Editorial preface

The Social Science Encyclopedia aims to provide a broad, authoritative, accessible and up-to-date coverage of the social sciences in a convenient format. It is intended for a sophisticated but not necessarily specialist readership, including social scientists, students, journalists, managers, planners and administrators, and indeed all those with a serious interest in contemporary academic thinking about the individual in society.

Major entries survey the central disciplines in the social sciences, and there are substantial reviews of important specialisms. Theories and topics of special interest are covered in shorter entries, and there are also surveys and specialist entries on methods and in the philosophy of the social sciences. There are profiles of key historical figures, and on the schools of thought that have shaped the social sciences. Finally, the Encyclopedia deals with applications of the social sciences, in management and industrial relations, in economic and financial analysis and in planning, in communications and opinion polls, in therapy, in aptitude testing and the measurement of intelligence, in social work, in criminology and in penology.

The first edition of this Encyclopedia appeared in 1985, to a generous welcome, but a decade later it clearly required renewal. Many fields had moved on from the preoccupations of the 1980s. There were urgent new debates, influential books and popular courses on subjects that had barely appeared on the horizon when the first edition was published. Post-modernism had just begun to make an impact on the social sciences in the mid-1980s, feminism was still widely regarded as an embattled, radical fringe movement, sociobiology was associated with a simplistic genetic determinism, and Marxism was still a protean source of argument in a number of disciplines. Privatization and regulation and new versions of liberalism were not yet the burning topics of debate that they became in the following years. Communication, culture and media studies had already started to establish themselves, but they began to flourish only in the mid-1980s. The 1990s have seen the coming of age of new fields of enquiry, such as environmental, evolutionary and experimental economics, civil society and citizenship in political science, and connectionism in psychology; the revitalization of some cross-disciplinary projects, including cultural studies, cultural geography and cultural history, sociolegal studies, and economic and psychological anthropology; and the fresh influence of new or revived ideas, including rational choice theory, game theory, neo-Darwinism and reflexivity.

Clearly, then, a new edition was required. Indeed, the Encyclopedia had to be radically recast. The new edition is a similar size to the original, and the format has been retained, but nearly 50 per cent of the approximately 600 entries are new or have been completely rewritten; a further 40 per cent have been substantially revised; and only about 10 per cent have been retained in their original form.

Introducing the first edition we noted that the various social science disciplines clearly form a single arena of discourse, comparable debates cropping up in a variety of fields,

new ideas crossing easily from one discipline to another. As editors, we have often found it difficult to decide whether the author of a particular entry should be a psychologist or an anthropologist, an economist or a sociologist, a demographer or a geographer, a political scientist or a historian. Is rational choice theory the primary concern of political scientists, economists or sociologists? Are the notions of the body and the self especially salient to the current interests of psychologists or sociologists, or would it be more interesting to tap the debates of anthropologists or historians? On reflexity, rationality and rationalism, or relativism, should the floor be given to philosophers, sociologists, or anthropologists? Is the welfare state better explained by a political scientist, a historian or a social worker? In the event, these problems proved to be less difficult to resolve than might be imagined. We found that the choices we made did not necessarily make a great deal of difference, since a great many central ideas and arguments cross-cut the disciplines.

To a considerable extent this Encyclopedia necessarily illustrates the extent of interconnectedness, of overlap, if not of cohesion among the intellectual traditions which comprise the social sciences. This is not to deny the diversity of theoretical perspectives. However, a single field of discourse does not necessarily require a shared paradigm. Through interchange, by a process of challenge and response, shared standards and concerns develop. The attentive reader will find that certain themes recur, cropping up in the most unexpected places, and that an initial enquiry may lead from an obvious startingpoint right across disciplinary boundaries to perhaps hitherto unheard of destinations.

Another aspect of this unity in diversity appears from the fact that although the bulk of our 500-odd contributors are drawn—in almost equal numbers—from the USA and Britain, there are a substantial number of contributions from other western European countries and also from Australia, Canada, India, Israel, Japan and South Africa. The fluidity of disciplinary boundaries is matched by the international character of the modern social sciences.

But we should not exaggerate the convergences, or the areas in which a certain degree of consensus reigns. There is certainly more than enough diversity to raise questions about emphasis, or even bias. We have selected our contributors for their individual expertise, but inevitably they represent a very broad cross-section of opinion and a variety of intellectual orientations: indeed, that is surely one of the strengths of this volume. The balance comes from reading further, following up cross-references, so that one perspective is balanced by another.

It is, of course, precisely this sort of diversity that has led some to query the scientific status of the social sciences (though social scientists have raised interesting questions about what constitutes a proper science). Desirable or not, the divergences are real enough. The new edition of the Encyclopedia accordingly reflects the controversies as well as the common assumptions. Our ambition remains to review the whole gamut of ideas on the individual and society that have emerged from a century of academic research, criticism and discussion.

A

accelerator principle

In contrast to the (Keynesian) multiplier, which relates output to changes in investment, the accelerator models investment as determined by changes in output. As the principle that investment responds to the changes in output which imply pressure on capacity, the accelerator has a long history, but its formal development dates from the realization that its combination with the multiplier could produce neat models of cyclical behaviour. J.M.Clark originally noted the possibilities inherent in such models, but their first formal development was by Lundberg (1937) and Harrod (1936), and subsequently by Samuelson (1939a; 1939b) with Hicks (1949; 1950) and Goodwin (1948) and others providing refinements.

Suppose the optimal capital stock stands in fixed proportion to output, that is, formally:

$$K^* = \alpha Y$$

where

K^* is the desired stock of fixed capital
Y is annual output
α is the average and marginal ratio of optimal capital to output, i.e. $(K^*/Y = \Delta K^*/Y)$

Now let the subscripts t and t−1 refer to the variables in years t and t−1

$$K^*_{t-1} = \alpha Y_{t-1}$$
$$K^*_{t} = \alpha Y_{t}$$
so $K^*_{t} - K^*_{t-1} = \alpha(Y_{t} - Y_{t-1})$

Assume that the optimal capital stock was achieved in year t−l,

$$K_{t-1} = K^*_{t-1}$$

therefore

$$K*_t - K_{t\,1} = \alpha(Y_t - Y_t$$

To understand investment, that is, the flow of expenditure on capital goods, it is necessary to know how quickly investors intend to close any gap between the actual and optimal capital stocks. Let λ be an adjustment coefficient which represents the extent to which the gap between the realized and the desired capital stocks is to be closed.

