukrowitz & Boes, 2000). Moreover, the jurisdictional fields for computer scientists, especially the field of application development, were not yet totally monopolised by any particular group because there was "no undisputed dominance of information technological knowledge" (Hartmann, 1995, p. 164). Thus to a large extent, the failure to restrict the jurisdictional fields of computer science is the reason for "the low professionalisation" of the sector (Rothenwald, 2001, p. 17).

From a gender perspective, the first question that arises here is how women participate in this particular development of the IT professions. From a historical perspective, Kritzer points out that the so-called semi-professions (those without a recognized and institutionalised corpus of expertise) have been the main area of women's paid work, while the professions have been male-dominated (Kritzer, 1999). Connected to this division of work, we can also observe a horizontal gender segregation of professions with implications for the inclusion/exclusion of men and women from certain professional areas irrespective of task attributes that correspond to stereotyping in male or female terms. In this sense, Witz (1990, p. 675) refers to "professionalisation projects." Nevertheless, these projects also change over time. Gatta and Ross (2002) point out that changing societal expectations of men's and women's roles, changing skill mixes, declining discrimination, and reduced male resistance to women's entry into work influences the increase of women's presence in traditionally male occupations and also alters employers' expectations.

As we can see from historical discussions of computer science[3], women have always been involved in computing and mathematics. Nevertheless, several authors have shown that women are concentrated in those IT occupation areas with the poorest employment conditions, whereas men are overrepresented in fields that are more valued, such as technical management, systems analysis, and programming (Ruiz Ben, 2003; Webster, 1996; Webster & Valenduc, 2003; Woodfield, 2000). The question arising here involves the extent to which the professionalisation process of IT occupations represents an opportunity for women to play an active role in the innovation paths of the information society, as well as the gendering or de-gendering practices linked to this process. Our aim in this chapter is to provide an overview of the scholarly literature in the social sciences on the debate about gender and professionalisation in IT fields and sort through the current discussion about the professionalisation of software development in Germany. We present evidence for the gender segregation in IT professions and discuss the key issues that have been addressed by the empirical literature.

BACKGROUND

According to Abbott (1988), professionalisation refers to the expertization of work and the struggles over jurisdictions of expert work. When such jurisdictions become vacant, professions develop and groups of expert workers can convert their work and knowledge into a currency. Particularly abstract knowledge systems are the main currency basis for inter-professional struggle according to Abbott. In IT fields, there is no well-established definition of IT professions, as international reports have stated (Deiss, 2002). As a consequence, the spectrum of existing studies reveals significant variations in the definitions of IT professions, according to the scope of each study and the motivations of its authors (Webster & Valenduc, 2003). Common for the whole IT industry are several factors related to the transformation of work practices: high personal implication; increasing involvement with customers; personal responsibility for continuous training; the need for continuous upgrading of employability; flexibility in work time and location; unpredictable work rhythms, and so forth (Webster & Valenduc, 2003). Moreover, innovation sources and the knowledge systems operating in this industry are highly diverse and increasingly demand soft-skills, which are linked to gender stereotypes. However, some research has shown the persistence of gender bias in the professionalisation process of IT occupations (Huws, 2003; Huber, Reiff, Ruiz Ben, & Schinzel, 2001; Ruiz Ben, 2002, 2003, 2005; Wacjman, 2002; Webster, 1996; Webster & Valenduc 2003).

The explanations for the causes of gender inequalities in the professionalisation process of computing fields cannot be reduced to a simple view of gender constructions. A set of factors lead to the persistence of the gender gap in IT professions, as Webster and Valenduc (2003) note: "time constraints, unequal sharing of housework and children and elderly care, constitution of the harmonisation of the family and professional life as mainly an individual and female problem, total availability model, male environment, low access to training, one way flexibility, under valuation of women's competences and skills." (p. 144) The culture of professional IT engineers is marked by a shared pleasure of both skills: hands-on competence in tinkering, and the abstract competence in logical, analytical problem solving in engineers and software developers' circles (Faulkner, 2000), which results in developing an exclusive, informal culture and professional habits. Software specialists (with men in the majority) build their identities in this cultural context, bridging their early socialisation practices with their professional practices. However, their socialisation differs from that of women, as does their professional motivation in software development (Faulkner, 2000).

This represents the main line of argumentation for explaining the gender gap in computing professions. It emphasizes the correspondence between the gender divide and the social/technical divide, or the division in computing between the physical and the social realms on the one side and the technical realms on the other (Faulkner, 2000; Woodfield, 2000). Nonetheless, from the perspective of the demand for labour, the growing presence of workers with hybrid qualifications indicates that qualification in computer science is not a general guarantee for entering the IT labour market. As Müller (2000) argues, "The association between qualification and career advancement legitimates the meritocratic ideology of organisations. This renders the gender difference as a structure of discrimination 'objectively' obsolete" (p. 20). Moreover, within organisations, several factors support this ideology, such as specialisation or the increasing development of informal structures[4].

On the other hand, according to the actual organisation restructuring Halford and Leonard (1998) argue that personal identities as well as the performance aspects of the employees are redefined. This means that traditional gender regimes in organisations are destabilised by the breakdown of rationalisation. One example of change in IT organisations is the increased value placed on diversity in industrial production. This transformation entails an intensified search for innovative strategies and is increasingly considered in many software firms. It has expanded in the sector because the integration of a spectrum of diverse perspectives augments the probability of accepting innovative products. Related to this, we can observe the heightened importance of aspects such as requirements analysis, usability, and teamwork in the software development. Thus, we can conclude that structural conditions regarding working practices and institutional support, as well as cultural factors influencing the definition of expertise within organisations and in everyday practices to a large extent determine the gendering processes of IT professional projects. Professionalisation theories can serve as a basis for analysing the combined effects of the factors mentioned above from a long-term perspective without leaving aside the importance of current practices within organisations particularly the mutually determined construction of technology and gender meanings. In the next section, we present this perspective in more depth.

PROFESSIONALISATION AND GENDER IN THE GERMAN IT SECTOR

Drawing on professionalisation theory from a gendered perspective, the main goal of our study is to analyse the strategies of monopolisation of software development as a profession, (i.e., its demarcation and enclosure in terms of qualification requirements and delimitation of related areas of expertise), in order to reconstruct the meaning of gender in this process. The two main research questions in our study are: (1) What are the main characteristics of the professionalisation process of software development in Germany? and (2) What are the opportunities for women to enter in this professionalisation process? To answer these questions we take into account the influences of academia, the practice of software development and professional associations, as well as of the state. We have considered the perspectives of IT-specialists working in the practice of software development and also of those actors who decide on the entry of new professionals into the practice of software development in the professional arena, (i.e., personnel managers in software enterprises). Considered as the main source of professional qualification for the practice, we have included the self-definitions of computer science from the perspective of the academic core. The empirical basis of the study is based on open interviews with professors of computer science (6), personal managers (14), and software developers (29) in software enterprises. Regarding the characteristics of the enterprises, we chose a balanced number of software companies in different sectors of software development and of varying size. The interviews were conducted between the end of 2000 and 2001.

Our results show that computer science as a discipline is widely recognized in the academic arena and also supported by a large professional work organisation[5], which is also linked to the IT industry. However, the discipline does not have an extended, recognized knowledge monopoly in the IT industry, neither a moderator nor an integrative role in the heterogeneous area of IT. In large enterprises, qualification demands are higher and more specialized, reflecting a more accurate division of work and a clearer delimitation between "technical/social" areas. Here we can observe some professionalisation patterns supporting a kind of jurisdictional stability in software development. Hence, there are concrete qualification demands, internal training, and institutional supports (professional associations, trade unions). Bolstering this development, application areas, located in most medium and small size companies in the German IT industry, undertake the risk to adapt software products to concrete customers' needs in the short-term. This also entails personal risks from the perspective of the work force with time constraints tied to projects, a non-stop availability model, one way flexibility, low access to training and no support for balancing family and professional life, which means workers assume responsibility for their own family and old-age care. How is gendering embedded in this particular professionalisation path of software development? On the one hand, we can observe different gender segregation models that correspond to the different working conditions in larger organisations and in medium- and small-size enterprises. On the other hand, definitions of tasks as technical *in* IT fields serve as a fluid demarcation line or, in the terms of Bourdieu and Wacquandt (1992), a source of distinction that genders working areas throughout the IT industry. This definitions are a crucial basis for building symbolic knowledge systems and with it, professional jurisdictions as described in Abbott (1988).

In large enterprises, in which working conditions are more favourable in terms of working time options or integrated programs for balancing family and professional life, women very often work in tasks coded as socially oriented, such as program or quality management even though they have a qualification background in mathematics or computer science. Technical areas remain a male domain. This horizontal segregation is supported through the adaptation of the mutually reinforcing gendered expectations of personnel managers and workers. In smaller enterprises, in which time pressure and working conditions are worse, young women without family responsibilities in particular find work chances in areas such as consulting or design. Areas defined as "technical"—although with a very diffuse and changing definition—remain also in enterprises of this size a masculine domain.

In sum, cultural habits linked to the construction of technical meanings and jurisdictions in IT organisations contribute to gender segregation and are reinforced by structural factors such as the lack of resources invested to support a balance between family and professional life. Nevertheless, some cultural changes exist within software development practices aimed at getting closer to customers' needs and also influenced through the internationalisation of the IT industry. As we explain in the next section, these changes may create increased opportunities for the participation of women in the professionalisation project.

FUTURE PROFESSIONALISATION TRENDS: CHANCES FOR WOMEN'S ENROLLMENT

The desire to understand and translate customers' needs into software products has increased the importance of social aspects in software development. Parallel to this, those areas that can rapidly standardise their production processes can easily move to other countries. This has spurred a cultural change in the IT industry, particularly in large enterprises, which are placing more and more value on diversity. Offshore practices in the IT industry bring changes in the definition of technical areas and tasks. Taking into account that technical tasks are easier to standardise and to offshore as those linked to requirements analysis, we could argue that the connotations of prestige in technical areas will also change. Windows of opportunity open for the participation of women in the professionalisation process of IT fields not only in western countries, but in developing countries[6] building regional stratified clusters or influence areas (i.e., India, Latin-America, South-Asia). Parallel to this we observe inclusion/exclusion forms of workers in/from IT fields interacting with contextual differentiation and categorisation patterns (gender, social stratification, race, age)[7]. Nevertheless the particular occupational segregation linked to gender and to the internationalisation process of IT fields remain a black box. Further research is needed to analyze the consolidation patterns of prestige areas in IT or, in other words, how decision fields in software development, those jurisdictions closer to power, become monopolized and gendered.

CONCLUSION

What characterizes professionalisation in IT fields in Germany? Demarcation of particular areas for high-qualified technical specialist correlates with other exclusionary factors, for example, qualification or lifelong training, which is essential for continued participation and promotion in the IT branch. Employees do not receive equal guarantees in investment in in-service training (Berndes, Kornwachs, and Lünstroth 2002) and particularly in small- and mid-size software companies, continuous training is an individual matter. Corresponding to new post-Fordist forms of work (adaptation to constantly changing demands, increasing self-responsibility, availability), the present creed of flexibility in the IT sector—mainly in smaller companies—turns out to mask differentiation processes which develop in relation to the employees' gender, age, qualification, and personal circumstances. What are the opportunities for women to participate in this process? Gendering (linked to other categorisation factors such as age, qualification, and familial situation) is embedded in the professionalisation project of software development. The compatibility of family and working life seems to become superfluous following the logic of the persisting model of the male breadwinner. Acker (2002, p. 317) concludes: *"*With the new economy, which grants some women access, a new hegemonic concept of masculinity is developed, just as there is a factual male dominance in the fields of information technologies, computers and financing*"*. From the perspective of the professionalisation of software development in some areas of the IT branch and considering the necessary integration of "social" and "technical" areas, women are theoretically in a very advantageous position. However, contradictory impulses are discernible when it comes to creating strategies for avoiding the femininisation of the profession: the emphasis on the priority of formal-technical skills (and time disposition, since they form part of the competent impression) and the naturalisation of social skills in order to protect men from such demands. Escape routes for the retention of a "male profession" are thus conceivable and realistic—developers (predominantly male) receive additional in-service training, which means that these skills are building a symbolic knowledge system parallel to the professionalisation of particular areas of software development especially in larger companies. This leaves the professionalisation process of software development open and fluid in many areas, as well as the technical connotations used as "distinction lines" for gendering. The open question regarding IT is how expertise related to the social skills coded as feminine in areas such as project and quality management—crucial in the future development of the IT industry—are being culturalized and achieve the status of "currency". And moreover, who are the people who monopolize and will continue to monopolize this "currency".

KEY TERMS

IT Fields (Information and Technology Fields): Professional and occupational areas of work related to the production and selling of information technologies.

Occupation: Principal work by which one earns one's livelihood.

Offshore: Building of dedicated captive centers by a company in remote, lower-cost locations.

Profession: Knowledge based occupations achieved following standard periods of higher education and/or vocational training.

Professional Work Organisations: Administrations or companies with strong collegial control that claim for professionalism.

Professionalisation: Struggles over jurisdictions or demarcated areas of expert work that result in the expertisation and monopolization of work.

Professionalism: Occupational control and definition of work including educational standards.

Gender and Software Engineering

Edeltraud Hanappi-Egger
Vienna University of Economics and Business Administration, Austria

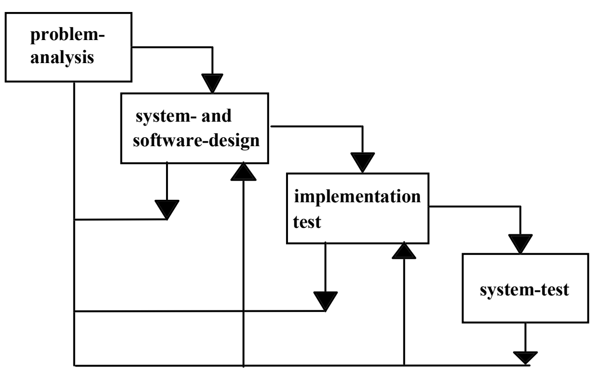
HISTORICAL BACKGROUND

The history of software engineering is not very long, but rather intensive. In the beginning of the 40s, programming was seen mainly as manual, electronic engineering job, done by women, in particular mathematicians (compare e.g., Schinzel and Zimmer, 1998). Changing more and more to an intellectual, mathematical, high status task programming started to be male-coded and remained to be done by men.

The first computer systems were developed for military purposes. The end products seemed to be not adequate to the expectations of the users. Most system engineers did not care about the users' needs, nor did they consider any kind of documenting their own thoughts and works as being necessary. This led to the so-called "software-crisis" in the sixties and raised the discussion of adequate–in terms of more structured and more transparent—methods in software engineering. One important result of this discourse was the classical "waterfall model" (see Figure 1).

Software development is seen as sequence of single phases. The output of the preceding phase delivers the input to the proceeding phase, returning to a former state is in principle possible, but there is also a point of no return caused by cost constraints. Generally, this approach considers system development as step-by-step procedure without iteration, only small punctual adaption should be done. User-involvement is often limited to the first phase, namely to the problem analysis. In order to define the functions of the computer systems the users have to serve as information source, describing the current working process, and formulating system requirements. The underlying engineering perspective clearly makes it to the designers' task to come up with a technological solution. The contact with users is limited to the first step when specifying the functionality of the system and the to the last step when the system is delivered.

Figure 1. The waterfall model

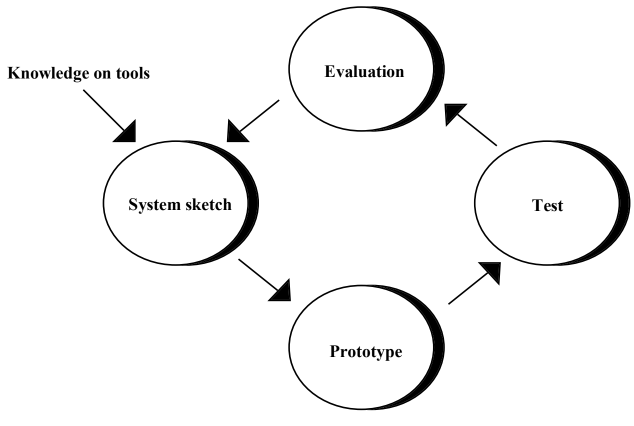


This treatment of system design and development still lead to inadequate products and as a consequence more attention to the users' needs was necessary. In particular, in the growing commercial and non-military application fields it became clear that there must be a stronger cooperation of engineers and people from the concerned organizations.

The new "socio-technical system approach" stresses the relation of human aspects and computer aspects trying to find an optimal "fit" for both (Mumford, 1971). Contrary to the purely "engineering" perspective, it has become accepted that social dynamics play a crucial role in the design and development procedure. Consequently new methods of system design integrating social aspects have been developed. In particular, the communication problem between users and engineers was identified as main source for badly specified systems. Thus, the involvement of the users during the whole system design—and development process became a necessity—this was the birth of (e.g., the idea of participatory design) (Floyd & Keil-Slawik, 1983) and of methods called "prototyping" (see Figure 2.

In the literature, there are some different models (e.g., incremental model, spiral model, etc.), which do have the same basic ideas of the prototyping approach: the iterative involvement of the future users of a system. A system sketch, a main kernel is implemented in cooperation with the users. After a

Figure 2. The prototyping approach



testing phase with users (which is supervised by system-experts or tutors), the evaluation of the first prototype will lead to a step-by-step extension of the system.

Besides communication features this approach requires a new understanding of system design: Computer scientists are not the experts from the application field. Consequently, they have to cooperate with people actually working in the according environments.

In the last decades, this approach of considering software engineering as organizational modeling was further developed. It became clear that system development is organizational development (compare e.g., Briefs, Ciborra, & Schneider, 1983; Kling, 1984). The design and introduction of a computer system imply changes in the organizational structure and organizational aspects strongly determine the design and specification of technological systems.

Summarized it can be stated that in the last decades the view on system development changed a lot. Users were more and more involved—ranging from pure observation at the beginning of structured system design to contemporary user-centered design methods (see also Kuala, 2003). In particular, the view that computer system design is organizational design implies many decision-making competencies of the users. Thus, it could be stated that there is a new understanding of constructing technological artifacts leaving the path of "objective" modeling following the view of "negotiated constructions." The development context in terms of who is involved, which competences do these people have, which budget and time constraints play a role and the like influences the shape and function of systems. Consequently the process of system design is embedded in social settings and therefore always very specific (see also Hanappi-Egger, 1998, 2000). The author demonstrated this with computer science students: All students got the same task of programming software systems. At the end of the semester, there were as many (different) solutions as development teams.

The next question immediately is if system design is the result of social processes, which role plays "gender?" In other words, if the participants of system design are "gendered," how does this influence the design and development of software systems?

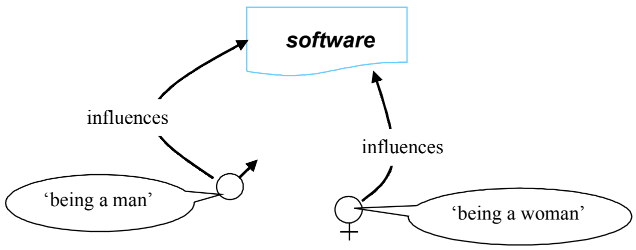
THE ROLE OF GENDER IN SOFTWARE ENGINEERING

From an organizational point of view, there are specific gender patterns and gender relations structuring organizations and consequently the social interactions. In other words, "sex" is associated with social constructions of gender roles and behavioral expectations. Biologically identified "women" are more likely expected to be feminine and men are expected to be masculine. This social mechanism tries to match the biological and the social gender of human beings. At the same time there is a gender hierarchy subordinating "female" coded activities and capabilities. West and Zimmerman (1998) call this "doing gender" referring to the fact that there are processes in organizations, taking place producing and reproducing gender relations (see also Hanappi-Egger, 2003).

Combining the two approaches, namely that gender plays a crucial role in social settings in general and that system development is a social activity (as presented in the historical overview) leads to the statement that gender has to play a role in the design and development of technological artifacts, too (for a general discussion see Hanappi-Egger, 2003).

In order to elaborate this statement, an analogy to the built environment can be drawn: From a design perspective in the built environment Kennedy (1981, p. 76) exemplifies gender-specifics in architectural practice: The female principles consists of more

Figure 3. Gendered design based on biological gender



user-oriented, more ergonomic, more functional, more flexible, more organically ordered, more holistic/complex, more social, more slowly growing. The male principles are designer oriented, large scale/monumental, formal, fixed, abstractly systemized, specialized/one-dimensional, profit-oriented, and quickly constructed. Wajcman (2001) doubts this approach since there are many intra-gender differences and several "male" characteristics are rather caused by commercial imperatives than by biological gender of the designers. Nevertheless, she establishes the connection between the built environment and patriarchy and shows that it is mainly the (shared) cultural assumptions on gender roles (such as gender-specific division of labor) which shape the design and development of objects[1].

A similar reflection will be made in the following for computer-systems:

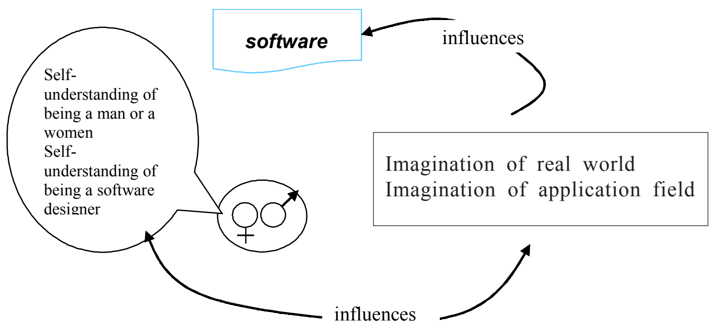
One main critique on the development of technological artifacts is the male dominance. Mainly men are designing and developing systems. Consequently, it is assumed that a very specific—namely male—perspective is implemented. The stronger involvement of female engineers should lead to more diversified perspectives and consequently to "better" solutions.

Evidently, this approach is based on a rather biological understanding of gender. Men as such and women as such do have different perspectives useful for the design of technologies. This essential view neglects the role of professional socialization: As several scholars (e.g., Rommes, Oost, & Oudshoorn, 1998) mention there is no empirical evidence that women design systems differently. Hanappi-Egger (2004a) stresses the importance of hegemonic ways of perceiving problems in computer science educations and thus leading to a rather homogenous self-understanding of both male and female computer scientists. In other words female engineers often do share more with male engineers as (e.g., with female social scientists). On the other side, it has to be noted that women often leave the technical field after some time due to their unwillingness to adapt to the heavily male coded professional culture. Thus, the "main stream" in engineering is "male stream." Attributes such as "fascinated from technology, anti-communicative, freaky, anti-social" and the like are gendered codes linked with people working in the technological field. In addition, as it is evident, these are male codes. The effort to increase the number of females in computer science can be positioned into the liberal feminist perspectives, since basically the organizational settings and systems are not questioned. Women have to adapt to the given circumstances and they have to be trained in being self-confident. Consequently, this view often is called the deficit-oriented approach identifying women's deficits as the crucial reason for the under-representation of women.