Then

$$I_t = \lambda\alpha(Y_t - Y_{t\,1})$$
$$\text{or } I_t = V(Y_t - Y_{t\,1})$$

The λ and α coefficients together link investment to first differences in output levels and are described as the accelerator coefficient, here V Even at this elementary level the accelerator has several interesting implications. First, net investment determined by the accelerator will be positive (negative and zero respectively) if and only if $(Y_t - Y]_{t\,1})$ is positive (negative and zero respectively). Second, such net investment will fall if the *rate* at which output is increasing declines.

However, even at this simple level the weaknesses of the approach are also apparent. First, the results above relate *only* to investment determined by the accelerator, that is motivated as described above by a desire to expand capacity in line with output. It may well be that while entrepreneurs are influenced by relative pressure on their capital stocks, other factors also act as an inducement/disincentive to investment such as expectations, availability of new technology, and so on. Thus, the accelerator describes only a part of investment which might not stand in any fixed relation to total investment. Furthermore, the capacity argument really only models the *optimal capital stock*. To make the jump to the flow of investment requires the introduction of the λ coefficient which can be justified only by *ad-hoc* references to supply conditions in the investment goods industries and/or the state of expectations. In the absence of such additional assumptions it would only be possible to say that $I \gtrless O$ according to whether $K^*_t \gtrless K_{t\,1}$.

As suggested above, the accelerator has been fruitfully combined with the multiplier in models designed to explicate economic dynamics. Here the problem has been that while such models are useful in understanding the origins of cyclical fluctuation, realistic estimates of V predict an unreasonable degree of dynamic instability. This problem has generally been solved by combining the accelerator with other determinants of investment in more general models, and more specifically by theorizing the existence of 'floors' and 'ceilings' to income fluctuation, hence constraining potentially explosive accelerator multiplier interactions. In addition, generalized accelerator models themselves have provided the basis for empirical investigation of investment behaviour.

accounting

Accounting deals with the provision of information about the economic activities of various accounting entities, the largest of which is the whole economy, for which national accounts are prepared. However, the traditional province of the accountant is the smaller unit, typically a business firm. Here, a distinction is often made between financial accounting and management accounting.

F*inancial accounting* deals with the provision of information to providers of finance (shareholders and creditors) and other interested parties who do not participate in the management of the firm (such as trade unions and consumer groups). This usually takes the form of a balance sheet (a statement of assets and claims thereon at a point in time), and a profit and loss account (a statement of revenue, expenses and profit over a period of time), supplemented by various other statements and notes. The form of financial accounting by companies is, in most countries, laid down by statute, and the contents are usually checked and certified independently by auditors. In some countries, there are also accounting standards laid down by the accounting profession or by the independent bodies which it supports, such as the United States Financial Accounting Standards Board, which determine the form and content of financial accounts. The auditing and regulation of financial accounts is a natural response to the potential moral hazard problem arising from the information asymmetry which exists between managers and providers of finance. In the absence of such quality assurance, users of accounts would have little confidence in the honesty and accuracy of statements that could be distorted by management to represent its performance in the most favourable light.

M*anagement accounting* is concerned with the provision of information to management, to assist with planning, decision making and control within the business. Because planning and decision making are inevitably directed to the future, management

accounting often involves making future projections, usually called budgets. Important applications of this are capital budgeting, which deals with the appraisal of investments, and cash budgeting, which deals with the projection of future cash inflows and outflows and the consequent financial requirements of the entity. Management accounting is also concerned with controlling and appraising the outcome of past plans, for example, by analysing costs, and with assessing the economic performance of particular divisions or activities of the entity. Because the demand for management accounting information varies according to the activities, size and management structure of the entity, and because the supply of such information is not subject to statutory regulation or audit, there is a much greater variety both of techniques and of practice in management accounting than in financial accounting. Management has, of course, direct control over the information system of the business, so that formal regulation of the management accounting system is less important. However, within large organizations, there are information asymmetries and potential moral hazard problems between different groups (e.g. between branch managers and head office), and such organizations typically have internal auditing systems to reduce such problems.

Both management accounts and financial accounts derive from an accounting system which records the basic data relating to the transactions of the entity. The degree to which management accounting and financial accounting information can both derive from a common set of records depends on the circumstances of the individual accounting entity and, in particular, on the form of its management accounting. However, all accounting systems have a common root in double-entry bookkeeping, a self-balancing system, based on the principle that all assets of the entity ('debits') can be attributed to an owner (a claim on the entity by a creditor or the owners' 'equity' interest in the residual assets of the entity, both of which are 'credits'). This system owes its origin to Italian merchants of the fifteenth century, but it is still fundamental to accounting systems, although records are now often kept on computers, so that debits and credits take the form of different axes of a matrix, rather than different sides of the page in a handwritten ledger. The design of accounting systems to avoid fraud and error is an important aspect of the work of the accountant.

The traditional orientation of accounting was to record transactions at their historical cost, that is, in terms of the monetary units in which transactions took place. Thus, an asset would be recorded at the amount originally paid for it. Inflation and changing prices in recent years have called into question the relevance of historical cost, and inflation accounting has become an important subject. It has been proposed at various times and in different countries that accounts should show current values, that is, the specific current prices of individual assets, or that they should be adjusted by a general price level index to reflect the impact of inflation on the value of the monetary unit, or that a combination of both types of adjustment should be employed. Intervention by standard-setting bodies on this subject has been specifically directed at financial accounting, but it has been hoped that the change of method would also affect management accounting.

Financial accounting has also been affected, in recent years, by an increased public demand for information about business activities often supported by governments. Associated with this has been demand for information outside the scope of traditional profit-oriented accounts, resulting in research and experimentation in such areas as

human asset accounting, environmental (or 'green') accounting and corporate social reporting. There has also been more interest in accounting for public-sector activities and not-for-profit organizations. Recent developments in management accounting, facilitated by the increased use of computers, include the greater employment of the mathematical and statistical methods of operational research and greater power to simulate the outcomes of alternative decisions. This development has, however, been matched by a growing interest in behavioural aspects of accounting, for example, studies of the human response to budgets and other targets set by management accountants. The whole area of accounting is currently one of rapid change, both in research and in practice.

activation and arousal

The terms activation and arousal have often been used interchangeably to describe a continuum ranging from deep sleep or coma to extreme terror or excitement. This continuum has sometimes been thought of as referring to observed behaviour, but many psychologists have argued that arousal should be construed in physiological terms. Of particular importance in this connection is the ascending reticular activating system, which is located in the brain-stem and has an alerting effect on the brain.

Some question the usefulness of the theoretical constructs of activation and arousal. On the positive side, it makes some sense to claim that elevated arousal is involved in both motivational and emotional states. It appears that individual differences in personality are related to arousal levels, with introverts being characteristically more aroused than extroverts (H.J. Eysenck 1967). In addition, proponents of arousal theory have had some success in predicting performance effectiveness on the basis of arousal level. In general, performance is best when the prevailing level of arousal is neither very low nor very

high. Particularly important is the fact that there are sufficient similarities among the behavioural effects of factors such as intense noise, incentives and stimulant drugs to encourage the belief that they all affect some common arousal system.

On the negative side, the concepts of activation and of arousal are rather amorphous. Different physiological measures of arousal are often only weakly correlated with one another, and physiological, behavioural and self-report measures of arousal tend to produce conflicting evidence. Faced with these complexities, many theorists have suggested that there is more than one kind of arousal. For example, H.J. Eysenck (1967) proposed that the term arousal should be limited to cortical arousal, with the term activation being used to refer to emotional or autonomic arousal.

It may be desirable to go even further and identify three varieties of arousal. For example, a case can be made for distinguishing among behavioural, autonomic and cortical forms of arousal (Lacey 1967). Alternatively, Pribram and McGuinness (1975) argued for the existence of stimulus-produced arousal, activation or physiological readiness to respond, and effort in the sense of activity co-ordinating arousal and activation processes.

In sum, the basic notion that the behavioural effects of various emotional and motivational manipulations are determined at least in part by internal states of physiological arousal is plausible and in line with the evidence. However, the number and nature of the arousal dimensions that ought to be postulated remains controversial. In addition, there is growing suspicion that the effects of arousal on behaviour are usually rather modest and indirect. What appears to happen is that people respond to non-optimal levels of arousal (too low or too high) with various strategies and compensatory activities designed to minimize the adverse effects of the prevailing level of arousal (M.W.Eysenck 1982). Thus, the way in which performance is maintained at a reasonable level despite substantial variations in arousal needs further explanation.

adolescence

Definitions of adolescence typically indicate that it is the period during which those who have previously been encompassed within the category 'children' grow up. The very vagueness of when children can be said to have grown up is reflected in the lack of precision about when adolescence is supposed to occur. Most definitions indicate that it occurs between puberty and the attainment of physiological and/or psychological maturity. Both the onset (and end) of puberty and the attainment of maturity are extremely difficult to specify because it is possible to define them in a variety of ways and they occur at different times for different people. As a result, some writers concentrate more on adolescence as a hypothetically constructed period rather than as a precise age range. Those who do specify the adolescent years vary slightly in the ages they define, but generally indicate an extremely long period, from about 9 years to 25 years. The focus on puberty as crucial to the definition of adolescence has produced a concentration on biological, individualistic development rather than social development, although these areas are, in fact, inextricably linked.

The US psychologist Granville Stanley Hall is usually credited with the 'discovery' of adolescence in the late 1880s when he brought together a range of ideas which were current at the time. These ideas were similar to those described by Aristotle and Plato more than 2000 years ago and some of the themes identified by Hall have continued to generate interest. Hall borrowed the term *Sturm und Drang* (storm and stress) from German literature and applied it to the period of adolescence. This phrase is still often used, but rather imprecisely, to encompass both antisocial conduct and emotional turmoil, often also invoking psychological notions of an 'identity crisis' (borrowed from psychoanalytic theory) or a 'generation gap' between young people and their parents (Goleman and Hendry 1990).

Investigations of these phenomena (identity crisis and generation gap) indicate that a minority of adolescents do experience difficulties, but have not provided support for the belief that such difficulties are universal, or even widespread. However, twentieth-century concerns with (and moral panics about) political and social issues such as youth unemployment, juvenile delinquency, drug abuse and adolescent sexuality (both heterosexuality and homosexuality) have resulted in a profusion of publications on adolescence. More often than not, such publications take it for granted that adolescence is

problematic (Griffin 1993).

Writing on adolescence highlights epistemological contradictions between the study of adolescence and work in other areas. Following the work of the psychoanalyst Erik Erikson, it is often asserted that adolescence is a critical phase or period in the life course when identity has to be established in order for young people to become ready to assume adult sexuality and other adult responsibilities. However, this formulation runs counter to theoretical movements in developmental psychology which have shifted away from both age-stage thinking and from notions of critical periods. Furthermore, much of the outpouring of work on identity in adolescence has assumed that identities are coherent, unitary and hierarchically organized. Other work on identities or subjectivities from a range of disciplines has theorized it differently: as fragmented, potentially contradictory and multiple. This idea of fluidity and change in identities has become increasingly influential.

The problems of adolescence are generally assumed to be creations of late modernity. Yet historical analyses indicate that, far from being novel, many generations have considered that young people (and it is mostly young men who have been studied) are problematic (Cohen 1986). Those who refer to adolescence as a twentieth-century creation are generally referring to the fact that young people reach puberty earlier, stay in full-time education and hence remain dependent for longer than previous generations. There have also been suggestions that it is the absence, in western societies, of status markers signalling entry into adulthood that produces the interim state of adolescence.

The area of adolescence demonstrates commonalities and differences between psychology and other disciplines. Sociologists, for example, tend to refer to youth rather than to adolescence. However, the difference in terminology does not necessarily indicate different approaches to the age group. Some European traditions of sociological analysis of youth began with the psychological idea of adolescence as that phase of life in which individuals seek and formulate a self-concept and identity. The reason for this was the premise that the formation of subjectivity is significant for social integration and aspects of social change (Ghisholm *et al.* 1990).

Another joint adolescence/youth research tradition has been concerned with transitions to (un)employment. In psychology this has been particularly concerned with the psychological impact of youth unemployment, since, at least for young men, employment has long been considered one of the indicators of the attainment of independent adult status. In sociology, it has been largely macroanalytic and concerned with the ways in which school students experience school as well as how the educational system and pedagogic practices have an impact on social reproduction and social change.