The importance of efforts bringing more women into the field of technology shall not be de-valuated. Nevertheless, one has to keep in mind that implicitly the "gender" issue is strongly connected with being a woman in a male-dominated field. Only little attention is paid to the fact that gender issues concern men, too, in terms of hegemonic gender patterns described in the already mentioned terms of being freaky and fascinated by technology or being a hacker.

As soon as this essential approach is questioned, one has to face that it is not so much the biological determinism of gender playing a crucial role in the design of systems, but it is the socially constructed way of perceiving gender and gendered processes. Studies of the development of information technologies, for example, indicate that design practices are dominated by the so-called "I-methodology" in which innovators consider their own preferences and skills to be representative of those of the future user (Akrich, 1995). The deconstruction of technological artifacts shows a gender-bias in the design of technologies: workflow management systems incorporate a specific view of division of labor in which "female" tasks are heavily forgotten or taken as irrelevant. The hidden social mechanism

Figure 4. Gender scripts-based design



leading to this phenomenon can be explained by the Figure 4.

As Akrich (1995) has suggested, "innovators are from the very start constantly interested in their future users. They construct many different representations of these users, and objectify these representations in technological choices" (Akrich, 1995, p. 168). As a result, technologies contain scripts: These scripts determine the way future users are seen, which rights, competences and skill are anticipated and consequently realized. Since these scripts reveal a gendered pattern, it can be assumed that gender scripts in terms of self-understanding to be a man or a woman but also the self-understanding of being a software designer and its gendered codifying are incorporated into the technological artifacts. This means that designers and developers as social entities have (often unconscious) gendered perspectives approaching the settings they are going to model in a software system. Consequently, they represent also their gendered imagination of the real world as well as of the application field and incorporate those in software systems.

Even though this perspective stresses the importance of gender scripts as part of social settings, it still sticks to a view that gender is an attribute, something people "are."

Recent gender studies focus less on the bodily difference, but more on the ways of ascribing gendered images to them. Consequently the focus of interest is on "doing gender." With respect to this gender, is a dynamic producing and reproducing gendered understandings in social interactions. It is an essential part in social settings and cannot be avoided, but the way of constructing gendered meaning can be reflected on. This leads to the necessity of questioning gender scripts and their incorporation in the design and development of artifacts. Hanappi-Egger (2004) calls this "triple loop learning." In other words, system development has to be put in the social setting and vice versa and requires a gender diversity-related approach: Gender diversity refers to multiple identification aspects and tries to overcome gender-dualism as well as exclusion mechanisms based on social categories such as gender, sexual orientation, age, ethnicity, and the like. Instead, contextual dynamics are seen as driving force in system design and development. In other words, a new approach to software engineering has to be developed which will be sketched in the following.

BREAKING CONVENTIONS: GENDER DIVERSITY IN SOFTWARE ENGINEERING – FROM SINGLE TO TRIPLE LOOP LEARNING

In order to make the hidden assumptions on the social setting of system designers visible, the reflection on assumptions made a-priori is important. Hanappi-Egger (2004) calls this "triple loop learning" based on the idea of Flood and Romm (1996). Flood et al. (1996) described triple-loop learning as a cyclic process consisting of three loops: The first loop (the How? loop) is built around the question "Are we doing things right?" The second loop (the What? loop) is built around the question "Are we doing the right things?" The third loop (the Why?

loop) is built around the question "Is rightness buttressed by mightiness and vice versa?"

Concerning software engineering processes, these three loops can be assigned to the following steps:

- **Single-Loop Learning:** Questioning the functionality (doing things right)
- **Double-Loop Learning:** Questioning the specification (doing the right things)
- **Triple-Loop Learning:** Questioning the mental models and scripts

Step one (single-loop learning) and step two (double-loop learning) are well-established activities in system development. Proofing functionality and the adequateness of the specification are no trivial tasks, but they are accepted as essential parts in the development processes. Much effort is put on the attempt to grant correctness in syntax as well as in semantic. Step three (the triple-loop) is not yet part of system development, but is necessary to prevent the implementation of very specific and exclusive perspectives on the underlying social framework.

In order to make these hidden assumptions visible, the third learning step is necessary to open up a space for discourse. From the perspective of the social shaping of technology we have to add this crucial learning loop in the design and development process: In terms of system engineering this means that besides developing the system, a meta-level has to be established allowing participants to reflect on mental models, on assumptions and in particular on their scripts influencing the way of specifying the system. So the questions to be discussed are: How does it come that we came up with this specific specification? Which assumptions concerning social relations in terms of division of work, power, and communication have we made? How has our self-understanding determined the system specification?

Clearly, this opens up a methodological problem. How can this third learning loop be induced? The deconstructive approach of the author which is currently part of a forthcoming research project is called "mind scripting": Based on the so-called memory work of Frigga Haug (2001), a German social scientist, system developers are asked to write texts related to a specific topic within their work setting (such as "quality" or "modeling").

The presumption of this method is that individuals appropriate social, organizational, and professional formative contexts and interpret, transform, select and reconstruct reality according to the mental models acquired within this process. These mental models are not only individually shaped but are also collectively shared constructions of reality. Consequently, deconstructing and comparing written texts, which can be read as contextual, selective, and temporal representations of the writer, can be used as source for making mental models and their gendered dimensions visible. "Mind scripting" in an innovative method, because:

- It really allows for deconstructing the hidden and unconscious imaginations by asking for a piece of memory such as "Last time when I had a team-meeting in the software development project"
- Since the texts are written in a third person, it is anonymous and allows for "objectified" analysis and discussion
- Deconstruction is done by putting questions such as "How does the author describe him/herself? Which other men or women appear in the text and how are they described? Where are ambiguities, contradictions, and jumps?" and also questions such as "Which causalities does the author construct? Which links are assumed"
- The comparison of the texts highlights similarities and differences, so shared views and perspectives can be identified

With respect to software engineering and gender, this means that mind scripting can be used to make the mental gendered maps of system developers visible. The according texts can be linked to their professional (gendered) self-understanding. The analyses of these texts within a development team may serve as source for discussing pre-assumptions, stereotypes, ways of thinking, but also to discuss which approaches are excluded and neglected.

Clearly, there is further research needed in order to elaborate the concept of gender-inclusive software engineering, in particular to come up with new methods of designing and developing technological systems.

KEY TERMS

Gendered Patterns: Hegemonic behavior in terms of gendered codes such as masculinity and femininity.

Mind Scripting: Deconstructing textual pieces of memory.

Model: A reduced representation of real world settings.

Participative System Development: The design and development of systems involving the users' perspectives.

Prototyping: An iterative process to develop a first version of a system serving either as starting point or as specification for the end product.

Scripts: Mental references of social settings and expected behavior.

Software Engineering: The discipline devoted to the design and development of a software system.

System Specification: Determination of requirements and functions of a system.

Technological Artifact: Technological objects understood as result of construction.

Triple-Loop Learning: Model of learning with at least three feedback loops concerning questions such as "doing the right things," "doing things right" and "how does it come that we decided to do these specific things."

ENDNOTE

[1] As an example, the design of houses and their rooms can be taken: Usually men and kids have private rooms (such as own bedrooms or working room), while women often have only rooms to be shared with others.

Gender and Telework in Information Technology[1]

Donald D. Davis
Old Dominion University, USA

Katherine A. Selgrade
Old Dominion University, USA

Debra A. Major
Old Dominion University, USA

INTRODUCTION AND BACKGROUND

Information technology (IT) work is often distributed geographically through practices such as teleworking. Telework lends itself well to IT workers because they work easily with information technology, which is required for telework, and because many IT jobs consist of knowledge work—the creation and analysis of symbols and ideas—which may be done anywhere and anytime.

Advances in information technology make distributed work possible. Globalization and the need for organization flexibility make distributed work necessary (Davis, 1995). Organizations distribute work to take advantage of scarce and inexpensive talent, enhance innovation and product design, and to reduce real estate costs, development time, and labor costs. Workers choose distributed work to balance work and life demands, reduce commuting time, accommodate disabilities, and take advantage of distant opportunities. Telework, a form of distributed work first described by Nilles (1975), has established itself throughout the United States. We discuss telework trends and provide some data describing teleworkers in IT professions in the United States.

Four forms of telework are commonly used (see Key Terms; Bailey & Kurland, 2002; Kurland & Bailey, 1999). Most teleworkers use a combination of these forms, although home-based telework is most prevalent (Davis & Polonko, 2001). Each form of telework is practiced for different reasons and produces different work experiences and outcomes (Bailey & Kurland, 2002; Davis & Polonko, 2003; Helling, 2000).

A national survey of telework practices in the United States was conducted in 2001 under sponsorship of the International Telework Association and Council (ITAC) and AT&T (Davis & Polonko, 2001). The sample was stratified to represent all U.S. households and was diverse with respect to gender, ethnicity, occupation, organization size, and industry. Results showed that there are approximately twenty-eight million teleworkers in the U.S. Compared to nonteleworkers, teleworkers are significantly more likely to be from the Northeast and West, male (54% of teleworkers), have higher education and income, work in professional/managerial occupations, work in industries such as construction, professional/scientific/technical services, health care/social assistance, and work in very small and very large organizations. There were no significant differences in telework practice for marital status, race/ethnicity, and age.

Davis and Polonko (2001) report several findings concerning telework and its impact on ability to balance work and family demands that are relevant to IT professionals. Teleworkers, especially those who work at home, are more likely than nonteleworkers to report working longer hours and that the demands of their personal life take time away from their work. They also report more difficulty relaxing at home when doing non-work related activities. However, teleworkers are also more likely to state that their family members and friends report less unhappiness with the amount of time they spend working at home, report that their home life is less likely to prevent them from working the amount of time they want to work at home, and that working at home interferes less with other activities in their personal life. These differences suggest that teleworkers may be better able to manage the time they spend working at home compared to nonteleworkers. While teleworkers may experience some personal costs, such as difficulty relaxing, they experience significant benefits compared to nonteleworkers in terms of less interference between work and family roles. Women may particularly benefit from telework because they are often responsible for childcare.

Research examining women teleworkers shows mixed benefits. Women teleworkers may experience less stress because they have more control over their time, do less commuting, experience fewer distractions, and are available to their families during the day (Kraut, 1988; Olson & Primps, 1984). On the other hand, women teleworkers may also experience greater stress due to reduced separation between work and family obligations resulting from bringing the workplace into the home (Olson & Primps, 1984). All teleworkers report working more hours (Davis & Polonko, 2001; Mirchandani, 1998).

Men and women adapt differently to work at home. For example, the time saved by reduced commuting gets used differently; women tend to use this time to do household chores, whereas men use this time to do more job-related work (Steward, 2000). Both men and women maintain a separation between work and family, but they do so for different reasons. Mirchandani (1999) reports that most women state that they separate work and family to reduce the stress of simultaneously attending to work and family obligations, whereas no men report such reasoning. She adds, "For women, the home is not a place of nonwork, but rather another workplace" (p. 92). Women teleworkers, especially those with children, may experience more difficulty in balancing work and family life than men (and women without children). Yet women claim to choose to telework as a means for balancing work and family obligations (Beasley, Lomo-David, & Seubert, 2001).

TELEWORK IN IT ORGANIZATIONS

Telework may be easier for IT workers due to the knowledge content of their work and their facility with using technology, although research results are mixed. A study of IBM teleworkers and nonteleworkers showed no difference in work family balance (Hill, Hawkins, & Miller, 1996; Hill, Miller, Weiner, & Colihan, 1999). In participant interviews, many claimed that teleworking helped them fulfill family obligations and strengthen family relationships, whereas others felt that teleworking blurred the boundary between work and family life and therefore made it more difficult to balance work and family demands.

Telework affects different aspects of work-family conflict. Selgrade and Davis (2005) studied a sample of teleworkers that included IT workers as well as workers from other professions from eleven organizations throughout the United States. They found that the effects of work interfering with family (WIF) were different than the effects of family interfering with work (FIW). Results showed that WIF, but not FIW, was negatively related to telework satisfaction and organization commitment and positively related to turnover intentions. Moreover, WIF increased with telework duration, whereas FIW increased with the number of children (Selgrade, 2004).

We report the following findings from a study of IT workers in eleven organizations. Major, Davis, Sanchez-Hucles, Germano, and Mann (2006) describe the research in more detail. We report here differences between IT teleworkers and nonteleworkers. All differences are statistically significant except where noted.

Forms of Telework

We found that 39.8% of IT workers report teleworking (less than one day per week to five days per week), mostly from home. Of those teleworkers who reported working at home, the majority of them do so less than one day per week (78.3%), whereas 21.7% report working from home one day per week or more. Of those teleworkers who reported working at telework centers or satellite offices, the majority of them do this less than one day per week (59.1%), whereas the remainder (40.9%) report teleworking one day per week or more. Finally, of those teleworkers who reported working on the road, 47.2% report doing this one day per week or more.

Table 1. Frequencies of demographic variables for IT teleworkers and nonteleworkers

Demographic Variable	Teleworkers: Percent of Total Teleworkers	Teleworkers: Male	Teleworkers: Female	Nonteleworkers: Percent of Total Nonteleworkers	Nonteleworkers: Male	Nonteleworkers: Female
Total sample[a]	39.8%	67.5%	32.5%	60.2%	55.9%	44.1%

[a] *Females comprise 39% of the sample; 36.3% of them telework. Males comprise 61% of the sample; 48.3% of them telework.*

Demographic Profile of Teleworkers

Gender

Females comprise 39% of the total sample; only about 1/3 (36.3%) of them telework (see Table 1). Males make up 61% of the total sample, nearly 1/2 (48.3%) of them telework. Consistent with national data (Davis & Polonko, 2001), male IT workers are more likely to telework than women.

Race

Whites were slightly more likely to telework, but there were no significant racial differences between teleworkers and nonteleworkers. The finding of racial balance in teleworking is consistent with national patterns (Davis & Polonko, 2001).

Relationship Status

We examined whether IT teleworkers tend to be single or in a committed relationship. We define "single" as those individuals who reported being single, divorced, or widowed and "committed" as those individuals who reported being married or living with their partner. Teleworkers and nonteleworkers were similar in their relationship status. These results mirror national data (Davis & Polonko, 2001).

Number of Children

Teleworkers and nonteleworkers were similar in the number of children they had. When examining only teleworkers, we found that the gender breakdown mirrored that of the overall sample; male teleworkers tended to have slightly more children (M = 1.29) than did female teleworkers (M = 1.02).

Highest Degree and Salary

Consistent with national patterns (Davis & Polonko, 2001), teleworkers had a higher educational level and a higher salary than nonteleworkers. IT workers in our sample were highly educated; most (71.7%) had at least a bachelor's degree. More than three-quarters of teleworkers (76.2%) had at least a bachelor's degree, while this was true for just over 2/3 of non-teleworkers (68.5%). This difference was not statistically significant. While males and females did not differ in terms of their highest earned degree, they did differ in terms of their salary; not surprisingly, males earned significantly more than females. When examining teleworkers only, men still earned higher salaries than women.

IT Position

Participants were asked to indicate their current IT position by selecting one of the following categories: conceptualizer, developer, modifier/extender, supporter/tender (see Key Terms). The breakdown was very different in terms of teleworkers vs. nonteleworkers. Proportionally more teleworkers were conceptualizers; proportionally more nonteleworkers worked in supporter/tender positions. These findings are not surprising because supporter/tender positions require IT workers to be in close proximity to the equipment and people they are responsible for supporting, whereas conceptualizer jobs do not. Supporter/tender positions may not allow the geographic and scheduling flexibility required of telework.

Elder Care

We were interested in whether or not teleworkers more than nonteleworkers chose telework because they were responsible for the care of an elder adult and needed the freedom to work from home. There were no significant differences in elder care between teleworkers and nonteleworkers.

Individual vs. Team Work

We asked participants whether they worked alone or as part of a team. We thought that the benefit of telework might be restricted to those who do not work with others. We found that teleworkers and nonteleworkers were similar in emphasis on individual vs. teamwork; the gender breakdown within this variable was similar as well. This finding lends support to the notion that even individuals who work in teams can telework.

Total Hours Worked

We examined the total number of hours worked per week by IT workers. Previous research suggests that one of the disadvantages of telework is that teleworkers tend to work more than nonteleworkers (Davis & Polonko, 2001; Mirchandani, 1998). The findings from the current sample support previous research; teleworkers in our sample worked significantly more hours per week (M = 48.55) than did nonteleworkers (M = 45.25). In addition, for the entire sample, males worked significantly more hours per week (M = 47.52) than did females (M = 45.42). However, when we examined the teleworker and non-teleworker samples independently, the gender results were different. In the teleworker sample, males worked significantly more hours per week (M = 49.37) than did females (M = 46.92). In the non-teleworker sample, there was no significant difference between males (M = 45.80) and females (M = 44.51) in the number of hours worked per week. These results are consistent with previous research that suggests that men and women use the extra time they save through teleworking in different ways. Males tend to use this time to do more job-related work, hence their longer working hours; whereas females may use this time to do more family-related work such as household chores (Steward, 2000).

CONCLUSION AND FUTURE TRENDS

Telework is a growing response to the need of organizations to reduce costs, enhance flexibility, and attract and retain workers with valuable skills. It is one way to create virtual teams and virtual organizations. Inexpensive information and telecommunications technologies and increasing global competition will accelerate this trend for IT organizations (Davis, 1995). IT workers, because they engage in knowledge work and are skillful at using information technology, are particularly well suited for telework.

Researchers are just discovering the consequences of telework and how to manage it effectively. Much telework research has been limited by reliance upon small convenience samples, poor measurement, inadequate statistical analysis of results, and inadequate grounding in organization theory (Bailey & Kurland, 2002). Management practice has lagged as well, with little understanding of how to alter organization structures and processes to make telework practice successful (International Telework Association and Council, 2000). There is a great need for well-designed research studies of telework in IT.

Women in many professions throughout the United States participate in telework. Women in our sample of IT workers participate extensively in telework as well, but when compared to men, they participate at a lower rate in comparison to national practice (IT teleworkers in our sample: 67% male, 33% female; national sample in U.S.: 54% male, 46% female; Davis & Polonko, 2001). This difference may be unique to the organizations in our sample. This difference also may be due to institutional barriers such as resistance to remote work among IT managers and work design barriers such as the need to tend to centrally located equipment around the clock. Future research should continue to explore gender differences in telework among IT workers and identify possible barriers and enablers. These results may then be used to help IT organizations and IT workers increase flexibility by distributing IT work away from the traditional office. This flexibility will enhance efforts to balance work and family needs as well as organizational competitiveness.

KEY TERMS

Conceptualizer: Someone who conceives of and sketches out the basic nature of a computer system. Job titles include: product designer, research engineer, systems analyst, computer science researcher, requirements analyst, and system architect.

Developer: Someone who works on specifying, designing, constructing and testing information technology. Job titles include: system designer, programmer, software engineer, tester, computer engineer, microprocessor designer, and chip designer.

Distributed Work: Work that is distributed across geography and time. Distributed work may take several forms, (e.g., telework, telemedicine, virtual teams, and virtual organizations).

Knowledge Work: Work that consists of the creation and manipulation of ideas and symbols. Knowledge work is common in IT and is ideally suited for distributed work because it is easily digitized and may be done anywhere and anytime.

Modifier/Extender: Someone who modifies or adds on to already created information technology. Job titles include: maintenance programmer, programmer, software engineer, computer engineer, and database administrator.

Supporter/Tender: Someone who delivers, installs, operates, maintains or repairs information technology. Job titles include: system consultant, customer support specialist, help desk specialist, network installer, and network administrator

Telework: A type of distributed work in which employees work at locations other than the traditional workplace. Major types of telework include: (1) home-based telework–working from home; (2) satellite offices—employees from the same company work at the same location closer to their home, often in suburbs or exurbs; (3) telework centers–similar to a satellite office except that the telework center hosts employees from different organizations; (4) mobile work—working at multiple locations away from the office (e.g., at client work sites, while traveling).

Virtual Organization: A form of organization design in which organization structures and functions are distributed across time and geography.

Virtual Team: A form of work design in which members of the same work group are distributed across time and geography; usually compared to traditional collocated teams, where all team members are located at the same site.

Gender and the Australian IT Industry

Lorraine Staehr
La Trobe University, Australia

Graeme Byrne
La Trobe University, Australia

Elisha Bell
Department of Employment and Workplace Relations, Australia

INTRODUCTION

From its very beginnings in the post second world war years the information technology (IT) industry in Australia has exhibited gender stereotyping with the relegation of women to lower paid and lower status jobs. Unfortunately the words of Game and Pringle (1983) are as true today as when they were written more than twenty years ago:

The sexual division of labor is not a remnant from the feudal past that is gradually being eliminated, but is a fundamental structural feature of capitalist society. (p. 81)

The first IT projects were funded by the military when IT had a mathematics or science image. Neither of these characteristics was likely to make an IT occupation attractive to women. However some women were employed by small IT consultancies wanting to save money because in the 1950s in Australia, women were only paid around 75% of a male wage (Game & Pringle, 1983, p. 84). Opportunities arose for women to move into the IT industry in the late 1960s due to a skills shortage. However this had little long term impact as today women are still under-represented in the industry.

BACKGROUND

The trends over the three most recent census years (see Table 1) show little overall change in women's participation rate in the Australian IT industry. The drop of 2.6% in women's participation rate from 1996 to 2001 was at a time when the number of employees in the IT industry increased by 52%. The 2001 census data shows that few women are in management roles in IT in Australia. Also, as in most other occupations there are income disparities between men and women with women concentrated in lower income occupations. For a full discussion and analysis of the Australian IT industry data for the census years 1996 and 2001 see Byrne and Staehr (in press).

During the same period, the number of women with IT qualifications decreased by 6.3% despite the total number of persons with IT qualifications having increased by almost 70% between 1996 and 2001 (shown in Table 2).

The figures in Table 1 and Table 2 show that there are far fewer women working in the IT industry than there are women with post secondary school qualifications. Note that one reason for more woman with IT qualifications than women in IT occupations is that the women with occupations that come under the heading of education (e.g., secondary, TAFE, and university teachers) are not included in the figures in Table 1.