A tradition which has been particularly influential was started at the Centre for Contemporary Cultural Studies in Britain. Their approach dominated youth research in the 1970s and early 1980s, gained influence in a range of countries and had an impact on subsequent research. Their orientation was a cultural studies one that challenged the tendency for adolescence to be discussed as if all young people pass through it at the same time and in the same way. Work in this tradition deconstructed notions that the category 'youth' is unitary and universal and argued that young people are differentiated by race and social class, but that, in themselves, young people also constitute a class fraction. A major part of youth studies within sociology came to be the study of youth

subcultures, usually male working-class subcultures, with a focus on leisure pursuits and style. Some have argued that the result of this was a trivializing of the whole 'youth question' to one of 'storm and dress' instead of the psychological 'storm and stress' (Cohen 1986). The lack of attention to young women in such work has also been much criticized (McRobbie 1991).

While there are similarities between the sociological study of youth and the psychological study of adolescence, there are also some notable differences. One important focus of sociology is the study of social divisions as a means to the understanding of structured systems of inequality along divisions of gender, race, social class and geography. The issue of the underclass and the polarization between relatively affluent and poor people has been consistently discussed since the late 1970s in sociology. Although the treatment of race and ethnicity in sociology has presented a rather two-dimensional picture of black and other minority young people, they continue to be absent within most of psychology, except when their racialized identities are being discussed. Social class and structural position have also been neglected within much of psychology although they are inextricably linked to definitions of adolescence and the ways in which young people spend their time. Gender among young people has not received a great deal of attention either in sociology or in psychology. However, it has also tended to receive rather different treatment in the two disciplines because sociologists have focused on young women's cultures while psychologists have tended to compare young women and young men.

The study of adolescence is thus a burgeoning field which, since it draws on a range of competing traditions from a number of disciplines, is far from unified.

advertising

Advertising, at its simplest, can be defined as the market communication of sellers of goods and services. Much of the early attention to advertising came from economists and was based around the key concept of *information* operating within a national market structure. A great deal of empirical research has been conducted on the effectiveness of advertising in raising product demand (both for individual campaigns as well as aggregate market consumption). The overall results have been inconclusive with regard to the economic effectiveness of advertising (Albion and Farris 1981).

Among the first theorists to develop alternatives to the concept of information were Marxist economists, who stressed instead its persuasive and manipulative functions. Advertising was viewed as a key component in the creation of demand, upon which capitalism increasingly came to rely as its productive capacity outstripped the provision of basic needs. In this view advertising is an indispensable institution to the very survival of the system, solving the growing difficulties of 'realization' in late capitalism (the transformation of value embedded in commodities into a money form) (Mandel 1978).

The location of advertising within this broader set of factors has prompted a great deal of historical work on the origins of the institution of advertising. Stuart Ewen (1976) pioneered this field, arguing that advertising fulfilled a key double function for capitalism at the turn of the century: both creating demand for the unleased industrial capacity of industry, as well as attempting to deflect attention away from class conflict at the workplace by redefining identity as being based around consumption rather than production. It was seen as a new and vital institution as capitalism transformed from its industrial to its consumer stage. Many other critical social theorists continue to see this as the most important function of advertising for capitalism. The cultural theorist Raymond Williams (1980) called advertising 'a magic system' that deflected attention away from the class nature of society by stressing consumption. In much of this literature advertising is seen as being the chief vehicle for the creation of *false needs.*

In this shift away from seeing the effects of advertising solely in economic terms, research space was opened up for a view of advertising that stressed its much broader and general effects. Leiss *et al.* (1990) argued for locating advertising within an institutional perspective (mediating the relations between business and media) in which the question of advertising's role in influencing sales was seen as much less important (and interesting) than its role as a vehicle of *social communication* (how it tried to sell goods by appealing to consumers along a whole range of dimensions not directly connected to

goods—individual, group and family identity; the sense of happiness and contentment; the uses of leisure; gender and sexual identity, etc.). Advertising here was described as an important part of the 'discourse through and about objects' that any society has to engage in. In this extension beyond a strictly economic orientation to a *cultural* perspective, the power of advertising was redefined also. Its influence was seen as being based on its ubiquitous presence in the everyday lives of people, stemming from its *privileged* position within the discursive structures of modern society. It is an institution that not only reflects broader cultural values but also plays a key role in redirecting and emphasizing some of these values over others. In this regard it was seen as performing a function similar to myth in older societies (Leymore 1975). Viewed from this perspective, advertising became seen as an important historical repository for shifting cultural values during the course of the twentieth century. Social historians (e.g. Marchand 1985) as well as anthropologists (e.g. McCracken 1988) used the data provided by this repository for their own broader historical and cross-cultural analysis.

Much of the recent (academic and social) concern with advertising is based on this view of it as a vital component of *popular culture.* The most sustained social science analysis of advertising has concerned the role it plays in *gender socialization.* Based largely on the methodology of content analysis, it has been conclusively shown that men and women are portrayed in very different types of social roles in advertising: women are represented in much narrower and subordinated ways (largely as sex objects or in domestic activities) than men (Courtney and Whipple 1983). There has been much speculation on the link between commercial images of gender and the subordination of women within society. The most advanced theoretical work on gender came from Erving Goffman (1979) who argued that the visual subordination of women was based on advertising presenting 'real-life' subordination in a 'hyper-ritualiziatic' form—again reflecting dominant cultural values as well as powerfully reinforcing them.

Another important area of concern around advertising is the effect that it has on *children's socialization* along a broad range of dimensions, especially health (in terms of nutrition) as well as the development of intellectual and imaginative capacities. In the most comprehensive analysis of its kind, Kline (1994) has argued that the marketing of children's toys has had a severe negative impact upon the kind of play that children engage in (limiting imagination and creativity), as well as inter-gender interaction and child-parent interaction.

Advertising is also connected with *health* concerns to do with the marketing of products such as alcohol, tobacco and pharmaceutical drugs. In particular, a great deal of attention has been paid to the relationship between tobacco advertising and tobacco addiction, with critics arguing that the nicotine industry uses advertising to maintain present markets by reassuring smokers about possible health concern, as well as drawing new users (largely children) into the market.

Increasingly, the techniques learned from product advertising have extended their reach into other areas of social life, such that more and more of the discourses of modern society are mediated through a commercial lens. Modern *political campaigns* are run the same as any other marketing campaign for a consumer good. Commentators have wondered about the impact this may have on the nature of democracy and the types of candidates that the process brings forth. Public health campaigns (e.g. for AIDS

education) are also using the techniques and the services developed first in the advertising industry (leading to the field labelled as social marketing).