The number of women working in the IT industry is affected not only by the number of women gaining IT qualifications from universities, but also from Technical and Further Education (TAFE) Colleges

Table 1. The participation rates of women (WPR) in the Australian IT industry (ABS, 2002a)

Census Year	Women	Persons	WPR
1991	17370	72889	23.8%
1996	32733	126375	25.9%
2001	45408	192132	23.6%

Table 2. Post-secondary school qualifications in IT (ABS, 2002b)

Census Year	Women	Persons	%Women
1991	18986	51633	36.8%
1996	33114	90704	36.5%
2001	46707	153183	30.5%

and private education providers (e.g., Computer Power). In addition, there will be women both already in, and entering the IT industry without formal qualifications in IT. It is only since 1997 that membership of the Australian Computer Society (ACS) at the highest level normally requires formal IT qualifications. Accenture, a well known IT consulting company, advertises for graduates from Commerce, Law, Arts, Engineering, and Science as well as IT. Therefore, there are multiple pathways for women to enter the IT industry in Australia.

However, there is anecdotal evidence to show that women with IT qualifications are choosing to work in other occupations (Fisher, 2003). The figures in Table 2 are particularly disturbing since during this period the Australian Government and the universities made considerable effort to increase the participation and retention rates of women in IT education (Newmarch, Taylor-Steele, & Crupston, 2000). The actual numbers of women obtaining IT qualifications has increased from 1991 to 2001 but has not kept pace in relative terms with the overall employment trends in the Australian IT industry.

Thus, no matter how you look at it, the Australian IT industry is failing to attract/retain women and the situation is getting worse. Possible causes that have been identified are misconceptions about the nature of IT work, unfriendly male dominated workplaces, and the fact that long hours required by some IT work making it difficult to balance work and home responsibilities (Johnson & Miller, 2002; von Hellens & Nielsen, 2001). However, a close examination of the job roles available reveals that IT offers opportunities to work with people in a team environment, challenge and variety in work tasks, good pay and opportunities to travel, all attributes that women are likely to find attractive in a career.

One avenue for investigation of the under representation of women in IT is through an examination and comparison of the effect of individual company policies and government legislation on what women actually experience in the IT workplace. The national culture of an organization and public policy usually impact on company policies (Trauth, 2002; Trauth, Nielsen & von Hellens, 2000; von Hellens & Nielsen; 2001). For example, the culture of an American company located in Australia would be different to the culture of an Australian company within Australia. An example is an IT professional who was happier working for a Scandinavian company in Australia rather than an Australian company as she believed there was a strong workplace culture of equality coming from the Scandinavian head office (Trauth, Nielsen, & von Hellens, 2000; von Hellens & Nielsen, 2001). This suggests that company policies based on a culture of equality may positively affect an individual's workplace experiences. In contrast though, Woodfield's (2000) study of a software company in the United Kingdom found that although official company policies valued individuals with the right mix of skills regardless of sex, this did not necessarily match what happened in practice. And some people believe women are in the IT workplace to meet with government affirmative action legislation and not for their actual skills and abilities (Trauth, 2002).

It is claimed by Kirner and Raynor (1999, p. 170) that anti-discrimination laws are better accepted in Australia than in any other western country. Australia has had a Federal Equal Opportunity for Women in the Workplace Agency since 1986. This agency administers the Equal Opportunity for Women in the Workplace Act 1999. The Act requires companies with 100 or more employees to establish a workplace program to remove the barriers to women entering and advancing in the workplace and to report regularly to government. The sanctions for non-compliance are that the company will be named in parliament and the company will be ineligible to tender for government contracts and industry assistance. Companies with particularly good policies are eligible to win awards and have their names publicized in the media, providing incentives for companies to have woman-friendly workplace policies.

There are also a number of Australian Commonwealth, State and Territory government laws that make sexual harassment and discrimination unlawful (e.g., Sex Discrimination Act 1984 (Cth), Equal Opportunity Act 1995 (Vic). In addition, even Federal industrial laws seek to achieve anti-discrimina-

*Table 3. Background of participants (*participant names are pseudonyms)*

*Participant	Age at Graduation	Number of Years in the IT industry	Current Age of Children	Job Title at Time of Interview

Anne	40	7	18 years old and 20 years old	IT Officer
Sharon	29	6	3 years old and 13 months old	Business Analyst
Linda	22	9		Chief Operations Officer
Rachael	21	13	4 years old and pregnant at time of interview	Systems Administrator
Jane	22	4		Applications Support Programmer
Sara	22	5		Senior Internal Auditor
Vanessa	21	11		Senior Web Analyst/ Programmer
Kirsty	21	7		Area Specialist/Team Manager

tory objectives. For example, maternity leave provisions are included in the Workplace Relations Act 1996 (Cth).

SO, HOW DO WOMEN EXPERIENCE THE AUSTRALIAN IT WORKPLACE?

In a small exploratory qualitative study Bell and Staehr (2004a, 2004b) investigated how women experience the Australian IT workplace. The aims were threefold: to see if the same issues which women had identified in the past as barriers to working in IT were still a problem, to discover any new issues and to compare the women's experiences with company workplace policies and government legislation. The literature was examined and provided eight broad themes from which an interview protocol was developed. Interviews were conducted between November 2002 and April 2003. Company policies were either collected from participants or obtained from company Web pages.

Table 3 outlines the background of the nine participants in the study. Mary declined to be interviewed face to face, however she answered the interview questions via e-mail.

Table 4 shows the major themes that emerged from the analysis of the interviews and indicates where if at all, these themes were found in the existing literature. More detail on the two themes that have not previously been reported in the literature is given below.

Two participants who had young children felt that management had not supported them as mothers. In her current job, Rachael's management was unsupportive by only offering her twelve months of continuous maternity leave, although she knew she was entitled to a more flexible arrangement. Rachael had to leave a previous employer because her needs after her first maternity leave were not met. To accommodate her desire to both work and have a family, she has had to move to a lower paid job. When Sharon first starting working part-time she was removed from a team, as her manager did not want any part-time members. Sharon would like to reduce her time fraction further but her manager is unsupportive of her request.

Two of the participants mentioned difficulties when working with men of different cultural backgrounds. Sharon recalled when a colleague refused to converse with her on the telephone. According to Sharon, the attitudes of men who are not used to working with female colleagues in IT are poor. As Australian firms are outsourcing more and more projects overseas this sort of problem is likely to occur more frequently. Sara also noticed that men

Table 4. Major themes

Theme	Participant	Other Studies

Management does not support mothers	Sharon, Rachael	
Difficulty of achieving a work-life balance	Vanessa, Kirsty, Sharon, Sara	Pringle et al. (2000), von Hellens & Nielsen (2001), Johnson & Miller (2002), Webb & Young (2005).
Lack of challenging work	Anne, Linda, Kirsty, Rachael, Sara	Hemenway (1995)
Difficulties of working with men from a different culture	Sharon, Sara	
"Boys club" culture	Rachael, Sara	Bruce & Adam (1990), Gill & Grint (1995); Hemenway (1995), Teague (1998), McCracken (2000), Nielsen et al. (2000), Pringle et al. (2000), Suriya & Panteli (2000), Trauth et al. (2000), von Hellens et al. (2001), von Hellens & Nielsen (2001), Webb & Young (2005).

from different cultures treat women inappropriately. According to Sara, being a woman and asking questions or addressing management is unacceptable behaviour in certain cultures.

During the interviews, five of the participants reported that they had given thought to leaving their current employer due to the work not being challenging enough. It was reported by Panteli, Stack, Atkinson, and Ramsay, (1999) that lack of challenge in a current IT position is the most often quoted reason for both men and women to leave an employer. However, it is given as a reason more often by women than men.

Seven of the participants were able to share with the researcher their current workplace policies. However, the experiences of five participants did not match that of their workplace policies and/or government legislation and are summarised in Table 5.

Workplace policies and government legislation do not seem to guarantee fair treatment for women in the Australian IT workplace. Interestingly, the company where Rachael currently works has won an award for its workplace policies.

All of these women worked for companies that needed to conform to government requirements for workplace policies for women. At the time of writing the requirement is only to have policies in place but there is no compulsion for companies to ensure that the policies are actually achieving benefits for women. Organisations need to make sure individual managers are informed about the policies, and that measures are put in place to ensure adherence to them.

FUTURE TRENDS

The failure to increase the participation rate of women in the Australian IT industry over the last ten years is a disturbing trend. Unfortunately there seems to be a prevailing attitude that this battle has already been fought and won. Our small study showed that some women today are still finding some aspects of the IT workplace an unfriendly place for women. Problems where women were working with men from other cultures are not surprising due to the recent increase in off-shoring of IT work and an increasingly more multicultural society in Australia. Management need to be aware of the problems that women may encounter in these situations.

Government legislation and workplace policies designed to improve workplace conditions for women do not seem to be having an effect. Unfortunately, most Australian employers see equal opportunity for women as a risk management issue that reduces legal exposure. Equal opportunity needs to be seen as a strategic business initiative that will increase profits (Why EO Makes Good Business Sense, 2004). Until employers get the message that providing a woman-friendly workplace can attract high

G

Table 5. Participant experiences matched with relevant legislation and/or company policy

Participant	Experience	Relevant Government Legislation or Workplace Policy	Country Of Origin Of Current Employer
Mary	Sexual harassment	Sex Discrimination Act 1984 (Cth).	Unknown
Anne	Sexual harassment	Sex Discrimination Act 1984 (Cth).	Australia
	Not being given challenging tasks.	Equity and Diversity Plan - "…everyone should be given an equal chance to make the most of their own talents and use their abilities".	
Sharon	Not able to reduce her time fraction.	Part-time employment policy.	USA
Rachael	Pressured to apply for a continuous twelve month maternity leave period rather than take two six months periods.	Workplace Relations Act 1996 (Cth) Enterprise Bargaining Agreement – "An employee shall be entitled to extend the period of maternity leave".	Australia
Jane	Not being selected to work on development projects. Therefore overlooked for career advancement.	Affirmative Action (Equal Employment Opportunity For Women) Act 1986 (Cth) Equal Opportunity Act 1995 (Vic) Workplace Diversity Policy – "Affirmative action is about identifying and addressing the barriers that prevent women from entering or advancing in the workplace."	Australia
Sara	Not able to achieve a healthy work-life balance	Company Internet – "a healthy work/life balance and employee diversity are valued".	Australia

quality employees and increase profits there is not likely to be an increase in women's participation rate in the Australian IT industry.

CONCLUSION

Some of the issues raised by the women in our study of the IT work place confirm the findings of previous research. However the difficulty of working with men from a different culture, lack of support for mothers and the lack of challenging work affecting job satisfaction have not previously been reported in the Australian context.

More work is required to confirm the findings of this research. Future work will involve the study of both male and female IT professionals in several organizations with the aim of comparing their experiences with workplace policies and government legislation. Another planned research direction is to identify the best ways for organizations to successfully implement women-friendly policies.

KEY TERMS

Affirmative Action: In the context of employment it involves pro-active steps taken by an employer to ensure the provision of equal employment opportunity.

Equal Opportunity: Equal opportunity (EO) in a workplace context means that all employees have equal access to the opportunities that are available at work. This means all employees are treated with fairness and respect in that they are not subject to discrimination or harassment in the workplace". (Source: Retrieved February 6, 2006, from http://www.eowa.gov.au/About_Equal_Opportunity.asp)

Gender Stereotyping: In the context of occupations, some jobs in some societies are considered only suitable for males or only suitable for females.

Post Secondary School Qualifications: Are grouped by the Australian Bureau of Statistics Classification of Qualifications into:

- **Bachelor Degree and above:** Bachelor degree (including honours), graduate or postgraduate diploma, master's degree or doctorate
- **Undergraduate Diploma:** Courses lasting three years full-time (or equivalent) for professional or associate professional occupations
- **Associate Diploma:** One to two years full-time (or equivalent) for advanced trades, technical or associate professional occupations
- **Skilled Vocational Qualification:** Two to four years study for work in a high skilled trade or craft
- **Basic Vocational Qualification:** One semester to one year study for work at the operative level in various fields

Sex Discrimination: "Occurs when a person is treated less fairly than another person because of their sex or marital status or because they are pregnant. This is direct discrimination. Indirect discrimination can also occur when a requirement that is the same for everyone has an unfair effect on some people because of their sex, marital status, pregnancy, or potential pregnancy."(Source: Retrieved February 6, 2006, from http://www.acas.org.uk/faqs/discrimination.html#5)

Sexual Harassment: "Sexual harassment is any unwanted or uninvited sexual behavior which is offensive, embarrassing, intimidating or humiliating. It has nothing to do with mutual attraction or friendship." (Source: Retrieved February 6, 2006, from http://www.apesma.asn.au/adviceonline/entitlements/discrimination. htm#SEX%20 DISCRIMINATION)

Women's Participation Rate: The percentage of women as a proportion of the total number of persons employed in IT occupations in Australia.

Gender and the Culture of Computing in Applied IT Education

INTRODUCTION

The "shrinking pipeline" of women who ascend through the ranks in computer science education programs and careers is by now a familiar problem. Women drop out at rates faster than men at all levels of educational and professional advancement, resulting in a gender gap especially pronounced at the highest levels of the computing workforce, and that has not narrowed appreciably at any level in more than 20 years (Camp, 1997; ITAA, 2005; Vegso, 2005). Efforts to move more women into the pipeline at lower levels have met with limited success (cf. the Carnegie Mellon experience as reported by Margolis & Fisher, 2002); girls and women still express less interest than boys and men in studying computer science and pursuing information technology (IT) careers (Bentson, 2000; Vegso, 2005).

A reason often cited in the literature is the masculine culture of many computer science programs and IT workplaces, which is perceived by many women as alien and unwelcoming (Bentson, 2000; Spertus, 1991; Turkle, 1988). Even when institutions make efforts to treat women and men equally or accord women special consideration in admissions and hiring decisions, attitudes discouraging women from entering computing persist, both within the institutions and in society at large. Sometimes these attitudes are expressed overtly: Underground "hacker" culture is notoriously antagonistic to women (Gilboa, 1996), and even mainstream computer aficionados respond with resistance and sexist jokes to proposals to recruit more girls and women to study computer science (Slashdot.org, 2005). Moreover, there is a widespread perception that computer experts are socially-isolated "geeks" or "nerds" obsessed with technology, a mode of being that women, who tend to be more socially oriented, find unappealing (Margolis & Fisher, 2002; Turkle, 1988).

Fortunately, the situation for computer science does not tell the whole story. In the latter part of the 20th century, the expansion of computing and the Internet fueled the rise of applied IT fields in which technical skills, rather than being developed for their own sake, are increasingly put to use in the service of human needs. Applied fields, such as information science, information systems and instructional technology, have gained strength, and a new interdisciplinary field, informatics, has emerged. At the same time, interest in computer science itself is declining, especially among women (ITAA, 2005; Vegso, 2005). In this article, we explore the possibility that applied IT fields may provide more women-friendly cultures while still focused on technology. The larger question underlying this exploration is: Does applied IT education have the potential to bridge the "gender computing gap"?

BACKGROUND

Previous research has focused primarily on problems faced by women in computer science, especially in undergraduate-level education (Camp, 1997; Cohoon, 2001; Spertus, 1991). Many influences have been cited as contributing to the educational gender gap in computer science, including aspects of institutional culture, such as lack of role models (Pearl, Pollack, Riskin, Thomas, Wolf, & Wu, 1990), mentoring and advising (Whitely, Dougherty, & Dreher, 1991), informal networking (Smith-Lovin & McPherson, 1993) and a sense of belonging and identity (Ely, 1995); work-family conflict (Netemeyer, Boles, & McMurrian, 1996); and teaching styles (Cohoon, 2001; Turkle, 1988).

One of the most often-cited factors that discourage girls and women from studying computer science is the culture of computing itself: Computing is historically and conventionally associated with masculinity, an association that attracts boys to computers who then become role models for other boys, creating environments in which girls feel marginalized (Hacker, 1990; Turkle, 1988). Citing Margolis and Fisher (2002), Read (2002) argues that "women are further alienated by a stifling 'geek culture' that celebrates obsessive computing at the expense of broad interests." Hackers are perceived as keeping exceptionally long hours and late nights, and manifesting "highly focused, almost obsessive behavior" (Frenkel, 1990, p. 38). For many women, this work ethic conflicts with their desire to start a family or, if they are older, their actual family responsibilities. Meanwhile, hackers, who are predominantly male, are seen as being "bright and creative," while women remain on the periphery. Rasmussen and Hapnes (1991) suggest that this type of culture is important in producing and reproducing male domination in higher education in computer-related fields and that it influences the integration of women and their position within the field of computing.

The abstractness of much computer science instruction exacerbates the gender-biased culture, in that girls are more likely to be interested in real-world problem solving in contexts involving human users than in machines and programming languages (Clarke, 1992). A related deterrent for women is that most introductory computer science courses focus on programming skills rather than concepts of computer science. Girls and women like IT, the findings suggest, but want to do something with it to improve the world; they are not satisfied with mastering computing skills for their own sake.

Applied fields such as information science, information systems and instructional technology have an a priori advantage over computer science when it comes to attracting future female professionals. They are grounded in the disciplines of real-world problems; for example, business, education and information management. Indeed, while women are significantly underrepresented in the IT workforce overall (ITAA, 2005), especially in computer science (Bryant & Vardi, 2002), applied careers, such as education and library and information science, attract higher proportions of women (e.g., Maata, 2003). However, research on the status of women in these professions shows mixed outcomes. On the one hand, women in applied disciplines are more likely to achieve professional parity or near parity with men (Quint, 1999; Wolverton, 1999). On the other hand, even in female-predominant applied professions such as education and library science, most high-ranking administrators are men (Growe & Montgomery, 2000; McDermott, 1998). Moreover, men tend to be disproportionately represented in IT work in these fields, which also tends to be more highly paid and more prestigious (e.g., Harris, 2000 for library and information science).

Little has been written about what leads women (or men) to choose applied IT careers, or what kinds of disciplinary cultures they encounter when they decide to study an applied IT domain. That is, there is no body of literature directly comparable to that available for computer science on which to base predictions about the long-term effects of the growth of applied IT fields on the gender computing gap. To address this research gap, we initiated the Information Technology Workforce (ITWF) project.

INFORMATION TECHNOLOGY WORKFORCE PROJECT

The ITWF project, funded by the National Science Foundation,[1] has been collecting and analyzing data on the experiences, attitudes and outcomes of women and men in IT programs at five large public universities in the United States (U.S.)[2] since September 2003. The focus is on students at all levels majoring in applied IT disciplines, specifically: information systems (IS), instructional systems technology (IST), informatics (I) and library and information science/

studies (LIS). We expected to find differences among these fields and between applied fields and computer science (CS); more generally, we expected that more female-oriented ("women-friendly") disciplinary cultures would produce more successful outcomes (Jones, 1990), where success is defined both in terms of the quantity of women who enter IT-related educational programs and the quality of their educational experiences (Ahuja, Herring, Ogan, & Robinson, 2004).

Data collection for the project as a whole is via Web-based surveys, telephone interviews and face-to-face interviews with students, faculty and staff in the IT programs. In this article, we focus on findings from an initial Web survey of all IT student majors in the five universities (from the four applied IT fields plus computer science) that took place in spring 2004. The survey asked 100 questions about students' experience, behaviors and attitudes regarding computers; their parents' occupations and attitudes toward gender roles; student demographic information; and information about mentoring, stress and burnout in their academic environment.[3]

SELECTED FINDINGS

The results of the survey were revealing of the attitudes and experiences that influence students in their selection of an IT career. Three distinct patterns emerged, showing variation according to gender, IT discipline and the interaction between gender and discipline.

Gender-Based Variation

For some survey questions, men and women tended to answer differently, regardless of their program of IT study.[4] For example, one question asked students to assess the relative importance they place on their career and their personal life. While most people answered that the two are equally important, females were more likely to choose the balanced response, while males were more likely to say that their careers are more important. This is consistent with previous observations that men in IT are more focused on their work, while women seek a more balanced lifestyle (Frenkel, 1990; Margolis & Fisher, 2002).

Another series of questions asked about work/life balance as a potential cause of stress. Most students answered "occasionally" or "seldom" to questions about whether schoolwork interferes with personal life and vice versa. However, women were more likely to say that school strain affects their personal life all the time, and men were more likely to respond that it never does. This could be a reflection of female students having greater domestic responsibilities (Netemeyer et al., 1996); more of the female than male survey respondents said they were married and/or had children at home.

Unsurprisingly, most of the IT students reported that they feel very comfortable using computers. However, here, too, a gender pattern is evident. Males in all majors were more likely to answer that they are very comfortable, whereas females gave most of the "somewhat comfortable" or "not at all comfortable" responses; this includes women in CS. Women also reported learning to use computers later than men, and playing fewer computer games when they were children.[5]

These results support previous findings on gender differences in early computer experience and in computer self-efficacy (Durndell & Haag, 2002; Fromme, 2003), suggesting that some manifestations of the gender computing gap persist in applied IT disciplines.

Discipline-Based Variation

Differences are also evident within the IT disciplines, independent of respondent gender. A common tendency was for responses for LIS and IST to pattern together, in contrast to responses for CS and IS, with informatics falling in between. For example, when asked to weigh the relative importance of their career vs. their personal life, students in IS and CS were more likely to indicate that career was more important, and students in LIS and IST were more likely to say that their personal lives mattered more. Perhaps not coincidentally, students in IST and LIS also expressed greater satisfaction with their majors than did the IS and CS students.

Conversely, when asked what attracted them to their IT career choice, students in IS singled out earning a good living, and students in CS cited the challenge inherent in the subject matter. These considerations were rated less important by students in IST and LIS, for whom helping others was the highest consideration.

Disciplinary differences were also found with regard to students' backgrounds and childhood experiences. CS and IS students were more likely to have had a father and/or mother who worked in an IT-related profession. CS, IS and informatics students clustered together in terms of where and when they first started using computers (at home, before or during their elementary school years) and the amount they played computer games as children ("very frequently" or "frequently"). Of those who answered that they did not learn to use a computer until high school or college, and played games "rarely" or "never," most were from IST and LIS.

When asked what kind of job they expected to find after graduation, a majority of the respondents, with the exception of IST students, answered "scientific or technical." In addition, CS students preferentially indicated "university teaching and research," and IS students indicated "administrative/managerial," "consulting" and "sales." IST students responded "consulting" and "K-12 teaching," and LIS students indicated "administrative/managerial," "clerical" and "other." It is hardly surprising that different disciplines target different careers; however, the students' career expectations in CS and IS (e.g., industry researcher, professor) tend to be higher status and better paid than those in IST and LIS (e.g., K-12 teaching, clerical). Computer science and business are traditionally "masculine" fields, whereas education and library science are traditionally considered "feminine" professions.

Gender and Discipline Variation

In the third pattern of survey results, gender and IT discipline interact. Specifically, males in traditionally masculine disciplines tend to pattern together with females in traditionally feminine disciplines, and females in traditionally masculine disciplines pattern together with males in traditionally feminine disciplines. These results suggest a natural mapping between the gender of the student and the traditional gender associations of the discipline.