There has also been much concern about the effect that global advertising will have on the cultural values of traditional societies hitherto outside the communication influence of the market, as well as the influence on media editorial content (entertainment and news) of income revenues that stem from advertisers (Collins 1993).

age organization

All societies share (up to a point) two components of age organization. These are age itself and the principles that govern seniority within each family, such as birth order and generational differences. In most pre-industrial societies, family position determines status, and age is a moderating factor only when there is an obvious discrepancy. In certain areas, however, and especially among males in East Africa, age is a major principle of social organization reckoned normally from the time at which groups of adolescents are initiated together into adulthood and share a bond that unites them for the remainder of their lives. Where ranking by age is controlled outside the family, this may inhibit competition between males that might otherwise be generated within the family. In other instances, anomalies between age and generational seniority may be critical and provide essential clues for exploring age organization in the wider social context; in extreme instances this should more accurately be described as a *generational system* rather than an *age system.* In other words, age organization has to be viewed as a

principle which may in some way structure the anomalies thrown up by the kinship system.

No age organization can be satisfactorily studied as an entity separated from its wider social context; for this reason many existing accounts of such systems which imply that they are self-contained and self-explanatory do not in fact explain very much, while those that seek to pursue the ramifications of the age system are inevitably daunting in their scope.

In the analysis of age organizations, the term *age-set* (sometimes age group, or *classe d'âge* in French) may be used to refer to all those who are initiated in youth during a definite span of time, and as a group share certain constraints and expectations for the remainder of their lives; and *age grade* (*échelon d'âge* in French) refers to a status through which all individuals pass at some period of their lives unless they die first. Each is an institutionalized arrangement governed by an explicit set of rules. The Nuer of the Southern Sudan have age-sets into which boys are initiated, but beyond this point they have no age grades. In our own society, we have age grades relating to infancy, schooling, adulthood and retirement, but (schools apart) we have no age-sets; members pass through these successive grades of their lives as individuals, and alone. In the more formalized instances of age organization, both institutions exist, and members of an age-set pass together through the various age grades, rather like pupils in a school. Using a ladder as an analogy for the system of age stratification, each rung *(échelon)* would represent an age grade, and successive age-sets would pass up it in procession, with youths climbing on to the lowest rung on initiation.

This procession involves a regulated cycle of promotions with a new age-set formed on the lowest rung once every cycle. The example of our own school system, stratified by year and with mass promotions once a year, is extremely rudimentary and consciously contrived to fulfil a task. In age organizations that span the entire lives of adults, the procession is more complex and the precise span of the periodic cycle is less predictable. A constantly changing configuration of roles occurs as members of each age-set mature and step up the ladder. Spacing tends to be uneven, with a certain jostling between successive age-sets at one point and sometimes a vacant rung elsewhere—an intermediate age grade with no incumbent. Changes in this configuration are predictable, however, and one complete cycle later there will be jostling and unoccupied rungs at precisely the same levels on the ladder, although each age-set meanwhile will have climbed to the position previously held by its predecessor. The anthropologist who normally only sees the system during one phase of the cycle, which may span fifteen years or more in some societies, has to use indirect evidence to piece together the profile of a complete cycle, but the existence of such regularities—the predictability of each successive phase—clearly indicates that this is indeed a system with its own inner logic and feedback mechanisms.

It is probably significant that formalized age systems are especially widespread in Africa, where there is a pronounced respect for older men in the more traditional areas and generally a higher polygyny rate than in any other part of the world. The older men are the polygynists, and the younger men correspondingly often face a prolonged bachelorhood. The existence of an age organization tends to structure the balance of power among men between the young who have reached physical maturity, and the old whose experience and widespread influence remain their principal assets despite failing

strength and falling numbers. This may be regarded as a balance between nature and culture, and is reflected in much of the symbolism associated with age organization which often emphasizes the depravity of youth and the respect due to old age, and imposes circumcision as a major step in the civilizing process administered by older men. It is they who control the rate at which younger men advance, when they can marry, and what privileges they can enjoy. Unlike the more widely reported opposition between males and females, a dynamic transformation constantly in play is between young and old, and the young have a long-term interest in the status quo which women can never enjoy in male-dominated societies. It is never a question of *if* they will take over from the older men, but when and in what manner. They have to assert themselves to show their mettle, and yet restrain themselves from any flagrant violation of the system that might undermine the gerontocratic system and damage their own reputation when they become older men. In nature, it is often males at their physical prime who control the females of the herd. In gerontocratic culture there is a displacement towards the men who are past their physical prime. They are the polygamists, while the younger men must wait as bachelors. The age organization, with its frequent emphasis on ritual and moral values, provides a system which the older men must control if they are to maintain their advantage.

age-sex structure

The age-sex structure of a population is its distribution by age and sex. The classification of the population according to age and sex can be given either in absolute numbers or in relative numbers, the latter being the ratio of the population in a given age-sex category to the total population of all ages by sex or for both sexes. The age distribution is given either in single years of age or in age groups, for example, five-year age groups. Broad age groups such as 0 to 14, 15 to 59, 60 and over are also sometimes used. The grouping of ages depends on the degree of precision desired, and on the quality of the data at hand.

If data are defective, as in some developing countries where people do not know their precise age, the classification by age groups is often to be preferred to the distribution by individual year of age, even if this implies a loss of information.

A graphic presentation of the age-sex structure of the population is the so-called *population pyramid.* This is a form of histogram, absolute or relative population figures being given on the axis of the abscissa, and age or age groups being represented on the ordinate. Male data are given on the left-hand side of the axis of ordinates and female data on the right-hand side. The areas of the rectangles of the histogram are taken to be proportional to the population numbers at each age or age group.
Figure 1 Population pyramid of Algeria (1966) (per thousand inhabitants)

Figure 1 presents, as an example, the population pyramid of Algeria in 1966. Population figures at each age are given here per 10,000 persons of all ages and of both sexes. One sees that the population of Algeria is young: the population under 15 years of age, for example, is quite large compared to the rest. One also sees that the classification by age in the Algerian census of 1966 is defective. People tend to round off the age they declare, yielding higher population numbers at ages ending by digits 0 and 5. In the Algerian case, this age-heaping effect is more pronounced for females than for males.

Another useful graph shows the differential distribution of sexes by age, presenting sex ratios by age or age group. Sex ratios are obtained by dividing the number of males in each age group by the corresponding number of females. The results are often called *masculinity ratios.* Masculinity ratios tend to decrease with age. At young ages there are

usually more boys than girls: approximately 105 male births occur per 100 female births. As age increases, masculinity ratios decline and become lower than 1, due to the prevalence of higher age-specific risks of dying for males than for females. On the whole, there are usually more females than males in the total population, due to excess male mortality. Masculinity ratios by age are also dependent on the impact of migration. If migration is sex-specific, masculinity ratios will reflect this phenomenon at the ages concerned.

One often speaks of young or old age structures. In the former case, the proportion of young in the population is high; the opposite is true in the second case. Young population age structures are essentially linked to high fertility. Ageing population structures are observed as fertility declines. The impact of mortality decline on age structure is much smaller than that of fertility decline, as the decrease in risks of dying affects all ages simultaneously. If decreases in risks of dying occur mainly at young ages, lower mortality will actually rejuvenate the population; the converse is true if gains in life expectancy are obtained principally at old ages.

If fertility and mortality remain constant over time and the population is closed to migration, a *stable* age structure will eventually result in the long run: the age distribution becomes invariant and depends solely on the age-specific fertility and mortality schedules. This property has been demonstrated by A.J.Lotka and is known as *strong ergodicity.*

ageing

The proportion of older adults in the populations of western countries continues to increase and is estimated to reach around 13 per cent by the end of the twentieth century. An understanding of the kinds of changes in cognitive processes and mental abilities that accompany normal ageing is important for many aspects of social policy, such as the appropriate age of retirement, the provision of housing suitable for older people and the need for support services.

The process of ageing is often confounded with other associated factors, such as deteriorating physical health, poor nutrition, bereavement, social isolation and depression, which also affect mental abilities so that it is difficult for researchers to

isolate and identify the effects of ageing. In addition, poor performance may be the product of sensory deficits, anxiety or lack of motivation rather than of mental deterioration.

Many mental abilities do show age-related deficits but others are unimpaired. In the words of Rabbitt (1993) it is quite wrong to suppose that 'it all goes together when it goes'. Different abilities show quite different rates and patterns of deterioration. Moreover, differences between individuals tend to increase in older populations. Most individuals begin to show some slight decline by the mid-sixties; with others problems begin earlier and are more severe; and about 10 per cent, the so-called 'super-old', preserve their faculties unimpaired into late old age. Traditional psychometric testing has yielded age norms for performance on batteries of standard intelligence tests. The results have led to a distinction between crystallized (or age invariant) intelligence and fluid (age sensitive) intelligence. Tests which measure intellectual attainments such as vocabulary, verbal ability and factual knowledge reflect crystallized intelligence and show relatively little effect of age. Tests measuring mental processes such as the speed and accuracy with which information can be manipulated as in backward digit span, digit-symbol substitution and reasoning, reflect fluid intelligence and generally reveal an age-related decline. Nevertheless, the pattern of decline within the category of fluid abilities is not uniform. The relationship between chronological age and performance on memory tasks is not necessarily the same as the relationship between age and speed of information processing. These complex patterns pose problems for theorists such as Salthouse (1992) who attribute age-related decline to the single global factor of 'general slowing'.

Experimental techniques reveal not only which tasks are impaired by ageing but also which of the component stages or processes are affected. For example, experimental studies of memory indicate that the retrieval stage is relatively more affected than encoding or storage and that short-term or 'working' memory is relatively more impaired than long-term memory. Semantic memory, which stores general knowledge, is stable, whereas episodic memory, which records events and experiences, is more likely to be defective. Age differences are most evident in demanding and unfamiliar tasks which require conscious effortful attention and the observed age difference tends to increase linearly with task complexity.

Since the mid-1980s many researchers have turned their attention to the systematic study of the effects of cognitive ageing on performance in everyday life. Using questionnaires, observations and naturalistic experiments which mimic real-life situations, the practical problems which commonly confront older adults have been identified (Cohen 1993) and, in some cases, remedial therapies have been devised. For example, older people tend to have particular difficulty in calling proper names; in remembering to carry out intended actions; and in remembering whether an action such as taking medicine has been performed or only thought about. Memory for the location of objects and for novel routes is unreliable. Memory for the details of texts and conversations is less efficient, and memory for the source of information (who said what) also tends to be poorly retained. Skills which require rapid processing of information from several sources such as driving also deteriorate markedly. Nevertheless, older people often develop effective compensatory strategies for coping with such problems, making more use of mnemonic devices, making adjustments in lifestyle and devoting

more effort and attention to selected activities.

Although the effects of cognitive ageing have been catalogued in considerable detail, much work remains to be done in developing a comprehensive theoretical framework and in mapping the cognitive changes on to the neurophysiological changs in the ageing brain.

aggression and anger

Biological/instinctual, psychoanalytic, ethological, social learning and cognitive theorists have all attempted to further our understanding of aggression, often spurred by a stated concern about humans' capacity to inflict suffering on others and by fears for the future of the species. While most would accept that some progress has been made, the actual achievements of social scientists to date are thought by some to be limited. The reasons for these limitations are of interest in themselves. Marsh and Campbell (1982) attribute lack of progress to a number of factors, including the difficulties in studying aggression, both in laboratory and naturalistic settings, and the compartmentalization of the academic

world, such that researchers fail to cross the boundaries dividing psychology from sociology, physiology and anthropology, or even the subdivisions within psychology itself.

There are, however, two even more basic problems which have inhibited progress. The first is the difficulty in arriving at any generally acceptable definition of aggression, and the second is the related problem of the over-inclusiveness of the theories themselves. An important starting-point in providing an adequate definition is to distinguish aggression from anger and hostility. Anger refers to a state of emotional arousal, typically with autonomic and facial accompaniments. A person may be angry without being behaviourally destructive and vice versa. Hostility refers to the cognitive/evaluative appraisal of other people and events. It would be possible to appraise a particular group in society in very negative terms without their eliciting anger or overt aggression, though in most cases cognition and affect will be intimately linked (see below).