For example, the survey asked students to indicate their degree of satisfaction with their major. While most answered "very satisfied," CS men and IST/LIS women were overrepresented on that response. The inverse pattern was found for the less-enthusiastic response "somewhat satisfied": CS women and IST/LIS men were overrepresented. In particular, women in IST and LIS selected "very satisfied" much more often than did women in CS, consistent with our expectations that IST and LIS are more "women-friendly" cultures (Jones, 1990).

Or consider another set of results, in response to the question, "How similar are your values to those of your field?" IS males and IST/LIS females were most likely to answer "very similar," and informatics females and IST/LIS males were most likely to answer "not at all similar." If we consider informatics to be part of the CS/IS cluster, this instantiates the same pattern.

Students' confidence about finding a job after graduation displays a similar cross-distribution. Males in CS and females in IST/LIS were most likely to answer that it will be "very easy" to find a job; LIS males and male students in CS and informatics were most likely to answer "very hard," and women in CS and informatics were overrepresented in the "don't know" category. There seem to be two types of male CS student; those who are very confident and those who are more pessimistic about their job prospects. Apart from this, these results also fit the tendency for confidence and satisfaction to accompany a mapping of student gender onto IT discipline.

DISCUSSION

The results of a Web-based survey of students in different IT programs in five U.S. universities reveal gender differences among students, differences among IT disciplines and a mapping of gender onto disciplinary cultures, all of which potentially affect students' choice of and satisfaction with an IT career. Rather than clustering together in contrast to CS, the responses of students in applied IT programs tended to fall out along gender and disciplinary lines, with CS and IS clustering at one end, and LIS and IST at the other; informatics, the new discipline, mostly fell in between.

Somewhat discouragingly, the women in the applied IT programs, like the women in computer science, report having less early computer experience and less confidence in their computing abilities than their male peers (Ogan, Ahuja, Robinson, & Herring, in press). At the same time, the female students' reported preference for a balanced lifestyle may help to explain why more women choose applied IT majors than CS. The most popular IT majors among women in our study are those that are traditionally feminine, in which there are more women peers and role models, and which value using technology to help people. Fewer women choose IT majors where the focus is on technology for its own sake (in the case of CS) or making money (in the case of IS),[6] although the women who choose those majors appear to do so for those reasons, similar to men. Most intriguingly, both genders report greater satisfaction with and optimism about their career choices in IT disciplines that mirror the gendered cultures found in society at large.

FUTURE TRENDS

These findings are simultaneously encouraging and problematic. On the one hand, they suggest that the rise of applied IT fields does indeed open the door to more women studying and working in IT. Specifically, the findings indicate that IT programs located in traditionally "women-friendly" contexts may be more accessible and appealing to women, and by extension, that other IT contexts might evolve to become more women-friendly as well. Informatics is an example of a discipline whose culture has not yet become fixed; in this study, it tended to pattern weakly with CS and IS, but that tendency could shift.

At the same time, the survey findings are problematic in that they re-inscribe cultural stereotypes about gender roles and interests in the IT domain. Moreover, a positive interpretation of the results assumes an equivalence between the various IT fields that is more illusory than real. "Feminized" professions such as instructional design and librarianship still have less status and are lower paid, even when they incorporate IT (Lorenzen, 2002). Moreover, the computing technology involved is typically less rigorous than in computer science (e.g., it may not require practitioners to know how to program a computer). Does women's greater satisfaction with applied IT programs help to bridge the gender IT gap, or does it reproduce a larger societal status quo, of women as less technology- and career-oriented?

Ideally, IT study should be equally accessible and rewarding for women interested in hard-core computing and men interested in human applications as it is for men interested in, for example, grid structures, or women interested in information management or educational applications. Again, informatics may help to bridge the gap if a culture can be forged in which technical rigor is balanced with a focus on computing applications that benefit people.

CONCLUSION

This study has raised a previously unasked question about the potential of applied IT fields to close the gender computing gap. The question remains, for the most part, unanswered; further research needs to be done, for example, to compare the IT content of applied IT programs, and to take national culture (in addition to disciplinary culture) into account in assessing the appeal and outcomes of different approaches to IT. In the meantime, enrollments in CS are declining in U.S. universities (Vegso, 2005) and the IT workforce is aging (ITAA, 2005), but society's need for IT expertise remains high. In the future, it is likely that career seekers of both genders will turn increasingly to applied IT and to the new interdisciplinary paradigms emerging from combinations of computing, information studies and other fields (Berghel & Sallach, 2004). It is important to understand the social dynamics and implications of these trends, in the hope that we may be able to shape them into gender-equitable configurations.

KEY TERMS

Applied IT: Programs of study and careers in which information technology is applied in contexts of use; for example, business, education, libraries.

Computer Science (CS): In this article, a university program teaching computer science.

Gender Computing Gap: The relative absence of women in computing-related programs of study and careers, especially computer science.

Informatics (I): A new interdisciplinary area of study in the U.S., with roots in computing applications to medicine, and university programs that teach it.

Information Systems (IS): In this article, a university program teaching information systems; usually associated with Management in Business Schools.

Instructional Technology (IT): In this article, a university program teaching instructional technology; typically found in Schools of Education.

Library and Information Science/Studies (LIS): In this article, an academic program teaching library science, information science and/or other information management skills.

ENDNOTES

1. National Science Foundation IT Workforce Grant #0305859, "Toward Gender Equitable Outcomes in Higher Education: Beyond Computer Science."
2. Universities were selected that offered computer science plus a minimum of two applied IT programs.

G

[3] 1,768 students responded to the survey, of whom 1,516 indicated their gender.

[4] A "finding" in this article indicates a result for which a gender or discipline had values well above the mean for the specified discipline, based on descriptive statistics. Statistical significance was not measured and no claims of significant differences are made.

[5] See Ogan et al. (in press) for more detailed discussion of gender differences in the survey responses.

[6] Women are seriously underrepresented in both business information systems and computer science programs in our sample.

Gender and the Household Internet

Tracy L. M. Kennedy
University of Toronto, Canada

INTRODUCTION

Internet research has reached a point where a detailed analysis of household Internet use is necessary. Given that the household is a contested terrain for feminist theorists (Hochschild, 1989; Luxton, 1980), it is often a site of struggle between household members and a place where unequal divisions of domestic labour situate women as bearing the load of housework and caregiving (Cockburn & Furst-Dilic, 1997). How should researchers examine Internet use in the household?

There are two particular areas that need to be considered in order to contextualize household Internet use. The first is household roles: the interactions and relationships shaped by societal expectations and social roles (gender, class, and race). The second is the domestic division of labour: Who is responsible for domestic tasks and how does this influence household Internet use?

BACKGROUND

Previous research has begun to address notions of computers or the Internet in the home (Bakardjieva & Smith, 2001; Cumming & Kraut, 2001; Dryburgh, 2001; Habib & Cornford, 2001; Haythornwaite & Kazmer, 2002). However, they often do not examine everyday lived household experiences and their implications on the relationships between men and women, social roles, the division of labour, social interaction, and relationships in the household. Often, researchers do not connect these contexts to broader social relations such as race, class, and gender, and the relations of power inherent within the household.

The introduction of computers in the home in the 1980s (Frohlich & Kraut, 2002; Lally, 2002) notes the changing nature of computer use in the household context. In the 1980s, the few home computers that existed were used for word processing, telework, bringing work home, and children's games (Venkatesh, 1996). However, in the 1990s, it is evident that the nature of computer use changed and adapted to the household as it became domesticated; education, family communication, family recreation and travel, shopping, and domestic finances were common computer uses (Venkatesh).

Literature concerning the Internet in the home is often framed around how it has become domesticated, though this term seems to mean different things to different researchers and through different processes. What does it really mean? Domesticating something (an animal or person) denotes discipline, taming or civilizing, or making something fit for life in the home or able to participate in society (Habib & Cornford, 2001). Domestication can be conceptualized as shaping the use of technology in order to fit the household so that the technology eventually becomes embedded and almost invisible (Rommes, 2002). It is the way technology influences the user, and the user influences technology (Rommes). Information and communication technologies are often domesticated to serve people's own values and interests (Dutton, 1999). This indicates that the domestication of the Internet can vary from household to household, and the household is a continual site of cultural struggle over the meaning of the technology and what it should be used for (Murdock, Hartmann, & Gray, 1995). There is a need to better understand the process of domestication, which situates technology in diverse ways within the household (Silverstone, 1993).

MAIN THRUST OF THE ARTICLE

Household Roles

What must first be understood about household Internet use are the roles or the expectations that people have of one another in the household. Roles within the home are gendered and reflect race and class, and are often reinforced and strengthened through social interaction between people (West & Zimmerman, 1987). For example, there are existing social arrangements, cultural conditions, and practices that surround household technologies (Ribak, 2001), and the Internet in the household must be examined with this in mind. Examining how the household Internet is becoming domesticated should also address how a technology shapes and becomes a part of one's gender identity, and how women and men often relate to stereotypical images of gender identity (such as men being technologically competent; Rommes, 2002).

Women and men use the Internet differently and in different amounts because of social expectations guided by gender roles. Women utilize the Internet in ways that reflect their everyday gendered household roles (Shade, 2004); they are the communicators and networkers, and spend considerable time e-mailing family and friends more so than men (Kennedy, Wellman, & Klement, 2003). In contrast, men's use of the Internet is often less social as they spend more time searching for information and pursuing more isolated recreational activities.

Relations of power are important both in instances between parents, and parents and children, but also between those who have better Internet skills and those who do not. For example, it is often stated that women are less comfortable with technology than men (Ribak, 2001; Singh, 2001; Wajcman, 1991), thus they leave technological "fix-its" to others or use the technology less. As well, children's knowledge of the Internet often surpasses their parents'. In cases in which a household has only one computer, relations of power, based on skill or comfort, have an impact on the amount of time household members might spend on the Internet and who feels they are entitled to use it more. While there might be a power relationship between parents regulating children's use, the power is reversed when children are able to maintain and modify the household computer (Frohlich & Kraut, 2002).

As well, competition and struggle (Ribak, 2001) over the household Internet needs to be considered. Hierarchies of access and time available for household members will ultimately affect its use. Issues such as who can get on the Internet, at what time, and for how long are just as significant as what they do once they are online (Frohlich & Kraut, 2002). The question becomes what type of use by various household members is most important. Is this contingent on household roles? Internet use based on work or school becomes prioritized over leisure, with many households accepting this hierarchy (Ribak, 2001). How are these practices established? How are they negotiated or how do they change over time? Are households with one computer scheduling Internet time? If so, what is this process and who is responsible? The coordination and scheduling of Internet use is rather fuzzy; is there a daily routine or is it unpredictable (Frohlich & Kraut)? As well, how prevalent is the existence of multiple computers with Internet access in the home? Can multiple computers with Internet access address issues of contention among household members? Does this promote more individual use rather than collective household use?

Parental roles are also important. The presence of children in the household adds to the responsibility of parents in terms of Internet use. Perceptions of the Internet shapes parental concern over what children may be doing online, and how much time they are allowed to spend playing games, surfing, or chatting becomes an issue for many parents. There is little detail on who is responsible for children's Internet use within the household. One could speculate that women may be more responsible because they are the primary caregivers. However, it can also be said that men might be responsible for governing household technology such as the Internet (as technology is said to be masculine). It is difficult to say as there is little research on whether one parent is solely responsible; studies generally discuss the parents collectively (Frohlich & Kraut, 2002).

The Domestic Division of Labour

Household roles encompass not only gender roles, but also the roles of parents and children, and these roles are also framed by domestic labour. The word domestic is often associated with unpaid work in the household or homemaking, which is divided by the different jobs that women and men do (Habib & Cornford, 2001). Domestic labour (unpaid work) involves such tasks as cooking, cleaning, washing, shopping, emotional care of the husband, and child care (Wajcman, 1991). The household division of labour often presumes that women are responsible for this domestic work (West & Zimmerman, 1987) as gender is important in household maintenance and how domestic work is allocated (VanEvery, 1997). Women do more work in the home than men (Hochschild, 1989; Luxton, 1980; Robinson & Godbey, 1997; Shelton & John, 1996), and the amount of domestic work increases for women with the presence of spouses and children (McMahon, 1999; Wajcman). Men are considered helpers rather than sharers in the domestic sphere (McMahon), indicating that domestic work is still perceived as women's responsibility.

Considering the differences between women and men on time spent on household responsibilities, it is worthwhile to consider what the implications are on household Internet use. The interactive processes between husband and wife, and the gender ideology (Komter, 1989) that rests within the home, are important factors to consider when examining the domestic division of labour. While not every household is identical (Hochschild, 1989), depending on race and class (Calliste, 1996; Cohn, 2000; McMahon, 1999), there are overwhelming similarities between heterosexual households.

Feminist literature concerning technology in the home is often useful as a framework because it focuses on the importance of social roles, the hierarchy of these roles, and the relationships of power between women and men in relation to technological skills and use (Cowan, 1983, 1987, 1999). There are often expectations that domestic technology will be labour- and time-saving devices that alleviate women's domestic responsibilities, but this has not been the case (Wajcman, 1991). As the Internet in the household has been discussed within the context of domestication, it is useful to consider some of the previous arguments concerning domestic technology such as the washing machine, microwave, dishwasher, and so forth, and how these affect household members. Is the household Internet any different? If indeed the Internet has become domesticated, we need to consider what this really means to household members, and whether the household Internet exacerbates gender stereotypes and the domestic division of labour or challenges them. What further expectations are there upon women and men in the household with the presence of the Internet?

Given that women are primarily responsible for domestic labour, women will have less time for Internet use. In terms of time available, women with children spend less time communicating and searching for information than men do (Kennedy et al., 2003). Time is an important factor when considering household Internet use. Domestic labour takes time, and therefore less time is available for those responsible for domestic work. Previous research has shown that both women and men with children at home spend less time talking on the phone, reading the newspaper, watching television, and attending cultural events (Robinson & Godbey, 1997). Since women are the primary caregivers of children in the home, Internet use in the home should reflect this status. For example, seeking support from other mothers and offering support through e-mail, Listserv, and instant messaging are important to mothers (Bakardjieva & Smith, 2001; Miyata, 2002).

Furthermore, women's use of technology in the household is often functional so that work is done more efficiently and quickly (Frissen, 1992). Women tend to use it more instrumentally in such instances as helping children with homework and communicating with family and friends, thereby using it as a tool (Singh, 2001). Women are less concerned with mastering the technology or using it for recreation—as a toy—than men are (Singh; Turkle, 1984). Therefore, gender and household roles play an important role in household Internet use. Needless to say, class and race are important as well, yet these are rarely discussed as contextual within the literature.

As well, the kinds of information that women seek online also reflect their caregiver status. More women than men seek health information online, with women twice as likely to seek health information for their children (Shade, 2004). Women's responsibility as caregivers is clearly reflected in the kinds of information they seek online. However, existing literature does not seem to make the connection between domestic responsibilities and Internet use, or it does not present the connection as important or relevant.

FUTURE TRENDS

What also needs to be considered is the flip side of the situation, or how the presence of the Internet in the home has changed or challenged the current structure of the household. For example, De Haan and Huysmans (2002) argue that "home Internet users spend two hours less on paid work and almost two hours less on childcare and domestic tasks" (p. 83), and they claim that Internet users have more free time than nonusers. However, it is not clear why; does using the Internet in the household save time on other tasks? Do households lower their cleanliness standards? Other researchers indicate that parents who are users of the Internet spend more time on child care, less time sleeping, and more time on hobbies (Fu, Wang, & Qiu, 2002). Some researchers (Cranmer, 2000; Livingstone, 1992; Wheelock, 1992) have examined how individuals negotiate (and renegotiate) their gender identity in relation to technology and other household members, which is important in understanding the reciprocal relationship between people and (in this case) the Internet.

Additional research using interviews and participant observation would be useful in understanding the modern household and Internet use, and would situate broader processes into the domestic context (Morley & Silverstone, 1990). As Shade (2004) argues, quantitative data only presents a snapshot of the big picture in terms of the factors affecting household Internet use. How do social meanings of the household Internet come into being? Therefore, the goal of future Internet studies should move beyond quantifying and predicting Internet use (Singh, 2001) to a more comprehensive analysis that involves recognizing the contexts, both micro and macro, of household Internet use.

CONCLUSION

Existing literature focuses on who uses the Internet, how often, and in what way, but gives little on why it is used within the household context. The existence of roles and expectations, formulated around gender, race, and class, and the division of labour are clearly factors that must be examined to understand the diversity of household Internet use. Clearly, when studying a household technology, domestic context is important.

KEY TERMS

Domestication: Refers to the process of adapting something to the household. For example, pets are tamed or trained to adapt to being in a household. In relation to technology, it means adapting the technology to suit the routine and expectations of the household and its members.

Domestic Labour: Refers to unpaid jobs or tasks relative to the household that are divided up between women and men. For women, such jobs include cooking and baking, laundry and cleaning, child care, and emotional care giving. For men, such jobs include yard work, and home repair and maintenance.

Domestic Technology: Refers to specific types of technologies that are located in the home and used in relation to daily household chores or responsibilities. These include washing machines and dryers, refrigerators, microwaves, ovens, and so forth.

Gender: Refers to performative, socially constructed scripts of women's and men's behaviour and characteristics that are deemed either feminine or masculine. These characteristics are culturally and historically specific, and are not the same as biological sex.

Household: Refers to where people primarily reside and is used to reflect the diversity of family types in our society today. The term family comes with much cultural baggage and denotes a heterosexual nuclear family. There is not one monolithic type of family but many different family arrangements (depending on class and race as well as sexuality) including single parents; gay, lesbian, and bisexual families; extended families; and so forth. As well, home denotes a safe haven or space, which is not necessarily the case given the prevalence of domestic violence and abuse.

Household Roles: Refers to such roles as mother, father, sister, brother, and so forth, which come with expectations of behaviour and responsibility based upon gender and hierarchy. For example, mothers are expected to be the primary caregivers to children. As well, Internet use by either parent for work may be deemed as more important than leisure use by children.

Internet: Refers to things people do online such as communication (e-mail, instant messenger, and so forth), information seeking, commerce (purchasing products), and entertainment (games).

Gender and the Internet User

University at Buffalo, USA

INTRODUCTION

Civilization has seen an explosion of information technologies over the last one hundred years. The telephone, radio, television, and Internet have entered the lives of men and women at work and home, becoming the main forms of communication and entertainment. Unfortunately, early adopters and creators of these technologies were men. Women, working primarily in the home, were not exposed to these technological innovations until husbands or fathers brought them into the home. Oftentimes, wives and daughters viewed these "contraptions" as intrusive to the harmony of the home. Therefore, in order to appeal to the widest possible audience these information technologies were adapted, mostly by corporations, to appeal to women through aesthetically pleasing design, creative programming, and product marketing (Shade, 2002). By the end of the 20th century, the television emerged as the electronic hearth. Here the family gathered, shared their day, and engaged in entertainment or debate (Tichi, 1991). Today Americans are spending less time in front of the television and more time in front of the new electronic hearth—the Internet. The average American spends close to three hours on the Internet per day, exceeding the number of hours spent watching television by 1.7 hours (Nie, Simpser, Stepaniknova, & Zheng, 2004).

The Internet has followed a diffusion of innovation pattern similar to all its predecessors, beginning as a communication tool for white, male scientists to share ideas, eventually being adopted by young male "inventor-heroes" who manipulated and improved it. These improvements motivated white businessmen to use the Internet to improve profits and productivity, gather information, and entertainment. In the end the computer, and as a result the Internet, left the man's world of work and entered the woman's domain of the home. Slowly, over the last ten years it has made a subtle impact on the lives of American women.

BACKGROUND

Over the first ten years of the Internet's life researchers have attempted to answer a number of questions about equity of access, gendered use of the Internet (both psychological and cognitive differences), and the impact of these answers on society. This article provides an overview of the community of Internet users and discusses these gender differences. The answers may help realize the goal of a genderless virtual world where all citizens participate equally regardless of age, race, creed, or gender.

Demographic Data

Although IBM first introduced personal computers for the home in 1981, they did not become commonplace until after 1994 when Netscape introduced their Internet browser, Mosaic. During the first six years of its commercial life the design and use of the Internet was dominated by men (Bimber, 2000; Ono & Zavodny, 2003). Since then women have slowly surpassed men to account for 51% of the Internet population (Pastore, 2000). In 2004, 64% of all homes in the United States had Internet access (Harwood & Rainie, 2004). However, there are still age and gender disparities among Internet users.

In 2004 access by age group showed the largest group of Internet users to be 35 to 54 year olds (45%), followed by 18 to 34 year olds (37%), with 55+ being the smallest group at 18% (Mediamark

Research, 2004). By January 2005, the 18 to 29 year olds had surpassed 30 to 49 year olds as the largest age group of Internet users (Pew Internet & American Life Project, 2005). There are virtually no gender differences in terms of the percentage of men and women using the Internet, until the senior population is analyzed. In 2003 the number of female seniors using the Internet reached 49%, up from 40% in 2000, but they still lagged behind senior males (Fox, 2003). One interesting gender difference deals with seniors who are *not* using the Internet. According to a survey conducted in 2002 of non-Internet users 61% of women vs. 49% of men said they would never use the Internet (Lenhart, 2003).

As for children, USC's Annenberg School found that 98% of online youth ages 12-15 used the Internet in 2003, up from 83% in 2000. This same study showed that 97% of online teens ages 16-18 used the Internet up from 91% in 2000 (Cole, Suman, Schramm, Lunn, & Aquino, 2004). A report published by the National Center for Education Statistics reported that 58.5% of children ages 5-17 used the Internet with no gender disparity (DeBell & Chapman, 2003). However, there are socioeconomic and access inequalities in Internet use. Those children living in households with higher family incomes and those with more highly educated parents were more likely to use computers and the Internet than those living in lower income households and with parents who were less well educated.

Internet Connectivity

While women's use of the Internet has reached parity with men there are still connectivity disparities concerning location (work, home, other), age of equipment, type of equipment, and connection speeds. A recent survey conducted by Mediamark Research indicated an equal percentage of men and women connect to the Internet only from work while a slightly higher percentage of women connect only from home, 51% women vs. 49% men (Mediamark Research, 2004). Another recent survey conducted by Pew in 2003 found that a gender gap existed between men and women who connected from other locations. Fifty-four percent of men vs. 46% of women connected from locations other than work or home (Harwood & Rainie, 2004). Men were more likely to connect from a friend's house while women were more likely to use a library. However, of those over 65, 90% of them connect from home compared to 10% from work (Fox, 2003).

When one compares age, location, and gender we see no remarkable connectivity gap between boys and girls (DeBell & Chapman, 2003; Jones & Madden, 2002). The most recent and comprehensive survey, conducted in 2001 by the National Center for Educational Statistics (NCES), shows that overall 78% of children ages 5-17 connect to the Internet from home compared to 68% who connect from school.