Aggression itself refers to overt behaviour, though precisely what sort of behaviour should be labelled aggressive is controversial. Bandura (1973) proposes cutting through the 'semantic jungle' in this area by restricting the term to acts resulting in personal injury or destruction of property, while accepting that injury may be psychological as well as physical. There then remain problems in defining what is injurious and in dealing with 'accidental' aggression (where injury is inflicted but not intended) and 'failed' aggression (as when a person tries to shoot another person but misses). In general, the definition of an act as aggressive involves a social judgement on the part of the observer. For this reason, injurious acts may not be labelled as aggressive when socially prescribed (for example, capital punishment) or when they support values the observer endorses (for example, a parent beating a child to instil godfearing virtue). In this sense, labelling a behaviour as aggressive inevitably has a social and political dimension to it.

The second difficulty lies in the breadth of activities addressed by most theories. Stabbing another person in a fight, battering a baby, being abusive in a social encounter and waging warfare may all be behaviours that meet the definition of aggression, but they are also disparate activities with little obvious functional unity. This should, but often does not, preclude attempts to provide general theories which would account for them all. Many different theories are likely to be required to account for these different forms of aggressive behaviour.

In recent years the utility of one particular distinction has become apparent—that between 'angry' and 'instrumental' or what some have called 'annoyance-motivated' and 'incentive motivated' aggression (Zillman 1979). The former is preceded by affective arousal. The person is in an emotional, physiologically activated state, often induced by environmental frustration of some sort. In instrumental aggression, on the other hand, the aggressive act is used as a way of securing some environmental reward and emotional activation may not be present, as in the case of someone using violence to rob a bank. The two classes are not entirely independent in that environmental reinforcement is also involved in angry aggression, though the reward obtained is likely to be that of inflicting pain or injury itself.

The many sources of instrumental aggression have been well documented in psychological research. That some aggressive behaviour is indeed learned socially because it is effective in securing environmental rewards or because aggressive models for imitation exist is now widely accepted (for a review see Bandura 1973). The powerful effects of pressures towards obedience to authority in producing cruelty have also been shown in laboratory investigations. Recent years, however, have witnessed a renewal of interest in angry forms of aggression and it is on this work that I shall focus for the remainder of this article.

Angry aggression is an important feature of much of the violence which causes social concern. Studies of homicide, for example, suggest that the violent act is often a response to intense anger arousal. The violent person is often described as in a 'fury' or a 'rage', directed in many cases at a person with whom they have an intimate relationship (a wife or husband). Anger may also be involved in less obvious forms of violence. There is evidence, for example, that many rapes show features of angry aggression. A substantial number of rapists are in an angry/frustrated state preceding the assault and appear to be motivated to hurt and degrade the victim rather than to obtain sexual relief (Groth 1979).

Research on anger

Until the early 1980s, much less attention was directed by social scientists at the affect of anger than at its direct behavioural manifestations. Anger has been widely discussed by philosophers and poets but rarely by the experimental psychologist. The renewed interest in this phenomenological aspect of aggression stems in part from a general reconsideration of the emotions within psychology and also from developments in the field of cognition and its relationship to affect.

Anger seems to have four components—the environment, cognition, emotional/physiological arousal, and behaviour itself, and these components interact reciprocally in a complex fashion (Novaco 1978). The first two of these elements, in particular, have been the focus for experimental investigation. Anger and angry aggression are generally preceded by a triggering environmental event. There are a number of theories of what kind of event is likely to be important (the frustration-aggression theory, for example). Berkowitz (1982) argued persuasively that environmental events elicit aggression to the extent that they are *aversive.* Thus the absence of reward where it is expected or the blocking of goal-directed activity provoke aggression because they are unpleasant. Experiencing failure, being insulted, unjustly treated or attacked share the property of aversiveness and are capable, therefore, of producing anger and aggression. Berkowitz suggests that both humans and animals are born with a readiness to flee or to fight when confronted by an aversive stimulus. Which reaction will occur will depend on learning experiences (flight, for example, may have been found to be more effective) and on the nature of the particular situation (a situation where the person has expectations of control may make fight more likely). Consistent with Berkowitz's thesis that aversiveness is critical are a number of laboratory and naturalistic studies showing, for example, that pain is a potent elicitor of angry aggression. Unpleasant smells, 'disgusting' visual stimuli and high temperatures have

also been found to lower the threshold for aggression, though in the latter case the relationship is curvilinear.

Diary studies of what makes people angry in everyday life not only confirm the importance of aversive/frustrating events but also suggest a feature of anger not always apparent in laboratory studies—that it is predominantly elicited by *interpersonal* events. Other people, rather than things or impersonal occurrences, make us angry. James Averill (1982) found that people reported becoming mildly to moderately angry in the range of several times a day to several times a week and that only 6 per cent of incidents were elicited by a non-animate object. The frustrating person in over half the episodes was someone known and liked—friends and loved ones are common sources of aversive experiences.

The second component of anger is the cognitive processing of social and internal events. The concerns of cognitive theorists are typically with how people appraise, interpret and construct the social environment. Attribution theory has been a major force in cognitive theorizing, and attributional processes are now widely acknowledged to be relevant to angry aggression. Such processes are best viewed as mediating the emotional and behavioural responses to the aversive/frustrating events described above. The power of attributions can be appreciated by considering the differing emotional and behavioural consequences of various attributions for an event such as being knocked off one's bicycle on the way home from work. This painful and aversive occurrence might be attributed by the cyclist to personal inadequacies ('not looking where I was going') or to chance ('given the number of cars and bicycles it is inevitable some people are knocked down'). Neither of these attributions is, intuitively, likely to produce an aggressive response. Suppose, however, that the attribution was made that the car driver had deliberately intended to knock me off my bicycle. The threshold for aggression, at least towards the driver, might be expected to be considerably lowered by such an appraisal. Attributions of 'malevolent intent' of this sort have been shown to be important for anger and aggression (see Ferguson and Rule 1983).

The third and fourth components of anger are emotional/physiological arousal itself and the aggressive act which may or may not follow anger arousal. Anger is undoubtedly accompanied by autonomic activation (increases in blood pressure, heart rate, respiration and muscle tension and so on), but it is still unclear whether the pattern of activation can be discriminated from arousal caused by other emotions. Most experiences of anger in everyday life are not followed by physical aggression. Averill (1982) found that less than 10 per cent of angry episodes induced physical aggression. What he called 'contrary reactions', activities opposite to the instigation of anger, such as being very friendly to the instigator, were twice as frequent as physical aggression. Anger may produce a range of other reactions—the previous learning experiences of the individual are clearly important in determining whether frustration and anger are responded to with withdrawal, help-seeking, constructive problem-solving or what Bandura (1973) called 'self-anaesthetization through drugs and alcohol'.