Aside from location, with home being the most convenient, the age of the equipment used to connect to the Internet is also important. Not surprisingly, women tend to have older and slower equipment. A 2001 survey by the U.S. Census Department found that on average women's computers were three years older then men's computers (U.S. Census Department, 2001). It also found that 44% of men owned a computer less than two years old vs. 37% of women.

Wireless, hand-held devices, like cellular telephones, PDAs, and pocket PCs are the next wave in information technology. These technologies are positioned to become an integral component of ubiquitous technology that provides instant access to information anytime from anywhere. Unfortunately, to date, they are disproportionately used by men with 65% men to 35% women (eMarketer, 2003).

The connectivity speed can often dictate the types of activities being conducted online. Multimedia presentations and images are large files that require a computer with enough memory capacity and the Internet connection bandwidth to view and download. Therefore, the online experience is better if the connection speed is faster and more robust. The latest connection type, broadband, is slowly overtaking the market accounting for 41% of Internet users. According to a 2003 survey by Nielsen/NetRatings, 52% of broadband subscribers are male compared to 48% female (eMarketer, 2003). This is good news for gender equity since the prevalent theory is that a quicker connection speed allows the user to explore the Internet for itself rather than for specific information.

Internet Use

How much time are men and women spending on the Internet? A 2001 National Geographic Survey (NGS) found that men spend 10.41 days/month finding information on the Internet while women spend 7.33 days/month (Kennedy, Wellman, & Klement, 2003). What are Internet users doing online? According to the 2004 Pew Internet & American Life project the most popular online activities conducted from home were:

- E-mail (45%)
- Getting news (27%)
- Checking the weather (20%)
- Looking for political information (13%)
- Instant messaging (12%)
- Watching video clips or listening to audio clips (11%)
- Online banking (9%)

Pew noted men are more likely to use the Internet to get news and sports scores while women are more likely to seek health and child care information (Fallows, 2004).

While e-mail is used by almost all Internet users, the Stanford Center for the Quantitative Study of Society found that women use e-mail and instant messaging for social purposes more than men, while men spend slightly more time browsing, checking out newsgroups and in chat rooms (Nie et al., 2004). Women spent 27.53 minutes per day using e-mail compared to 23.50 minutes each day for men. On the other hand, men spent 22.11 minutes per day browsing the Internet compared to women who spent 15.18 minutes per day (Nie et al., 2004).

Accessing news online is an activity more likely to be carried out by males than females. In 2004, 33% of men and 25% of women went online for news. When comparing education, age, and gender we see very different results. Approximately 74% of male college graduates under 40 regularly go online for news compared to just 45% of female college graduates (Pew Charitable Trust, 2004).

Although men and women are engaged in the same online activities, the way they interact with technology varies by gender. A 2000 National Geographic Survey (NGS) found that 60% of women compared to 54% of men felt that the Internet, specifically e-mail, brought them closer to their immediate and extended families. Meanwhile, the General Social Survey 2000 and 2002 (GSS) showed that women were using e-mail to maintain social networks while men were using it to maintain business relationships (Kennedy, Wellman, & Klement, 2003). Both NGS and GSS show three areas where men and women differ in Internet use: communication, information, and recreation. Women use the Internet to build communication networks while men use it to gather information and recreation.

Gender Differences

The diffusion of information technologies, like the computer, start with the early adopters who have traditionally been men. Over time they are adopted by women due in large part to economic necessity. This is because men have the social standing and means necessary to adopt new information technologies early. As these men interact with their friends, co-workers, and employees they provide the communication channel necessary to introduce the innovation to the early majority. Because women are usually not members of these two groups, early adopters or early majority, they fall under the late majority, coming to the innovation out of economic necessity; or they have no interaction with the innovation due to limited financial resources.

Despite gender parity in terms of percentage of Internet users and time online, women do not have similar experiences to men. Recent research has found that cognitively women and men interact with technology differently. Men process information visually, through the right side of the brain, while women process information textually, through the left side; therefore, men navigate the Internet more effectively with a mouse while women navigate best with hypertext links (Calvert, Mahler, Zehnder, Jenkins, & Lee, 2003; Rodgers & Harris, 2003). Low self-efficacy and anxiety are psychological issues that negatively impact a woman's experience with the Internet (Barron, 2004; Torkzadeh & Van Dyke, 2002; Zhang, 2004). As a result they are less confident in pursuing careers in programming and systems design (Lynn, Raphael, Olefsky, & Bachen, 2003). Women tend to be introverted, using the Internet to connect and find emotional support, while men are extroverted, using the Internet for stimulation either through gaming or pornography (Hamburger & Ben-Artzi, 2000). How the Internet is viewed also varies by gender. A 2002 study of children ages 11-16 showed that boys saw the Internet as a toy to be "tinkered" with and explored for itself while girls approached the Internet as a tool to complete tasks (Colley, 2003).

The best method of minimizing computer and Internet anxiety is to promote technology fluency through hands-on training (Broos, 2005). The more someone is familiar with a technological tool the higher their self-efficacy scores. Women, especially young girls, should begin creatively approaching the Internet through programming and design activities (Barron, 2004). These activities allow them to develop technological fluency and in turn minimize anxiety. Both boys and girls find the most effective teaching methods to be independent practice, friends, parents, and classes. Therefore instructors should create tutorials that address both male (visual) and female (textual) learning styles (Mumtaz, 2001). If young girls do not see the Internet as a toy to be deconstructed they run the risk of always having difficulties with emerging technologies (Torkzadeh & Van Dyke, 2002).

Internet video games are another tool that help young girls become computer literate, improve self-efficacy, and develop cognitive abilities like spatial orientation (Lynn et al., 2003). Further research by the organization Children Now found that 89% of the top selling computer video games contained either violence or subtle sexual content. Those games specifically designed for girls reinforce traditional gender stereotypes with characters like Barbie and Bratz (Glaubke, Miller, Parker, & Espejo, 2001). Game designers should develop games for girls that promote teamwork, transition with text, and avoid violence (Glaubke et al., 2001).

One way to keep adolescent girls interested in deconstructing technology is to show the connection between computers/Internet and traditional interests (Lynn et al., 2003). For example, interactive Web sites that utilize design software to create clothing, works of art, or animation teaches girls how to use complex technology, become motivated to use it, and find it relevant to the achievement of their goals. Once young women experience the power of the Internet they will want to become part of its future. This is also the point where women who are in technology professions need to consider becoming role models and mentors to aspiring female innovators (American Association of University Women, 1999).

FUTURE TRENDS

The future Internet will most likely not resemble the current Internet. As ubiquitous technology enters mainstream society, information will become accessible anytime, anywhere, and through a multitude of devices. Our stoves will connect us to recipes; our refrigerators will e-mail the local grocery store to hold milk and eggs for pickup; and televisions, the old electronic hearth, will be replaced by multimedia centers complete with Internet access to the latest movies, music, and online college courses. Streaming video will become an Internet staple due to high-speed broadband or other, faster connections. Textual blogs will give way to video blogs and everyone will have their fifteen minutes of fame. Eventually the lines between work and home will blur further and leisure time will include the Internet as an activity.

Will women play a major role in the development and use of emerging Internet technologies? A larger number of women will need to enter computer science professions in order to become the innovators and early adopters of emerging technologies. Teachers will need to adapt teaching styles and employ problem-solving skills familiar to young girls. The media will need to move away from the stereotype of computer expert as nerdy, lonely boy/man. Finally, parents will need to engage their daughters with science and technology that is of a gender-neutral nature. In combination all of these factors will help young women become comfortable with the hardware and software used to create emerging technologies.

CONCLUSION

The Internet has helped women expedite tasks that would have taken them away from family, careers, and leisure time. Now they can order dinner, bank online, grocery shop, download do-it-yourself tutorials, and apply for a mortgage from the comfort of their homes while doing traditional tasks like childrearing and housework, things women will always do.

With the numbers of young women online fairly consistent with the numbers of young men, it could be said that the gender gap has been closed. But has it really? Women continue to trail behind men in computer related courses and careers and gender related privileges are still being replicated on the Internet through things like pornography, male oriented terminology and cyber harassment (Gorski, 2003; Spender, 1996). Family, educators, the government, and the media need to encourage young women to enter into technological fields of study and designers must begin creating either female friendly or gender-neutral hardware and software. It is through these measures that the next generation of women will feel comfortable and confident enough to become the next great technology innovators.

KEY TERMS

Bandwidth: The information carrying capacity of a network or connection to the Internet.

Blog: (weB LOG) A personal, interactive journal that is available on the Web.

Cyber: Prefix to words used to indicate an association to the Internet or virtual world.

Cyber Harassment: Threatening behavior towards someone using the Internet.

Diffusion of Information Technologies: Based on Everett Rogers' *diffusion of innovation* theory that innovation is communicated through certain channels over time among the members of a social system.

Digital Divide: Term used to refer to the gap between those who have access to technology and those who do not.

Gender Gap: Unequal treatment or access to a product or service due to a person's gender.

Hand-Held Devices: Hardware used to access the Internet wirelessly such as personal digital assistants (PDAs), cell phones, and MP3 players.

Ubiquitous Technology: Information is delivered anytime, anyplace, anyway. Futurists see an Internet that is embedded into appliances, consoles, clothing, watches, cars, etc. that can be used to access information, complete a task, or entertain. Eventually information technology is seamlessly woven into our daily lives to the point that going online is a continuous state of being.

Gender and the Use of DSS in the Australian Cotton Industry

Dale Mackrell
Griffith University, Australia

INTRODUCTION

This article provides an overview of an ongoing study that explores farm management practices by Australian women cotton growers using farm management software, most particularly agricultural decision support systems (DSS). The research methodology is interpretive with multiple case studies of women cotton growers and industry professionals. Participants were selected on the basis of indicating an awareness of environmentally responsible and high technology farming practices. Data collection was principally by semi-structured in-depth interviews. The study is informed through a theoretical framework of structuration theory as a metatheory for probing the recursiveness of farm management and technology usage, and diffusion of innovations theory as a lower-level theory for analysing the characteristics of the software.

Evidence from the study suggests that farm women intentionally select specific software modules for implementation depending on the attributes of the software. Further, while computer-based farm management systems, including agricultural DSS, are recognised media for technology transfer of industry research to farms, the study found the cooperation of farming partners to be essential in influencing effective reconstruction of farm management practices and software usage. The study also explores gender homophily, in particular the relationship between husband and wife as partners in a cotton farm business. It is apparent that gender differences and inequalities are still prevalent and indicative of "gender heterophily." Nevertheless, in the main, communication between parties is harmonious, empathetic, and by definition homophilous, thus ensuring effective information exchange.

A notable benefit of using decision support software is an enhanced critical awareness of existing farm management practices. Further, the women are empowered by increasing confidence to contribute in enterprising ways to a greater range of farm management tasks and to more innovative applications of computer-based farm management tools.

BACKGROUND

The cotton industry in Australia is thriving. Nevertheless, cotton management is becoming increasingly complex with the need to sustain reliable crop production while making the best use of water and soil resources, to utilise effective pest and weed management, as well as to limit environmental impacts (The Australian Cottongrower, 2004). Innovative technologies, such as the agricultural DSS, *CottonLOGIC,* are considered keys to the adoption of sustainable farming systems (Hearn & Bange, 2002).

While the literature is sparse in the specific research domain of my study, there has been extensive research in categories such as DSS and farm management, and gender and information technology (IT). Although the portrayal of women in farming has been the subject of many studies both in Australia and overseas, the range is more limited when the study includes the use of computers. One study of rural women embracing computer usage was by Stewart (1997). For her PhD, she explored the gendering of interactive communication technologies (ICTs) in use on Australian family cotton farms. Stewart found that farm women's lack of confidence as controllers of data meant that they often avoided responsibility for utilising computer-based information systems for decision making purposes. Even so, Stewart found evidence that many rural women were increasingly aware of the possibilities of computers for decision making, encompassing new and innovative farm management practices.

In her research into the lives of Australian farm women, Alston (1995) argues that farm roles have developed based on gender stereotypes and that traditional divisions of labour prevail. Male farmers are participants in the "more important" public sphere of outdoor work while farm women have become associated with the less visible private sphere of housework and children. This "domestic work has come to be devalued because it is unpaid and not directly geared to agricultural production and the marketplace" (Alston, 1995, p. 24). The theme of the "invisibility" of women farmers emanated from research by Sachs (1983) and has resonated through feminist studies of Australian rural women. Further, James (1989) claims that despite the increase of legal farm partnerships, the participation of women in decision making on the Australian family farm is unclear. Moreover, there is evidence that divisions of responsibility in farm management, largely based on gender, may actually contribute to poor decision making (Daniels & Woods, 1997).

The value of women's work has engaged sociologists beyond the farm gate. Sharpe (1992) in a reader on human societies edited by Anthony Giddens, discusses the difference between paid work outside the home and unpaid domestic work in a British urban setting. She argues that women's self-esteem may become bound up with the care and services provided to family members, and notes that "this unrecognized work is in effect the service and maintenance of the workers of today and tomorrow. It *is* related to the external world of production, but indirectly" (Sharpe, 1992, p. 56).

DISCUSSION

The following section outlines preliminary findings from the study in three papers written by the author (Gartshore, 2003; Gartshore, 2004; Mackrell, 2005).

Software Attributes and their Relevance

In analysing the use of an innovation such as *CottonLOGIC*, Gartshore (2003) utilises the concepts of divisibility (or modularity) and implementation costs, in particular, intellectual outlay from the environmental model of technology diffusion (Vanclay & Lawrence, 1995). While *CottonLOGIC* is a software package that consists of several modules, for the most part, the women cotton growers deliberately selected modules pertaining to the recording of field and spray operations. These modules enabled them to record the usage of fertilisers, herbicides, pesticides, and so on. This meant that the women were better informed particularly for managing costs of production and improving sustainability. These modules were also envisaged as useful by one of the women cotton consultants whose aim is to provide a more complete record of clients' farming operations.

As elaborated further in the paper (Gartshore, 2003), intellectual outlay takes into account, (1) complexity of the innovation, (2) collaboration by stakeholders, (3) redundancy of effort, and (4) *CottonLOGIC* course participation. Participants in the study acknowledged the varying intellectual expense in the implementation of *CottonLOGIC*. While the *CottonLOGIC* training courses were greatly appreciated, and went a long way to addressing the computer deficiencies of users and the agronomic complexity of the software, the individualistic needs of the women meant that there often remained a mismatch between the skills required to operate the software and the skills possessed by many cotton growers. Further, the notion of redundancy appeared important as an influential factor in the adoption or non-adoption of *CottonLOGIC*. Many participants clearly stated their objections to re-keying the insect count data for the insect prediction models that had been previously entered into *CottonLOGIC* by crop scouts or cotton consultants. As well, communication with partners and agronomists was deemed desirable in achieving optimum results.

The following extract from an interview with Selma, a cotton grower, supports and illustrates the generally harmonious and productive rapport reiterated by women cotton growers. It highlights the importance of collaboration and cooperation in a family farm setting, with few inklings of "invisibility" and of being undervalued.

We work as a team really. I'm more focussed on the administration side of things. X [farm partner] is more focussed on the day-to-day running, and *keeping out of the office which he shouldn't do. He needs to be more involved.*

Overall, the farm women interviewed demonstrated a high level of confidence in their ability to use computer-based farm management systems and a critical recognition of the software's functions. Furthermore, it appeared that the use of *CottonLOGIC* by farm women was instrumental in augmenting their level of awareness, understanding, and interpretation, thus provided them with additional confidence to challenge existing practices. This was exemplified in a statement by a Diane, a manager of a cotton service business:

If women can do CottonLOGIC…they also have a far better exact knowledge of what's happening on the farm so therefore are far better equipped to have a very equal involvement in decision-making whereas a lot of decision-making happens in the garage [shed] …

Vanclay et al. (1995) studied the crises in Australian agriculture, especially the issue of environmental degradation during the 1990s, from a critical rural sociological approach. They analysed the various theoretical perspectives in use in rural extension including the technology transfer model, premised on diffusion of innovations theory (Rogers, 1983, 1995, 2003). In attempting to examine aspects of the diffusion process, Vanclay et al. considered factors affecting the non-adoption of technology including divisibility and implementation costs. Their research found that current thinking is inadequate in addressing existing environmental problems. In particular, the author drew from their work the differentiation between technological innovations of a commercial nature and those more environmentally focussed.

Technology Transfer from Researcher to Farmer

Building on the concept of communication, applicable to both structuration and diffusion theory, Gartshore (2004) investigates the communication process for informing cotton growers of the latest science available from research. Informing science can transpire through social and technological communication channels. Even though the focal point of the study is the agricultural DSS, *CottonLOGIC*, the cotton industry engages other channels of communication such as verbal, fax, Web, electronic and standard mail. Filtering of vital information demonstrates cooperation by the farm partner who spends time in the farm office rather than in the fields and provides opportunities to translate new knowledge from scientific research into changing practices for both farm management and technology usage. Thus cotton growers are better informed particularly for managing costs of production and improved sustainability. As Renee, a cotton grower, intimated:

I'm informed and if I relay it back to him [farm partner], it's both of us knowing what's going on.

One of the initial influences for the author in pursuing the technology transfer aspect of agricultural DSS was studies by Cox (1996), a rural researcher working in country Australia. While some of the findings by Cox had aroused intense controversy and debate at the time, the author was particularly interested in his work on communication, most specifically the use of DSS where he states that "the criteria for success…should relate to the critical insights gained through improved communication of the different perspectives of researcher and farmer" (p. 376).

Social Networks and Teamwork

Mackrell (2005) examines gender homophily in interpersonal networks within the context of Australian family cotton farms. While traditional gender divisions of labour exist for whatever reasons on the family farm, at a professional level within the industry, gender distinctions are less apparent. This confirms past research (Powell & Johnson, 1995) that associates formal training, as for agronomists and industry service personnel, with improving women's confidence as independent decision makers and managers. This also endorses the social constructivist perspective that gender is a socially constructed concept rather than biologically determined.

The paper by Mackrell (2005) validates previous research that suggests that communication networks in organisations are largely clustered by gender and that same gender networks are associated with effective communication (Brass, 1985). It is apparent from the study by the author that while informal all-male networks are a valuable media for knowledge exchange for the men, the women have to strive harder to overcome occasional hostile reactions before establishing more formal social contacts such as *WinCott* (Women's Industry Network Cotton). The author argues that while gender homophily exists within the single sex networks, it would be more accurately described as "gender heterophily" between the all-male and all-female networks.

In the setting of the cotton farm, despite the existence of "gender heterophily" through disparate gender relations as in the traditional gender divisions of labour, a more compromising and harmonious atmosphere prevails to facilitate effective communication. This confirms research that a certain degree of heterophilous communication might be the basis of positive "creative dissidence" or synergy between the interacting parties (Sumberg, Okali & Reece, 2003, p.744) and that "heterophilous individuals who have high empathy are, in a psychologist sense, really homophilous" (Rogers & Shoemaker, 1971, p.14).

Homophilous communication is crucial for effectively transmitting knowledge about the features of *CottonLOGIC* as well as its novel possibilities for improved self reliant farm management, the value of which is encapsulated in a statement by George, an independent cotton researcher:

DSS [such as CottonLOGIC] have the potential to put the management of diseases back into the hands of the people who live there, so far it's mainly the male partners, the man. But increasingly both, if they are given this sort of technology [CottonLOGIC] where they can put all these specialist things into context, by that simple process, they take the excess power away from the expert and back into their own hands where it belongs. And they have the ability through technology to weigh options.

As previously mentioned, Stewart (1997) in her PhD study, explored the use of ICTs by farmers on Australian family cotton farms. Her research, informed by the conceptual framework of Connell's theory of the social construction of gender, identified gendered structures of labour and power. She found that women were constrained in the use of technology by the acceptance of dominant ideal constructs of masculinity and femininity. In her conclusion, she foresees:

The greater take-up rate of computers by farm women than by their husbands suggests on the face of things that some women at least are being assisted by ICTs to develop more equal partnerships with their husbands and members of their extended farming families than were possible in the past ... (p. 342)

However Stewart warns this may be only temporary and may change as farm men become more computer literate. Mackrell (2005) has not identified this tendency.

FUTURE TRENDS

Future trends are offered from both practical and theoretical perspectives. There is considerable current debate amongst stakeholders such as farmers, scientists, researchers, DSS developers, and government as to the future direction of *CottonLOGIC* (Hearn et al., 2002, p. 49). Should the DSS development team concentrate limited future resources on the record-keeping modules or the prediction modules for decision support, or both? Indeed, findings from the study have already contributed to a business plan commissioned by the CRDC in 2004.

The contribution to theory may also have significance. The use of sociological theories to explore gendered concepts has proved to be a challenge since neither diffusion theory (Rogers, 1983, 1995, 2003) nor structuration theory (Giddens, 1984) explicitly address gender relations and matters of patriarchy. Although both theories overall provide a rich framework with which to inform the topic, the concept of gender is too important to ignore and is a notable omission, especially from diffusion theory.

In addition, Australian feminist rural researchers, Pini and Previte (2004) provide inspiration to address the methodological and epistemological aspects of the study with their view:

... feminist research is not simply research on women or gender, but research on women or gender which acknowledges and seeks to address gendered injustice. Feminists are concerned, not with simply obtaining knowledge, but on the process by which knowledge is collected and the way in which knowledge is used (p. 2).

CONCLUSION

The cotton industry endorses the use of innovative technologies such as agricultural DSS to enhance sustainable farming systems. This study in seeking to better understand the constructs associated with the adoption and implementation of *CottonLOGIC* by rural women, has the potential to generate improved resource management on family cotton farms with flow-on benefits to the Australian rural sector.

Evidence from the study reinforces the existence of gender differences and inequalities in rural Australia. Nevertheless the environment is dynamic, with transformations in social structures occurring. Women are taking the future into their own hands. With confidence gained through involvement in interpersonal networks, participation in training, and the acquisition of technological skills, they are shaping and reshaping their lives. In particular, computer-based software such as *CottonLOGIC* is instrumental in enabling them to challenge and influence the reconstruction of existing farm management practices and technology usage. This reflects a central principle of structuration theory concerning the recursiveness of social life.

KEY TERMS

CottonLOGIC: *CottonLOGIC* is a software package of decision support modules for assisting cotton growers and their advisors in the tactical management of cotton pests, soil nutrition, and farming operations. It enables the recording and reporting of insect populations, weather data, crop yields and field operations such as fertiliser, herbicide and pesticide applications, as well as the running of prediction models to forecast pest density and soil nutrition. It is being developed in Australia as an advanced farm management tool by the Commonwealth Scientific and Industrial Research Organisation (CSIRO) and the Cotton Cooperative Research Centre (CRC), with support from the Cotton Research and Development Corporation (CRDC).

CRDC: The Cotton Research and Development Corporation is a partnership between the Australian Government and the Australian cotton industry to provide leadership and investment in research, innovation, knowledge creation, and its transfer.

DSS: While there is no universally accepted definition, decision support systems may be identified as interactive computer-based systems that support decision makers.

Farm Management: Factors include decision making, production, marketing, human resources, financial, risk and change management.

Gender Homophily: Recent research has identified homophily in a variety of characteristics such as gender, age, class, race, and occupation, and in a range of social settings such as organisations, cultural communities, and families (McPherson, Smith-Lovin, & Cook, 2001). However there is no evidence of previous use of the term "gender heterophily."

Heterophily: Heterophily, the mirror opposite of homophily, is the degree to which pairs of individuals who interact are different in certain attributes (Rogers, 1983, 1995, 2003).

Homophily: Homophily, the tendency of people in friendship pairs to be similar, was recognised before the 1900s (Rogers, 1983, 1995, 2003).

Information and Communication Technology: This refers to the range of technologies that facilitate communication. They include telephones, mobile phones, fax machines, and personal computers which may or may not be connected to the Internet.

Technology Transfer: This principle of science-based intervention, also termed the "transfer of technology" push, has been criticised for ignoring the socio-economic context.

WinCott: The Women's Industry Network Cotton was formed in 2000 to provide support, information and resources to encourage and empower women in the Australian cotton industry to have skills, confidence and an informed voice.

Gender Bias in Computer Courses in Australia

G

Iwona Miliszewska
Victoria University, Australia

INTRODUCTION

The participation of women in science and, more recently, in information technology (IT) has engaged researchers for more than 20 years. Despite extensive research and numerous practical interventions designed to address the relative dearth of women in IT, the problem persists. This is an important question since computing and computer competence are critical to ongoing developments of the "information revolution." Evidence from around the world suggests that despite female predominance in undergraduate enrolments (59% in Australia, 55% in America, and greater than 50% in many European Union countries), women are reluctant to pursue IT study at tertiary level (Rees, 2001).

Initial approaches to reverse this trend centered upon notions of equality and affirmative action, since the lack of significant numbers of females in the discipline was seen as inequitable. To alleviate the problem, intervention programs aimed at women have promoted information on technology-related careers, provided experience of computing work, and highlighted female role models. Other initiatives focused on helping women develop skills, attitudes, or background knowledge that women were thought to lack. These affirmative action measures, while commendable in fostering gender equality, were not sufficient in that they often served to reinforce the conceptions of IT as a masculine domain and, consequently, failed to attract women to IT. This suggests a need for an alternative approach—a reconceptualization of IT into an environment that women would naturally embrace. Such a need, in the area of tertiary computing education, motivated this study.

The aim of the study was to investigate, from the students' perspective, the perceived problems faced by female computing students at Victoria University in Melbourne, Australia; the study focused on problems related to the learning environment, particularly on direct and subtle gender-related problems encountered in the classroom, and special needs of female students.

BACKGROUND

Gender-Related Issues in IT Education

The underrepresentation and poor retention of female students in IT courses, including computer science, both in Australia and elsewhere, has been well recognized. The already low number of female students enrolling in computer science is usually further decimated by high attrition rates. This situation has often been attributed to gender differences in interests, motivation, experience, personality characteristics, abilities, self-efficacy, and socialization. These differences, which put females at a disadvantage in computing courses, stem from a variety of factors both external and internal to the institution offering the course. External factors include: the popular perception of the male-dominated computing culture, its particularly masculine character and, often, a "geek" image. The internal factors include: inadequate pedagogical techniques, stereotypical attitudes of lecturers and fellow students, and lack of proper institutional support (Fisher, 2003; Miliszewska & Horwood, 2002; Newmarch, Taylor-Steele, & Cumston, 2000; Nielsen, von Hellens, & Wong, 2001).

While external factors lower female students' self-confidence in their computing skills, abilities and accomplishments even prior to entering the course (Lazowska, 2002; Zeldin & Pajares, 2000), internal factors are likely to deepen existing negative impressions even further, and create new ones through:

- **Negative Classroom Experiences:** caused by assumptions of prior knowledge and hands-on experience with computers, stereotypical attitudes and interaction style (often patronising or aggressive) of lecturers, and fellow students

(Lazowska, 2002); lack of structured environment and detailed instructions (Crump, 2001); and, unwanted positive discrimination—in the form of easier assessment for instance (Nielsen, von Hellens, & Wong, 2001)

- **Inadequate Access to Computers in the Classroom:** often dependent on the level of aggressiveness of fellow students (Clayton & Lynch, 2002; Davies, Klawe, Ng, Nyhus, & Sullivan, 2000)
- **Unequal Participation in Class:** females are not: allocated equal time on computers, called on equally in class, assigned equally difficult tasks, or participate in the interaction between lecturer and students as often as males (Levenson, 1999)
- **Lack of Interesting Gender-Neutral Projects in the Course:** the course includes few goal-oriented tasks on which females could work in teams (Weinman & Haag, 1999); lack of problems and examples from diverse disciplines outside of computer science (Blank & Kumar, 2002; Cohoon, 2002)
- **Lack of Role Models and Career Advice:** few female lecturers and tutors, few female fellow students, "invisible" successful career women, stereotypical career impressions and a lack of information about computing as a career (Cohoon, 2001; Crombie, Abarbanel, & Anderson, 2001; Teague, 2002)
- **Inadequate Institutional Support:** lack of special programs that would enable females to learn computer basics and computer jargon, and help them feel comfortable around computers; lack of encouragement and mentoring on the part of the lecturers; lack of institutional support in gender-sensitive teaching (Crump, 2001; Cohoon, 2001)
- **Lack of Peer Support Groups:** lack of interaction between, and lack of support networks among, students in class (Springer, Stanne, & Donovan, 1999).

Despite the existing body of research, there is no consensus on the gender disparity in computer science and, while the reasons why females desert computer science are still unclear, female representation in the discipline continues to decline.

Gender and IT at Victoria University in Melbourne, Victoria

Participation and retention of females in computer science at Victoria University is a particularly elusive issue. Computer science appears to offer an attractive scenario to potential female students—gender-neutral curriculum, attractive career path, and high salary scale. Why then, are the trends in the opposite direction? Despite a range of initiatives created to encourage participation and improve retention of females in the computer science course, female enrolments have declined significantly in the recent years (from 31% in 1994 to 18% in 2004), and attrition rates soared (from 18% in 2000 to 40% in 2003—in the first year of the course alone).

Since various initiatives undertaken over the years failed to impact on these disappointing trends, the underlying problems appeared to reside elsewhere and new research was needed to guide retention efforts. It was decided to conduct a study that would focus on internal factors, particularly the classroom environment: of interest was the possibility of gender bias in the learning environment and its impact on female attrition rates.

Gender and IT: Student Perceptions

The objective of the study was to investigate issues pertinent to the pedagogy and content of computer science courses, as well as the classroom climate, with a goal to make the discipline more inclusive for female students. A multidisciplinary research team was formed in mid 2003 and funding for the study was secured from the government-sponsored Higher Education Equity Program (HEEP).

Four focus groups consisting of two single gender groups and two mixed gender groups were conducted: 32 students representing both genders and all year levels participated. The central topic of the focus groups was gender equity in the computing learning environment; the key question: "Why do female students drop out of the course?" The comments made by students during focus groups centered around issues of gender balance of both students and teachers, course content, resource access and collaborative activities:

- **Gender Balance:** The fact that the majority of students in the computing course were male was of little concern to either male or female students. Similarly, students did not regard the gender of the lecturers as important—competence and good teaching skills mattered. However, female students perceived female lecturers as more friendly and approachable
- **Course Content and Resource Access:** Attitudes to the content of the course were more ambivalent. Although all students felt that the course content was determined by its technical nature, there was some acknowledgment that more alternative "female-friendly" practical course material might have been chosen. However, both female and male students considered that they had equal access to computers in the computer laboratories and that there was no evidence of male dominance or "bullying" in claiming available machines. The suggestion, reported in research literature, that male students tend to "hog" computers and exclude female students was met by all students with utter disbelief
- **Collaborative Activities:** With respect to group work, the only interest that potential group members had in each other was their competence and willingness to work—gender seemed immaterial. Interestingly, all students testified to a truly collaborative approach to group work with the work being shared and rotated within the group to ensure that all members, female and male, gained experience of the differing demands of the project. The recognition of the skills that each member brought to a group project was clearly evident.
- **Further Reasons for High Attrition of Females:** Lack of self-confidence and lack of friendships were considered major factors, as was the overall difficulty of the course, particularly programming subjects; lack of interest in the course from the beginning and family concerns were also perceived as a contributing factor. Female students expressed the need for more support, especially of a social nature. They also perceived a need for students to be better prepared for the university experience

Following the analysis of focus group findings, a survey was developed to seek confirmation of these findings from a wider cohort of computing students and discover other factors contributing to growing female attrition rates. Two hundred and ten students completed the survey: 47 females, and 163 males. The respondents were young: the median age for females was 23, and for males 21 years; they came from all year levels of the course; and, they typified the students in the course, and indeed the University, with respect to their ethnic origin and educational background. Almost 70% of respondents were born overseas, and nearly 56% of respondents spoke only a language other than English at home. Although the majority of students entered the computing course directly after completing high school, 28% of males, and 38% of females entered the course after completing other types of further training.

The survey responses addressed the following issues:

- **Transition to the Course:** Although a greater percentage of female students found coping with study load, finding friends, and balancing study with family and work commitments difficult, the differences were not significant in comparison with male students. Another important transition issue was that of adjustment duration. A majority of all students (78% of females and 84% of males) settled into the course within the first six months. However, male students adjusted much more quickly; nearly 60% of male students took less than two months to settle, as opposed to only 38% of females in the same time period
- **Satisfaction with the Course:** The level of satisfaction/dissatisfaction with several aspects of the course was the same for both genders. However, there were differences with satisfaction with course content. Views were more polarized among female students. A greater percentage of females than males found it satisfactory (43% vs. 31%) but at the same time, more females than males found it unsatisfactory (21% vs. 15%). Significant difference between the genders occurred only

with satisfaction about own performance; male students were more satisfied with own performance than their female counterparts

- **Intention to Quit the Course:** While one-half of the students (53% of females and 48% of males) never considered quitting, the other half thought about it—17% of both females and males alike thought about it seriously. Among various factors that influenced their decision to continue in the course, family encouragement rated highest, especially among male students. No correlation was found between the students' intentions to quit the course and either their educational or ethnic backgrounds. However, a comparison between the intention to quit and the students' current year of study revealed that the intention was strongest among females in their second year of study–nearly 60% of them considered quitting
- **The Issue of Gender in the Course:** More than half of the students of either gender did not regard the underrepresentation of females in the course as a problem; interestingly, fewer females than males (17% vs. 28%) felt that underrepresentation of females in the course was a problem. However, female students tended to agree more that male students "hogged" computers in laboratories; they also preferred not to work with other students, particularly male
- **The Content of the Curriculum:** All students considered the curriculum largely gender neutral and the distribution of agreement was similar for male and female students. Both groups were equally comfortable with voicing their opinions in class and felt that those opinions were received positively. Neither group felt that an equal gender representation in the course was needed to improve their willingness to speak in class
- **Seeking Help:** For females, the most preferred source of academic help was their fellow female students followed closely by female lecturers; male tutors came last. For males, fellow male students were the first choice, followed by male lecturers with female tutors in the last position. When seeking help on personal problems, female students would again firstly turn to their fellow female students. The next three choices of female lecturer, female tutor, and fellow male student were far behind the first choice; male tutor was the least preferred option. Male students, too, nominated their fellow male students as, by far, the most preferred source of help on personal problems; female tutor was the least preferred choice.

FUTURE TRENDS

The overall findings from the study were rather surprising, as they yielded no strong indication of gender bias in the learning environment of the computing course. The focus group moderator emerged from the focus group sessions somewhat baffled having expected answers that would support the original hypothesis of the research study—that the existence of gender bias in the learning environment contributes to high attrition rates of females in computing courses. That thesis was not sufficiently supported. The focus group moderator concluded *the students are telling me that there is no entrenched overall problem: you are doing a good job*. It was a bittersweet conclusion: sweet was the knowledge that the students, both male and female, found their learning environment gender-neutral; bitter was the realization that if gender bias did not drive females away from the computing course, then something else did.

The fact that over one third of female students entered the computing course after completing further postsecondary training, may suggest that this type of training is a good preparation for computer science for females. Conversely, significantly more males than females came to the course straight after high school. This may be a vital clue to the problem of underrepresentation of females in the computing course. It may suggest that the course either does not appeal to high school females, or that the information about the course does not reach them in the first place.

The first year, particularly the first semester, of the course emerged as the 'make or break' period especially for female students. Not only was it an important period with respect to adjustment to the course, but also it was a period most likely to influence most female students' decisions about quitting the course. It appears that staff encouragement mattered little in dissuading female students from quitting, but the support of fellow students was important. Male students highlighted family encouragement to continue with the course significantly more often than females did. Is this a sign of gender bias within the family?

While the lack of female role models in the course was not identified as important, the preference for seeking help from female as opposed to male staff members seems to suggest to the contrary. Is it gender stereotyping, or are female staff members more available to help?

CONCLUSION

This article reports on the findings of a study conducted at Victoria University in Melbourne, Australia, that explored the relationship between gender bias in computing courses and attrition rates of female students from these courses. Since gender characteristics, such as role stereotyping, mathematical ability, interest, and attitudes towards computers were not sufficient to explain the increasing loss of females from computing, it appeared that characteristics related to the IT environment might exaggerate gender differences. Hence, this study was directed at environmental conditions within the control of the University including course curriculum, pedagogical techniques, access to computers in the classroom, class participation, and institutional support.

The findings obtained from focus groups with students yielded some unexpected results. The responses of the students were surprising in terms of their overall assessment of the computer science course, especially against the background of diminishing female numbers. The overwhelming message delivered by all students was that there were no major gender-related problems in their learning environment.

The results of a subsequent survey confirmed most of the focus groups findings. However, some of the survey results contradicted the findings of the focus groups, for instance: equal access to computers in laboratories, and problem-free group-work. Moreover, although female students did not regard the underrepresentation of females in the course as a problem, they singled out their fellow female students as the vital source of both academic and personal help, thereby reiterating the need for female peers in the course.

Transition to the course was identified as a possible factor contributing to high attrition rates of females in computing courses. Not only did the female students take considerably longer to settle into the course, but they also were most likely to drop out of the course after the first year of study. The large number of students contemplating dropping out of the course is a concern, as is the largely insignificant role of staff in persuading those students to stay.

While this study has provided some explanation of the high attrition of females in computing courses, the challenge still remains to develop strategies to minimize it.

KEY TERMS

Attrition Rate: A measure of the proportion of students who fail to complete a course of study.

Further Training: Post-compulsory education and training, excluding degree and higher-level programs delivered by higher education institutions, which provides people with occupational or work-related knowledge and skills.

Gender Bias: The tendency to give greater attention to one gender over the other, whereby such favoritism is based on prejudice, stereotyping, distortion, and irrational preference.

Participation Rate: The percentage of all students (commencing and continuing) in a particular course of study.

Retention Rate: A measure of the proportion of students who re-enroll in a subsequent year (of those who have not completed).

Transition: A period of significant adjustment, development, and change affecting all spheres of students' lives.

Underrepresentation: Participation of less than 40% (according to the higher education definition).

Gender Differences in Adolescents' Attitudes about IT Careers

Martha M. Bleeker
Mathematica Policy Research, USA

INTRODUCTION

Adolescents are the fastest growing segment of computer and Internet users, reporting heavier use than their parents (Lenhart, Madden & Hitlin, 2005). Though the popularity of technology continues to flourish and drive the American economy, recent studies suggest that the revolution may be leaving females behind at later ages (Cooper & Weaver, 2003; McDonald, 2004). Employment data from the United States (U.S.) Bureau of Labor Statistics show that the U.S. high-tech computer industry employs nearly 5 million workers, making it one of the nation's largest and most lucrative industries. Yet the number of women earning computer science degrees in the U.S. has plummeted over the past two decades, causing women to be vastly underrepresented in the information technology (IT) workforce (McDonald, 2004; National Science Foundation, 2004).

BACKGROUND

After high school, the majority of young women make academic choices that steer them away from IT careers (Stabiner, 2003). Early gender differences in computer attitudes may be a precursor for later academic choices. Guided by Eccles and colleagues' (1998) expectancy-value model of achievement motivation, this article provides an analysis of gender differences in adolescents' attitudes about IT careers. The expectancy-value model of achievement motivation suggests that adolescents' expectations for success and interests predict career plans. Findings from past empirical research in the domains of mathematics and science corroborate this model and suggest that individuals base their educational and career plans on expectations for success and value/interest (Eccles, Wigfield, & Schiefele, 1998).

Expectations for Success in IT Careers

Although female college freshmen have significantly closed the gender gap in computer use, there are still overwhelming gender differences in adolescents' expectations for success in the IT domain (Dickhauser & Stiensmeier-Pelster, 2002). The gender gap in computer-related ability beliefs first appears in the elementary school years and widens as students move through high school, into college and beyond. By the time adolescents graduate from high school, the gender gap in computer attitudes is striking, with males reporting more positive attitudes toward computer technology than females (Kirkpatrick & Cuban, 2000).

While the gender gap in computer confidence has always favored males, the gap among the 2000 college freshman class was actually the largest in the history of the University of California—Los Angeles' (UCLA) ongoing survey of students. First-year college women and men reported almost equal computer use, but female freshmen were only half as likely as men to rate their computer skills highly (Sax, Astin, Korn, & Mahoney, 2000). Females are also more likely to consider themselves "not the type to do well with computers," and less likely to say they "could handle a more difficult computer course" (Young, 2000). This gap in self-confidence may contribute to the fact that men are significantly more likely than women to pursue careers in computer programming.

Interest in IT Careers

In addition to expecting less success with computers, girls also report less favorable computer value and interest, especially during adolescence. Most studies report minimal gender gaps in computer attitudes during elementary school; however, by the time students graduate high school, the gender gap in computer attitudes is significantly larger, with males revealing more interest in technology, even when computer experience is controlled (Kadijevich, 2000; Kirkpatrick & Cuban, 2000). Male students are also more likely than female students to enroll in high school computer classes, perhaps indicating higher levels of interest for boys than girls (AAUW Educational Foundation, 1998; Bleeker, 2005).

As females reach adolescence, they often begin to attach their career interests to people-oriented social contexts and become most interested in jobs that will allow them to make a difference in society (Eccles et al., 1998; Margolis & Fisher, 2003). Not surprisingly, most young women who choose to major in computer science typically enter the field because of applied purposes, rather than a passion for programming or technology (Stabiner, 2003). Unfortunately, young girls often fail to see the high-tech industry as a key to helping others or making a contribution to society.

Moreover, many adolescents choose to pursue occupations other than those in technology because they are unable to relate their everyday interests in computers to IT careers (see Dryburgh, 2000). Lack of interest in pursuing computer science degrees may be related to stereotypical perceptions of computer scientists (McDonald, 2004). Even though some adolescents spend more than 16 hours each week in front of a computer (Bleeker, 2005), many express negative views about programming work and have a general aversion to the field of computer science. Computing careers are often perceived as involving little human contact, consisting mostly of keyboard work and lacking in creativity. These job characteristics seem to be especially unattractive to girls (Gilbert, 2002).

CURRENT STUDY

Much past research has failed to look closely at adolescents' perceptions of *different types* of careers within the broad field of IT. Based on past work (see Eccles et al., 1998) showing the importance of girls' valuing of "people-society job" characteristics, it seems likely that females may value certain IT careers (Web development, technology assistance) more than others (programming). Most past studies (e.g., Kadijevich, 2000), however, have asked adolescents to report attitudes only about computer science careers, or have simply asked adolescents to estimate how often they might use computers in their future careers. This article moves beyond these limitations and attains a more complete picture of adolescents' levels of interest and efficacy for IT careers. By assessing adolescents' attitudes about various IT careers rather than simply asking about computer science, this study investigates possible gender-based trends in attitudes within the broad IT workforce.

During the fall semester of 2004, 460 student participants (213 girls, 247 boys) were recruited from two public high schools (grades 9-12) in the northeastern U.S. At both high schools, an identical Web-based survey was administered to students during class time in a computer lab. The majority of students enrolled in the high schools were European-American and from middle- to lower-middle-class households (National Center for Education Statistics, 2004; U.S. Census Bureau, 2000).

Adolescent participants were asked to answer questions about seven different IT jobs, indicating their *expectations for success* and *level of interest* in the occupation. The list of seven jobs was created using the IT occupations listed on the U.S. Department of Labor's computer science Web page (Bureau of Labor Statistics, 2003; see Table 1). To help participants assess their beliefs about each occupation, a short description of each job was included, based on descriptions provided by the U.S. Department of Labor (Bureau of Labor Statistics, 2003). Items were answered using seven-point response scales, ranging from "not very" to "very." Thus, higher scores represent more interest and greater expectations for success with IT careers.

Table 1. List of IT careers (provided on student survey)

- Computer scientist
- Computer systems analyst
- Database administrator
- Webmaster
- Web developer/designer
- Computer support services
- Computer teacher

Expectations for Success in IT Careers

A one-way multivariate analysis of variance (MANOVA) was used to examine gender differences in participants' expectations for success (i.e., efficacy) for IT careers. In general, boys reported significantly higher levels of efficacy for IT careers than girls. These gender differences, however, varied depending on the specific career within the IT domain (see Table 2). Boys reported significantly higher levels of efficacy than girls for computer science, systems analyst, database administrator jobs, Web master, computer support services, and computer teacher careers. There were no significant differences with regard to expectations for success in Web development jobs.

Interest in IT Careers

A one-way MANOVA was also used to examine gender differences in participants' levels of interest in IT careers. In general, boys reported significantly higher levels of interest for IT careers than girls. These gender differences, however, varied depending on the specific career within the IT domain (see Table 3). Boys reported significantly higher levels of interest than girls for computer science, systems analyst, computer support services and database administrator jobs. There were no significant differences with regard to interest in Webmaster, Web development or computer teaching jobs.

FUTURE TRENDS

The goal of the current study was to examine adolescents' attitudes about various IT careers in order to develop a better understanding of the gender gap within the IT industry in the U.S. Guided by Eccles and colleagues' (1998) expectancy-value model of achievement motivation, analyses were used to examine gender differences in adolescents' expectations for success and interest in IT careers.

Regardless of gender, interest in the IT jobs included in the current study was very low. On a seven-point scale, with larger values indicating more interest, the average level of interest ranged from 1.64 (database administrator) to 3.09 (computer scientist). Clearly, the majority of adolescents in the current study were not particularly interested in obtaining careers in IT. As expected, boys generally reported higher levels of interest for IT careers than girls. These gender differences, however, varied, depending on the specific career. Boys reported significantly higher levels of interest than girls for computer science, systems analyst, computer support services and database administrator jobs, though there were no significant differences with regard to interest in Webmaster, Web development or computer teaching jobs. Despite their low levels of interest, the adolescents (particularly male participants) did indicate moderate expectations for success in these careers. Thus, even though students were not necessarily interested in entering IT careers, they did feel confident that they could carry out these jobs.

Boys reported higher expectations for success than girls for all of the careers, with the sole exception of Web development. Although this finding is not entirely surprising, given recent research suggesting that males have significantly higher levels of computer efficacy than females (Kirkpatrick & Cuban, 2000; Sax et al., 2000), it is striking that such uniform gender differences were found with respect to expectations for success in IT careers.

Based on the literature suggesting that females are most interested in computers when they can see the relations between computer technology and applied and/or social contexts (Gilbert, 2002; Stabiner, 2003), it was expected that girls would be more likely to indicate interest in pursuing the more "people- and society-oriented" computer jobs, such as computer support services, Web design and teaching. Although these trends were not entirely true in the current study, it does appear as though gender differences were smaller and non-significant with respect to Web design and computer teaching. Overall, girls were most interested in Web development, and reported slightly higher interest for computer teaching and Web development careers than boys. Thus, it seems possible that females may become more involved in the technology workforce within the next several years, as these "people- and society-oriented" types of occupations become more visible and open to young women.

Although these findings have the potential to add to the literature on adolescents' computer attitudes, there are numerous future opportunities for research in this area. For example, the current sample was composed predominately of white adolescents from middle-class families in the northeastern part of the U.S. Thus, the current results cannot be used to understand race or ethnic-based differences in computer attitudes and activities, nor can the results necessarily be generalized across adolescents. Because computer access often varies by race, ethnicity and socioeconomic status (McConnaughey & Lader, 1998), and because some ethnic minority groups (e.g., Latino/as, African-Americans) are underrepresented in the current IT workforce (National Science Foundation, 2004), future research should attempt to measure IT career interest and expectations for success among adolescents from more varied backgrounds.

In addition, this study only provides information regarding students' *attitudes* about seven computer careers; no data is available on the actual careers these adolescents will eventually enter. Although the examination of adolescents' reports of interest and expectations for success in various IT careers offers an important first step in explaining gender differences in the IT workforce, future research should attempt to follow adolescents and young adults as they enter the workplace. Research that follows young adults on their educational and occupational pathways has the potential to help researchers understand why some individuals may choose to leave careers in the IT workforce, for example, even if they indicated interest in the field during high school.

Finally, the questions used to assess computer career interest and expectations for success were general and not presented in the context of other areas of work, possibly affecting the way adolescents answered the items. For instance, the survey generally asked adolescents how interested they were in having a job in Web development, rather than asking them if they were interested in designing Web sites for a particular type of company or industry. It is possible that adolescents would have indicated higher levels of interest if the computer careers were presented in the context of specific areas of work, such as health care, education or business.

CONCLUSION

The current findings corroborate Eccles and colleagues' (1998) expectancy-value model of achievement motivation. It appears as though females have less interest and lower expectations for success in IT careers during adolescence, and probably see technology as less important to their educational and career plans in comparison to their male counterparts (Mayfield, 2001). Importantly, most researchers involved in computer research agree that the basis of such gender differences in computer attitudes is essentially cultural and not related to inner ability. Females may simply value computers less than males, beginning in childhood (Kadijevich, 2000), and these early gender differences in computer attitudes likely preface the persistent under-representation of women in IT professions.

Findings from the present study could have implications for how educators introduce concepts and computer-related educational activities in the classroom. For instance, the current findings suggest that young women are especially interested in careers that involve Web development. To increase the number of female students in computer courses, schools may want to offer more classes that deal specifically with Web design and Web development, and school counselors should encourage female students to enroll in these courses. Teachers who instruct such courses may want to emphasize creativity, as well as the "people- and society-oriented" applications of Web design, helping students to see connections between careers in IT and the types of career characteristics they value most. Hopefully, classroom-level changes such as these will help encourage more females to consider careers in IT.

NOTE

This study was conducted at The Pennsylvania State University, in the Department of Human Development and Family Studies. Portions of this article were presented at the 2005 Women and IT Forum, Brisbane, Australia.

KEY TERMS

Computer Scientist: Individuals involved in this occupation work as theorists, researchers or inventors. They have high levels of theoretical expertise, solve complex problems and create new technology. They also develop and design specialized computer languages, programming tools, knowledge-based systems and computer games.

Computer Support Services: Individuals in this occupation deliver customer service and help others with computer needs and concerns. They possess strong interpersonal skills and a basic understanding of how computers operate.

Computer Systems Analyst: Individuals in this occupation solve computer problems and use computer technology to help businesses or organizations.

Computer Teacher: Individuals in this position teach computer and technology classes at an elementary school or high school and help students with computer needs and questions.

G

Database Administrator: People in this job set up computer databases, organize and store data and help people with their computer needs and questions.

Efficacy: An individual's belief about his or her capability to produce designated levels of performance.

Expectations for Success: Actual beliefs of students about their future performance on an upcoming task; expectations for success are positively related to achievement behaviors, such as choice and persistence.

Web Developer/Designer: People in this occupation are responsible for day-to-day Web site design and creation. Art or graphic design skills are desirable for Web developers.

Webmaster: These individuals are responsible for all technical aspects of a Web site, including performance issues, such as speed of access. They also approve and edit the material included on Web sites.

Gender Differences in Adoption and Use of a Healthcare IT Application

INTRODUCTION

Information technology (IT) adoption and diffusion is a central concern of information systems research and practice. The most widely-accepted method in IT adoption and diffusion research, the technology acceptance model (TAM; Davis 1989), posits that perceived ease of use and perceived usefulness are fundamental determinants of user acceptance. However, TAM and its subsequent research makes little or no reference to gender effects (Adams, Nelson, & Todd, 1992; Chin & Gopal, 1995; Venkatesh & Davis, 2000), despite the fact that researchers have shown that socio-cultural factors, such as gender and ethnic differences, influence human perceptions and behaviors (Hofstede, 1980). These socio-cultural factors can result in differences in user responses to technology innovations (Gefen & Straub, 1997).

Aiming to provide theoretical extensions to the TAM model, researchers have shown that gender differences may relate to beliefs and use of IT. For instance, males and females are found to demonstrate distinct adoption behavior in use of a wide spectrum of IT applications, such as e-mail (Gefen & Straub, 1997), mobile telephony (Ling, 2000) and Internet (Kraut, Scherlis, Mukhopadhyay, Manning, & Kiesler, 1996). Nevertheless, the exact gender effect remains a controversy. Some researchers believe that females are less technology inclined, less motivated and, therefore, less competent in masculine computer and technology culture (Wilder, Mackie, & Cooper, 1985; Qureshi & Hoppel, 1995). Others, in contrast, argue that females have the ability to be proficient in adopting new technologies (Turkle, 1995). Some research results indicate that females tend to favor some technology innovations and use them more effectively than males, such as computer-mediated communication (Kraut et al., 1996; Morahan-Martin & Schumacher, 1997).

In health care, influence of physician gender has long been noted in resident education and many practice areas. Researchers find the procedural and obstetrical care pattern of practice differs between male and female residents (Chaytors, Szafran, & Crutcher, 2001), and physician gender significantly affects treatments in adult primary care practice (Boulis & Long, 2004). An understanding of these socio-cultural issues is also of vital importance towards success of health care IT applications. This study is thereby designed to assess medical residents' acceptance and adoption of a Clinical Reminder System (CRS), by examining several key user characteristics that may relate to adoption and use of the system.

BACKGROUND

CRS is a class of computerized clinical decision support systems (CDSS) that send just-in-time alerts to clinicians when potential errors or deficiencies in patient management are detected. Beneficial outcomes of CDSS have been documented in many studies along a number of dimensions, including compliance with treatment standards, reduced costs and improved health outcomes (McDonald, Hui, Smith, Tierney, Cohen, Weinberger et al., 1995; Curtin, Hayes, Holland, & Katz, 1998). Several systematic reviews have also shown that CDSS can be an effective means of implementing medical guidelines to enhance clinical performance in wide-ranging aspects of medical care (Hunt, Haynes, Hanna, & Smith, 1998; Kaplan, 2001). However, most of these studies either focus on the accuracy and relevance of the computer-aided recommendations, or use experimental or randomized controlled clinical trials (RCCT) designs to assess system or clinical performance. Very few studies of CDSS involve a naturalistic design in routine settings with real patients (Kaplan, 2001). It is not clear whether a CDSS that has been shown to be effective in a laboratory setting will be fully utilized by end-users in clinical environments, and whether these users will adapt their practice style to efficiently accommodate computer-generated reminders.

Clinical users also differ in many ways. It has been recognized that individual users' experiences and their opinions or reactions to a technology make a difference in whether or not the technology will be adopted (Straub, Limayem, & Karahanna-Evaristo, 1995). Nevertheless, few studies have used individual-level data to measure the magnitude of user differentiation and the impact of such differentiation on technology adoption.

The present study aims to address some of these limitations. First, the system under evaluation, CRS, has been integrated into the daily operations of an ambulatory clinic. Second, longitudinal usage data for an evaluation period of 10 months were collected from computer logs, providing an objective and non-intrusive measure of the actual use over time. Third, a novel developmental trajectory method is applied to the usage data to identify groups that demonstrate distinct adoption behaviors, and to relate estimated group configurations to a variety of user characteristics.

The next section describes CRS and its basis in principles of evidence-based medicine. The study site and data collection procedures are then discussed, followed by a presentation of the trajectory analysis method for analyzing the usage data. The findings are presented next, and the final section presents some concluding remarks.

CRS AND EVIDENCE-BASED MEDICINE

Evidence-based medicine is the distillation of a large volume of medical research and standards into treatment protocols for diseases and preventive care procedures that represent the most accurate knowledge available (Sackett, Rosenberg, Muir Gray, Haynes, & Richardson, 1996). Evidence-based medicine has been widely applied to systematically review, appraise and use clinical research findings to aid the delivery and provisioning of optimum clinical care to patients.

The clinical decision support application that we developed, CRS, incorporates evidence-based medicine principles to assist in patient management decisions. It integrates the hospital's administrative, laboratory and clinical records systems into a single application, and uses patients' current medical status to provide reminders to clinicians at the point of care that reflect evidence-based medicine guidelines. Reminders generated by CRS take the form of recommendations to have tests scheduled and performed, receive vaccinations, alert clinicians to review abnormal test results or closely monitor patients with medical conditions that require unscheduled intervention. The CRS deployed at the time of this study is a distributed windows application based on client-server architecture. The clients are written in Visual Basic and communicate with an Oracle database server via the hospital's internal computer network. Evidence-based medicine guidelines are programmed in Oracle PL/SQL procedures.

STUDY SITE AND DATA COLLECTION

The study was conducted in the primary care clinic of an urban teaching hospital offering comprehensive health care services. Given the availability in every exam room of desktop computers installed with CRS, residents used the system during patient encounters.

Data collection started on February 1, 2002. In this study, we report 10 months of usage data to identify distinct user groups and maturation of their interaction with the reminder system. There were 44 active residents registered in the application. Activities generated by three of them are removed from the analysis since there were no visits recorded for these residents in 6 or more continuous months.

We have included in the study several key attributes of users that may relate to their human, contextual and cultural characteristics that in turn affect system use. These attributes are: general demographics including gender and citizenship (U.S. vs. non-U.S.); computer literacy identified by use, knowledge and optimism of computer systems; and frequency of encounters (work load). These attributes are found to influence adoption behavior in some other contexts (Berner & Maisiak, 1999). We have excluded a few other potentially influential attributes, because they are (a) invalid in the context, such as medical specialty (all users are internal medicine residents); or (b) lack of variation in the sample, such as age (mean 29.6, standard deviation 2.1); (c) sample size too small for defined subgroups, such as year of residency; or (d) inaccessible to us in recorded form, such as evaluation of residents' clinical performance (due to confidentiality concerns).

DEVELOPMENTAL TRAJECTORY ANALYSIS

We use a novel method, developmental trajectory analysis (DTA), to study user adoption behavior of this reminder system. DTA is a semi-parametric, group-based approach for identifying distinctive groups of individual trajectories within the population and for profiling the characteristics of group members (Nagin, 1999). It has provided valuable insights into studying physical aggression among youth (Nagin & Tremblay, 1999, 2001) and Web utilization and saturation patterns (Christ, Krishnan, Nagin, Kraut, & Guenther, 2001).

A "developmental trajectory" describes the course of a developmental behavior over age or time. DTA assumes that the population is composed of a mixture of distinct groups defined by their developmental trajectories. This method is useful for modeling unobserved heterogeneity in a population, where trajectories vary greatly across population subgroups both in terms of the level of behavior at the outset of the measurement period and in the rate of growth or decline over time. DTA also provides a multivariate procedure to examine impacts of individuals' characteristics on group membership probability, so the influence of the social-cultural factors, such as gender differences, can be evaluated.

RESULTS

The Trajectories

The developmental trajectories obtained from usage data are depicted in Figure 1. Bold and light lines denote observed and predicted trends, respectively. Observed data values are computed as the mean use rate of users assigned to each of these groups identified by estimation, and expected values are computed using DTA model coefficient estimates. We label these three groups as "Light" users, "Moderate" users and "Heavy" users, each comprising 17, 15 and 9 individuals (41.46%, 36.59% and 21.95%, respectively, of all users).

Figure 1 also reveals developmental trends of the adoption behavior. Users classified as "Light" initially utilized the system in about 35% of their encounters, and this rate remained steady over the 10-month study period. "Moderate" users had the highest initial use rate, about 70%, but this rate consistently decreased over the study period to a level comparable with that of the "Light" users. "Heavy" users had an initial use rate of approximately 50%, and this rate increased consistently to about 100% at the end of the study period. Changes in the use rate for members of the moderate group are of particular interest, since it indicates "Moderate" users demonstrated strong enthusiasm initially, while followed by a gradual decline in their use of the system.

Group Profiling

We now examine the association between adoption behavior and user characteristics to identify potential causal relations. Group profiles are shown in

G

Figure 1. Developmental trajectories of three distinct groups

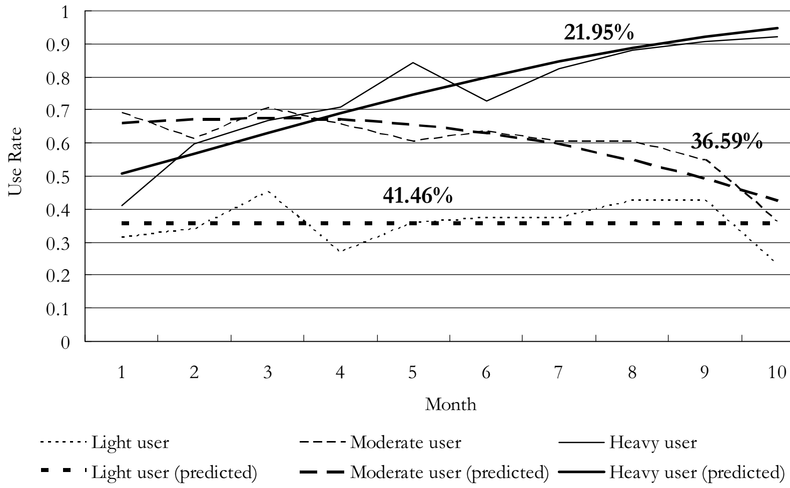

Table 1. Group profiles

User Characteristics	All	User Groups		
		Light	Moderate	Heavy
Female (%)	43.90	41.2	33.3	66.7
Male (%)	56.1	58.8	66.7	33.3
Non-U.S. citizen (%)	48.78	23.5	66.7	66.7
U.S. citizen (%)	51.22	76.5	33.3	33.3
Number of appointments *	14.04	14.13	14.12	13.75
Number of visits *	8.44	8.50	8.67	7.95
Number of visits w/ system use *	4.53	3.02	5.45	5.87
Computer use score	33.54	33.0	33.56	34.13
Computer knowledge score	32.96	36 **	31.33	31.38
Computer optimism score	53.19	48.56	52.78	58.88 ***

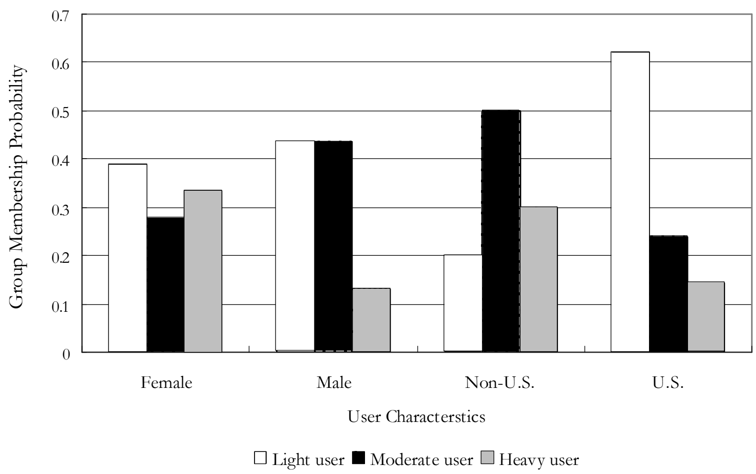
* Monthly average
** Significantly higher than that of the moderate user group at .05 level
*** Significantly higher than that of the light user group at .001 level

Table 1. For example, female users account for two-thirds of the heavy user group, whereas male residents account for two-thirds of the moderate user group. The lower portion of Table 1 shows real-scale measures. On average, each resident saw 8.44 patients each month during the study period (standard deviation 1.89); the maximum count of daily patient encounters is five, but this only occurred a few times. Since the frequency of patient encounters, monthly or daily, was low and relatively evenly distributed among residents, we do not deem this variable useful and will exclude it from further analysis.

The last three rows of Table 1 present the residents' computer literacy assessments obtained from Cork's instrument, measuring physicians' use of, knowledge about and attitudes toward computers (Cork, Detmer, & Freidman, 1998). These three items can be roughly interpreted as how often physicians currently use computers, how much they know about computers, and their relevant beliefs and attitudes. As indicated by Table 1, "Light" users have the highest computer knowledge score and "Heavy" users have the highest computer use and computer optimism scores.

Figure 2 shows the group membership probabilities for each of the categorical variables. For example, male users tend to cluster in the light and the moderate user groups, and non-U.S. citizens are more likely to be present in the moderate user group,

Figure 2. Mean group membership probabilities for gender and citizenship



whereas U.S. citizens are more likely to be present in the light user group.

Group profiles (see Table 2) are a collection of univariate contrasts. A multivariate procedure is provided in the DTA model to construct a more parsimonious list of predictors to sort out redundant variables as well as to control for potential confounds. Table 2 shows the impact of the covariates of interest on group membership probabilities. The upper panel shows coefficient estimates and t-statistics. We use the light user group as a *contrast group*. That is, for the light user group, the impacts of the covariates are set to zero, and the coefficient estimates for other groups are interpreted as measuring the impact of the covariates on group membership probabilities relative to that of the contrast group.

Table 2 shows the impact of gender on group membership probabilities. If a user is female, the probability of her being in the heavy user group is increased while the probability of her being in the moderate user group is decreased, compared to the probability of membership in the light user group. The lower panel of Table 2 shows the predicted membership probabilities based on multinomial logit model coefficient estimates. For each row, the impact of a single factor is evaluated. Being a female alone increases the probability of membership in the heavy user group. Similarly, having non-U.S. citizenship alone decreases the probability of member-

Table 2. The impact of user characteristics on the probability of assignment to usage groups

Variable condition	User Group		
	Light	Moderate	Heavy
Multinomial logit coefficients			
Gender – female	-	-.56 (-0.62)	.27 (0.24)
Non-U.S. citizen	-	1.67 (1.87)	.68 (0.6)
Computer use	-	.045 (.39)	.23 (1.46)
Computer knowledge	-	-.09 (-.985)	-.06 (-.546)
Computer optimism	-	.31 (2.18)	.98 (1.59)
Predicted membership probabilities based on multinomial logit model coefficient estimates			
Without user characteristics	.49	.36	.15
Gender – female only	.54	.27	.19
Gender – male only	.46	.41	.12
Non-U.S. citizen only	.29	.57	.14
U.S. citizen only	.63	.22	.15

ship in the light user group and increases the probability of being in the moderate user group. Impact of computer literacy also emerge: A higher score on previous computer use or computer optimism increases the probability of being in the heavy user group, and a higher score on computer optimism increases the probability of being in the moderate user group. In contrast, computer knowledge does not seem to affect usage significantly.

CONCLUSION

In this study, we assess 41 medical residents' acceptance and adoption of a clinical reminder system for chronic disease and preventive care management in an ambulatory care environment. We use a novel developmental trajectory approach to identify distinct groups, following distinct usage trajectories, among those who recorded use of the reminder system within an evaluation period of 10 months. We find that users in this study can be clustered into three groups: "Light" users, who used the system steadily over time for about 35% of their patient encounters; "Moderate" users, whose initial use rate was the highest (70%) among all groups but declined steadily to a level comparable with that of "Light" users; and "Heavy" users, whose use rate, initially moderate (50%), increased to nearly 100% at the end of the evaluation period.

We find that several user characteristics are correlated with usage levels and group membership probabilities. Females are more likely to be frequent users, while males demonstrate the other extreme. Female residents' tendency to comply with system use may be explained by social influence processes, such as subjective norm and their inclination to follow orders. Besides the gender influence, citizenship and attitude towards computers also play a role: Non-U.S. citizens are more likely to be frequency users than U.S. citizens, and computer optimism, rather than previous use and knowledge of computers, increases a user's probability of being a frequent user.

With awareness of such potential causal relations, researchers and practitioners can utilize user characteristics as a means of predicting future levels of usage and adoption. Gender-differentiated training programs and other just-in-time intensive strategies also can be developed and implemented to accomplish higher levels of technology acceptance and use and to minimize undesirable adoption behaviors.

KEY TERMS

Clinical Decision Support System (CDSS): A class of computer applications typically designed to integrate a medical knowledge base, patient data and an inference engine to generate case-specific advice. They intend to support clinical diagnosis and treatment plan processes and promote use of best practices, condition-specific guidelines and population-based management.

Clinical Reminder System (CRS): A computer system developed at Carnegie Mellon University and The West Penn Allegheny Health System. This system uses patients' medical history to provide just-in-time reminders to clinicians at the point of care that reflect evidence-based medical guidelines.

Developmental Trajectory Analysis: A semi-parametric, group-based approach for identifying distinctive groups of individual trajectories within the population and for profiling the characteristics of group members.

Evidence-Based Medicine: The distillation of a large volume of medical research and standards into treatment protocols for diseases and preventive care procedures that represent the most accurate knowledge available.

Health Informatics: A field of study concerned with the broad range of issues in the management and use of biomedical information, including medical computing and the study of the nature of medical information itself.

Information Technology Adoption: A micro process that focuses on the stages through which an individual passes when deciding to accept or reject the innovation of an information technology.

Medical Guideline: A document with the aim of guiding decisions and criteria in specific areas of health care, as defined by an authoritative examination of current evidence (evidence-based medicine). In the U.S., the National Guideline Clearinghouse publishes and maintains guidelines.

Random Control Trails (RCT): In RCT, study participants are assigned at random to either a control or treatment group to avoid bias and assure more objective results. People in the treatment group receive the new drug or are treated with the new device; the control group participants receive a more standard treatment, no treatment or a placebo (a look alike that has no active drug).

Technology Acceptance Model (TAM): An information systems theory that models how users come to accept and use a technology. The model suggests that when users are presented with a new software package, perceived usefulness and perceived ease-of-use are two primary factors that influence their decision about how and when they will use it.

Gender Differences in an Austrian IT Manufacturing Plant

INTRODUCTION

Despite the gains women have made in the last three decades, a large body of research has recently emerged suggesting that major economic changes occurring on a global scale are having detrimental consequences for women's labor-market position. At best, these developments are judged to likely limit further progress toward gender equality (Human Resources Development Canada [HRDC], 2002).

While in industrialized countries the manufacturing and primary industries have declined, the service sector, where women have traditionally been concentrated, has grown quite substantially. The service sector is highly heterogeneous, encompassing both well-paid professional and technical occupations as well as low-skill, poorly paid occupations. A stratum of highly skilled, high-status workers has emerged, coupled with a large mass of technically semiskilled or unskilled workers who acquire their training on the job or in short courses lasting a few weeks (Standing, 1989). Wage polarization has accompanied the growing demand for highly skilled workers and declining demand for unskilled labor. Increasingly, the workforce is segmented into a primary labor market offering good wages, job security, and opportunities for advancement, and a secondary labor market of low-paid, contingent workers (Economic Council of Canada [ECC], 1991). Women, and especially visible minority women, remain overrepresented in the latter.

Much of the literature on gender differences in the IT workforce has focused on the high-end IT jobs. Relatively little is known about low-end IT jobs and the role of gender. The IT industry is mainly a service-oriented industry. However, many of the tools used in these services have to be manufactured by IT manufacturers. In this study, we examine gender differences in the working conditions (job and organizational characteristics, and quality of working life [QWL]) of employees in a chip-manufacturing plant.

BACKGROUND

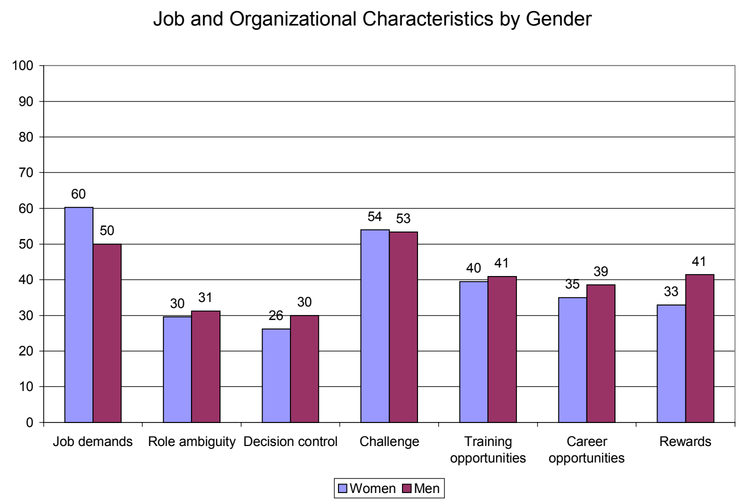
Services make up nearly two thirds of employment in the Western world. The role of other industries is becoming less and less important. Most of the manufacturing of goods is being outsourced to developing countries such as China, India, and so forth. However, at the same time, high-tech manufacturing has been developed in the Western world. The manufacturing of high-tech goods such as medical equipment and aerospace, aviation, and high-end IT products still partly takes place. Also, in the high-tech manufacturing industries of the industrialized countries, jobs are often held by technically semiskilled or unskilled workers who acquire their training on the job or in short courses lasting a few weeks (Standing, 1989). Furthermore, these jobs are characterized by nonstandard forms of work, such as part-time, temporary, and shift work. Women are much more likely than men to have nonstandard employment (Krahn, 1995). Working nonstandard hours typically puts people out of sync with family and friends, and may have negative consequences for the functioning of family life and the stability of marriages (Presser,

G

Table 1. Job positions by gender

	Blue Collar	White Collar	Total
Female	42 (93%)	3 (7%)	45 (7%)
Male	513 (86%)	80 (14%)	593 (93%)
Total	555 (87%)	83 (13%)	638 (100%)

Figure 1. Job and organizational characteristics by gender



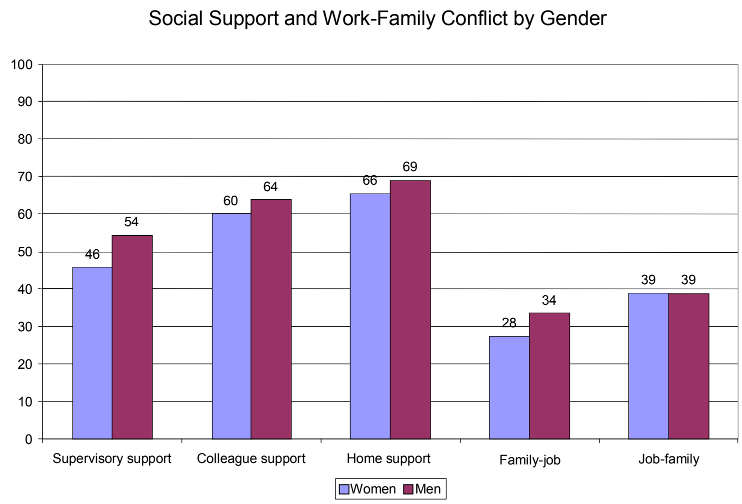
2003). Traditionally, women have been employed in the service sector. For example, the OECD (2005) reports that women are now overrepresented among public employees in all countries. In industrialized countries, 75% of women are employed in historically low-paying, service-sector jobs; 15 to 20% work in manufacturing; and some 5% in agriculture (International Labour Organization [ILO], 1995).

A large number of studies have dealt with gender differences in IT work. Earlier studies report that female IT workers have higher levels of psychosomatic complaints than male IT workers (Bradley, 1983). Furthermore, results have shown that monotonous and repetitive work with computers is more often performed by women (Evans, 1987), and women receive less skill upgrading by training than men (Gutek & Bikson, 1985). Therefore, quite a pessimistic picture of women and information-technology work emerges, putting an emphasis on the possibility that a polarization of qualification due to the technologies could be accompanied by a polarization between the sexes (Greve, 1987).

Some of the studies on job characteristics support this polarization hypothesis. In the study of Aronsson, Dallner, and Arborg (1994), the group of persons performing data-entry jobs—90% of whom were women—showed the highest level of psychosomatic complaints. On the other hand, programming personnel (mainly men) stated that due to the use of information technologies, their jobs had improved; they reported the lowest level of psychosomatic complaints. Further studies found more negative impacts of information technologies on work for women (Cressey, 1992; Hackett, Mirris, & Scales, 1991; Parasuraman & Igbaria, 1990).

While Austria has a general female employment rate clearly above the OECD average (in 2003, 61.5% of the women of working age were employed, as compared to an OECD total rate of 56.3% and an EU-15 rate of 56.1%; OECD, 2005), the female employment rate in the electrical and IT industries is relatively low. Especially low rates are found for blue-collar work, in which the female employment rate is 14.3%. In this article we compare the job and organizational characteristics, social support, work-family conflict, and quality of working life of male and female employees in an Austrian IT manufacturing plant.

Figure 2. Social support and work-family conflict by gender



MAIN THRUST OF THE ARTICLE

Data was collected at a chip-manufacturing plant in Austria. The questionnaire used was the German version of the American questionnaire used in the project *Paths to Retention and Turnover in the IT Workforce: Understanding the Relationships between Gender, Minority Status, Job and Organizational Factors* (http//cqpi2.engr.wisc.edu/itwf/index.html). For a full description of the questionnaire, see Carayon, Schoepke, Hoonakker, Haims, and Brunette (in press) and the other chapters by Carayon and Hoonakker in this encyclopedia. The German version of the questionnaire has been shown to be reliable and valid (Cronbach's alphas between 0.66 and 0.92). All scale scores in the questionnaire have been recoded to a score between 0 (lowest) and 100 (highest).

A total of 677 employees filled out the questionnaire (response rate was 74%). The female employment rate in the Austrian branch of the IT company is 13%. The majority of the sample (93%) is male. Thirty-eight percent of the sample is between 35 and 44 years old. The women in the sample are significantly older than the men: 57% of the men are older than 35 years, as compared to 81% of the women (Chi^2=13.6, $p<0.001$). Sixty percent of the men and 58% of the women in the sample have children.

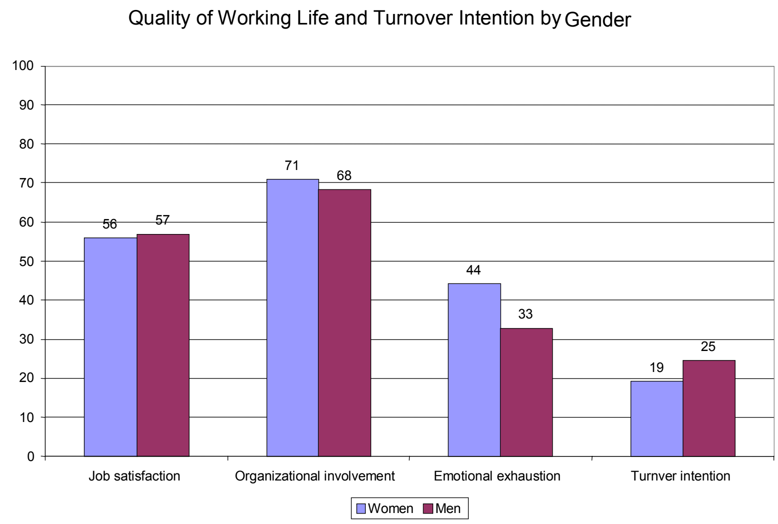
The average job tenure is 10.6 years, with slightly higher values for women (t=-6.03, $p<0.001$). As compared to the men in the sample, women have better education (14% men vs. 29% women have high-school education or better; Chi^2=8.21, p=0.02). Significantly more women have part-time jobs, although the percentages for both sexes are small (8% women vs. 1% men). If we exclude the women who work part time, both men and women work on an average 41 hours a week. There are no significant differences with regard to day-shift work: 84% of the women and 88% of the men work in alternate shifts. By law, only men are allowed to work in night shifts. There are no differences in self-reported income. Table 1 shows job positions by gender.

Eighty-seven percent of the sample holds a blue-collar job and 13% a white-collar job. The white-collar jobs consist mostly of supervisors. Although there are very few female white-collar employees, the gender differences are not statistically significant (Chi^2=1.72, p= 0.19).

Results show that there are few gender differences in job and organizational characteristics. However, the differences in psychological demands and rewards are statistically significant: Women perceive the job demands as higher than men ($p<0.001$), and men are more positive about the rewards than women ($p<0.01$).

Results show that the social support men receive is higher than the social support women receive. The differences in supervisory social support are statistically significant ($p<0.05$). Men complain more

Figure 3. Quality of working life and turnover intention by gender



about family-work spillover. However, these differences are not statistically significant.

Results show that there are some minor gender differences in quality of working life and turnover intention. Women report higher emotional exhaustion than men. The difference in emotional exhaustion between men and women is statistically significant ($p<0.01$).

FUTURE TRENDS

Due to major economic changes occurring on a global scale, recent research has shown that these changes may have detrimental consequences for women's labor-market positions, which may have a negative effect on gender equality. Historically, most women have been employed in the service sector and there are relatively few in manufacturing. Recently the service sector has undergone major changes. A stratum of highly skilled, high-status workers has formed, coupled with a large mass of technically semiskilled or unskilled workers who acquire their training on the job or in short courses lasting a few weeks. Increasingly, the workforce is segmented into a primary labor market offering good wages, job security, and opportunities for advancement, and a secondary labor market of low-paid, contingent workers, whose working conditions start to resemble the working conditions of manufacturing: nonstandard forms of work, such as part-time, temporary, and shift work. Women are much more likely than men to have nonstandard employment.

CONCLUSION

Although there are, as we expected, relatively few women in our sample of IT manufacturing workers, we were interested in gender differences in IT manufacturing for two reasons. First, although there is some literature about gender differences in the IT sector, there is relatively little known about IT manufacturing. Second, recently, within the service sector a secondary labor market of low-end jobs has been created whose characteristics have started resembling working conditions in the manufacturing industry.

Results show that there are relatively few gender differences with regard to job and organizational characteristics, QWL, and turnover intention in our study. However, women perceive higher job demands than men. They complain more often than men about the fact that their jobs often require them to work very fast ($p<0.01$), that there often is little time to get things done ($p<0.01$), that they often have problems to keep up with new technology ($p<0.01$), that they often have to stay at work because of customers' demands ($p<0.01$), and that they are more often overwhelmed by their workloads (p<0.001). Furthermore, they also report a higher rate of emotional exhaustion. They feel significantly more emotionally drained from their work (p<0.001), feel more often fatigued when they get up in the morning and have to face another day on the job (p<0.01), and feel more often that working all day is really a strain for them (p<0.001). However, they do not feel more frustrated by their job.

Men perceive better job resources, that is, more rewards and more social support. Therefore, the data may be seen as weak confirmation of the polarization hypothesis for the working conditions in this IT manufacturing plant in Austria. In similar job conditions, men seem to have better resources to deal with the job demands. Differences in the support scales indicate that increased work-nonwork role conflict may be the reason for the higher values in emotional exhaustion in women. If women and men do not share domestic responsibilities equally, then there is no wonder women are more exhausted at work!

KEY TERMS

IT Manufacturing: The sector that manufactures information-technology products, such as chips, computers, cell phones, networking devices, and so forth.

Job Satisfaction: Describes how content an individual is with his or her job. There are a variety of factors that can influence a person's level of job satisfaction. These factors include the level of pay and benefits, the perceived fairness of the promotion system within a company, the quality of the working conditions, leadership and social relationships, and the job itself (the variety of tasks involved, the interest and challenge the job generates, and the clarity of the job description or requirements).

Job Stress: Job stress is measured as burnout or the exhaustion of emotional and/or physical strength as a result of prolonged stress and/or frustration.

Organizational Involvement: The extent of an individual's involvement in an organization.

Quality of Working Life (QWL): Represents the quality of the relationship between employees and their total working environment, with human dimensions added to the usual technical and economic considerations.

Turnover Intention: The intention of an individual to move in or out of employment with a particular firm or organization.

Gender Differences in Defining Technology

Mari W. Buche
Michigan Technological University, USA

Our understanding of the computing profession strongly influences our approaches to education and research. (Peter Denning, 1991, p. 129)

INTRODUCTION

There is an alarming trend in the information technology (IT) career field: fewer women than in the past are entering the IT educational pipeline (Camp, 1997; Cukier, Shortt, & Devine, 2002; Whitaker, 2000; Woszczynski, Myers & Beise, 2004). Researchers have discovered a number of possible causes for this dearth including lack of female role models (Ahuja, 2002; Trauth, 2002), the "nerd" image (Braham, 1992; Menagh, 1998; Van Brussel, 1992), and family distractions (Ahuja, 2002; Trauth, 2002). With approximately 50% of the general workforce comprised of women in the United States, this statistic is alarming. At the same time, the IT skills shortage is rapidly becoming a global concern (Cukier et al., 2002; Trauth, 2002; Verton, 2004). The message is clear: something radical needs to be done now to attract and retain qualified, talented women to the IT field.

The general understanding of IT can be seen as an obstacle to attracting job candidates. When junior and senior high school students were asked about their perceptions of IT workers, the majority responded with terms like "weird", "nerd", and "geek (Menagh, 1998; Van Brussel, 1992). The derogatory tone is unmistakable since socialization practices of young girls influence their career choices long before they enter universities (Ahuja, 2002). The basic definition of IT learned through industry and government agencies invokes the areas of computer science and engineering (Cukier et al., 2002). The lack of a concise definition of IT precludes development of a deeper understanding of the problem (Woszczynski et al., 2004). In the past, technology workers have been required to possess strong mathematical and technical skills to create algorithms and to program in tedious computer languages (Weinberg, 1971). This practice ignores the multidimensional nature of IT work. Many workers enter the IT field through paths other than computer science or engineering education programs. So, why is the definition of IT so narrowly focused on these two areas?

The purpose of this article is to explore the influence of gender on perceptions of technology. Next, relevant literature from the information systems field is reviewed, followed by a comparison of definitions found in academic articles, textbooks, and practitioner journals. The next section describes the methods and results of a 2004 study on definitions of technology of undergraduate students (Buche, 2005). Themes extracted from their definitions are compared based on gender. Following the results, a first attempt at a gender-sensitive definition is proposed. The article ends with future trends and conclusions for managers and academics.

BACKGROUND

The role of IT professionals has been changing from that of a highly technical programmer (Weinberg, 1971) to a systems analyst, creating solutions to relevant business problems (Humphrey, 1997; Markus & Benjamin 1996, 1997). These job title changes signal continuous enhancement of responsibilities and tasks. The most obvious evolution is the increasing emphasis on problem solving, project management and communication, thereby bridging the gap between business end users and traditional software programmers. The skills required to be successful in these positions are broader than those found in computer science or engineering fields (Lee, Trauth, & Farwell, 1995). In spite of this realization, businesses continue to hire based on technical skill sets (Cukier et al., 2002).

Historically, feminist writings have addressed the definition of technology as being associated with male/masculine values. As Stewart Millar (1998) argues "[I]n contemporary western culture, men are assumed to make the machines, and, if culturally appropriate, women may use them." This argument is grounded in " ... traditional images of masculinity ... [representing] ... the technological 'Progress of Man' from so called barbarism to civilization ... " (p. 15). According to Stewart Millar "[s]uch an identification is reinforced by millennia of historically constituted gender constructions that have come to define our very notions of what it is to be male and female" (p. 15).[1] Technology has been defined and is often understood within this masculine social, cultural, political, and economic context (Wilson, 2004).

Denning divides the multiple areas of IT professionals into three general categories based on functions and expertise (2001, p.16). First, IT-specific disciplines include the highly technical specialties like artificial intelligence and computational science. The second group, IT-intensive disciplines, relies heavily on technology, but has a separate focus (e.g., financial services and telecommunications). The last set, IT-supportive disciplines, includes professional services that assist others in the use of technology (e.g., help desk technicians and system administrators). This conceptualization of technology includes more specialties with female workers (Woszczynski et al., 2004). The next section introduces a number of definitions of technology extracted from the IT literature.

Comparison of Definitions of Technology and Information Technology

A concise definition of the term technology is often absent from academic articles and textbooks in the IT field. Authors either assume that the term in self-explanatory, or they choose to allow the reader to define the term individually, according to background and personal expertise. A comparison between the definitions will reveal some of the socio-cultural forces that have helped to shape the IT field and perceptions of potential female IT professionals.

"Whenever we see the word *technology* or *technique*, we automatically think of machines" (Ellul, 1964, p. 3). Ellul divides the terms into two parts: technical operations and technical phenomenon. The technical operations contain the view of the process of creating innovation, while the technical phenomenon includes the products created.

Ferré (1988, p. 14) also acknowledges two aspects when defining technology. First, technology is the "*study* of practical arts or (by analogy with bio*logy* or anthropo*logy*) the *science* of the industrial arts." Secondly, technology "refers to the practical arts and products themselves." He discusses technology as both a science and the artifacts or tools produced by innovation.

Cukier, et al., state that "most of the work to date, even by feminists, has accepted the prevailing idea that 'information technology' is virtually synonymous with engineering and computer science" (2002, p. 8).

From current textbooks, information technology is "a term used to refer to a wide variety of items and abilities used in the creation, storage, and dispersal of data and information. Its three main components are computers, communications networks, and know-how," (Senn, 2004, p. 13). The tools definition is obvious in Laudon and Laudon (2004, p. 14) textbook: "Information technology is one of many tools managers use to cope with change." Jessup and Valacich (2003, p. 8) define technology as "any mechanical and/or electrical means to supplement, extend, or replace human, manual operations or devices", and "information technology refers to machine technology that is controlled by or uses information." This definition focuses almost entirely on computer-based solutions.

Although there are similarities between the definitions, the general consensus appears to support technology as existing in engineering and mathematical domains. The next section discusses a study that investigates the influence of gender in the way technology is defined.

METHOD

Over three semesters, the researcher collected definitions of the term "technology" from 197 undergraduate students participating in the core course Information Systems/Information Technology Management (Buche, 2005). The students were primarily business majors in a small, Midwestern university. The students had previously completed a basic

Table 1. Demographics from student respondents

Gender		
Female	54	27%
Male	143	73%

Table 2. Familiarity with technology by gender

Comfort Level	Females (n = 54)	Males (m = 143)
Novice	15 (28%)	18 (13%)
Intermediate	39 (72%)	82 (57%)
Expert	0	43 (30%)

computer skills course, so they had some foundational knowledge of the subject. During the first class period, each student was instructed to write out a definition for the term "technology" on a personal introduction card. Although no artificial incentive was offered for participation, most of the students provided a response. Time limits were not imposed, so students could write as much or as little as they deemed appropriate. Other requested information on the card was name, major/concentration, status (expected graduation), e-mail address, personal assessment of comfort level with technology (Novice/Beginner, Intermediate, or Expert), desired learning outcome of the course, and future career goals.

Since context can impose a strong bias, it is important to note that the university's overall focus is primarily engineering disciplines. The business school comprises slightly less than 10% of the total enrollment. Within this engineering culture, business students often pursue more technologically intensive curricula than many comparison universities. Additionally, many business school students originally entered the university as engineering or computer science majors. These factors undoubtedly contribute to the results discussed later in the chapter.

The demographic information was analyzed for descriptive statistics (Table 1). Using a content analysis approach, a number of common themes emerged from the data. A coding scheme was developed based on previous literature and amended to fit the data. The concepts were aggregated into categories based on logical classifications (Table 3). The results of the study follow.

RESULTS

There are a number of interesting findings from the analysis. As shown in Table 2, none of the females identified themselves as experts. This is consistent

Table 3. Coding schema for technology by gender

Code	Definition	Example from Data
TOOL	Identifies a product or device that is used to meet a specific need or improve communication	Technology is anything in this world that allows us to freely communicate.