The reciprocal bi-directional influence between the components of anger is something that has been stressed by Novaco (1978). Cognitions may induce anger and aggression, but behaving aggressively may activate hostile cognitions and also change the environment in such a way as to make the person even more frustrated. Hostile appraisals

of other people are often self-fulfilling. Untangling the complex interrelationships between these environmental, cognitive, physiological and behavioural component processes will be the major task for future aggression researchers.

agricultural economics

The first formal conceptualization of agriculture within economic theory can be attributed to the Physiocrats or, more specifically, to Quesnay's *Tableau Economique,* which modelled economic flows between different sectors on the eve of industrialization in France. Agriculture was held to be the only productive sector, since it allowed for extended reproduction in terms of grain, while the embryo manufacturing sector was seen merely to transform agricultural produce into other forms of artisanal or manufactured articles, and it was assumed that this latter process did not generate any additional economic value. A contrasting stance was adopted by English classical political economists. The key Ricardian argument was that the rising demand for food would extend the margin of cultivation to inferior lands and raise the price of grain as well as the rents accruing on all non-marginal land. Ricardo's pessimism about technological progress then led inexorably to the deduction that rent would erode the share of profit in the national product. Such a conceptualization of the economic process provided the theoretical underpinnings of the anti-landlord class bias of the classical economists. An exception was Malthus, who argued that agriculture was thus the generator not only of foodstuffs for the manufacturing sector, but also, crucially, of demand for its products.

From the common roots of classical political economy emerge two divergent systems of economic theorizing of agriculture: the Marxian and the neoclassical. The former focused special attention on the analysis of the role of agriculture in the transition from the feudal to the capitalist mode of production, a process characterized by primitive capital accumulation and surplus transfer from the pre-capitalist, mostly agrarian, sectors to the capitalist, mainly industrialist, ones. Both the classical and the Marxian approaches analyse the agricultural sector within a macroeconomic framework dealing, with the structural position and functional role of agriculture in terms of intersectoral and national economic linkages; both emphasize the importance of the generation and extraction of agricultural surplus—in the form of industrial crops, food and labour—for industrialization; both treat, though to different degrees, the dynamic intrarural dimensions of production relations and organization as necessary parts of the analysis. Thus, agriculture and industry are treated as distinct sectors, characterized by different internal technological and production conditions, social and political organization, and by different functional roles in the process of economic development.

The second offshoot of classical economy, neoclassical economics, now forms the disciplinary mainstream, and agricultural economics (as generally defined in the curricula of most universities) is identified closely with the method and schema of neoclassical theory. In sharp contrast to other traditions, neoclassical agricultural economics focuses primarily on microeconomic issues dealing with the static efficiency of resource use in agricultural production. The optimal choice of products, and combinations of inputs to produce these, form virtually its exclusive concerns. The central problem of agricultural economics is then reduced to one of profit maximization by an individual farmer operating with specified resources and technologies in an economic environment marked by perfect competition in all input and output markets. There is no analysis of the structure of agrarian production relations and organization or its transformation *vis-à-vis* the stimulus of economic growth. In general, production relations, for example, sharecropping, are analysed specifically from the vantage point of their impact through implicit (dis)incentive effects on the efficient allocation of available resources by decision makers. Within this framework, there has been a plethora of empirical studies which have asked the question: are peasants efficient in their resourceuse? The methodology has involved assuming perfect competition, and then deriving an econometric estimate—using cross-sectional data on a group of peasants—of a production function, frequently of the Cobb-Douglas type. A simple test for the equality of the estimated marginal productivity of each factor of production with respect to its relative price (with respect to the output) then reveals, within this paradigm, whether this decision maker could be adjudged to be efficient or not.

This framework was amplified initially in debates over sharecropping systems in the American South, but it has been advanced further in the contemporary context of rural development in the Third World. If one believes, as some celebrated neo-classical empirical studies argue, that peasants are poor but efficient, then additional agricultural growth is possible either if the relative price and hence the profitability of the agricultural sector is boosted, or if there is technological progress. The recipe is thus an improvement in agriculture's terms of trade alongside the use of improved methods such as those characterizing the so-called green revolution. While policies for rural education, health,

agricultural extension services and credit are justified as necessary for expediting rapid technological absorption, the prime emphasis is on the role of relative prices in guiding resource allocation. Another crucial corollary is that poor countries should not hesitate to concentrate resources on commercial crops and rely on heavy food imports so long as they enjoy a comparative trade advantage in the former at the going world prices. The validity of this policy package depends crucially on the realism of the fundamental premises underlying the neo-classical edifice. With regard to distribution, the twin assumptions of infinite factor substitution and perfectly competitive markets have been held to imply that growth would tend to increase the incomes of the landless labourers, leading to the contention that the benefits of agricultural growth would trickle down to the bottom echelons, even in highly inegalitarian property ownership structures. As such, neo-classical agricultural economics has provided the intellectual underpinnings for a conservative political programme.

Far from being perfectly competitive, however, agricultural product and factor markets are heavily segmented, interlocked and frequently governed by an unequal and personalized power equation between landed patrons and (near) landless clients; as such, peasants are frequently not independent decision makers. The production system has inherent externalities, for example, in soil conservation and irrigation, and uncertainties arising from information gaps and the elemental unpredictability of the delivery system and a changing technological matrix. A second criticism of the neo-classical approach applies to the behavioural postulates and the notion of efficiency. The economic calculus of rich farmers might be determined considerably by the longer-term objective of maximizing 'power' rather than short-term profits, while that of the poor is influenced by the immediate objective of guaranteeing survival in the face of price and output risks and uncertainty. The method ignores the realistic situation where the pursuit of efficient maximization algorithms of peasant profit-maximizers would lead dynamically to a process of collective deterioration, as in the widely observable illustrations of the vicious circle of ecological destruction. Neither is the question of the efficiency of the production relations themselves considered: alternative forms of production organization, *ceteris paribus,* could provide a powerful source of growth unrecognized by the paradigm of neo-classical agricultural economics. Finally, there are problems with the neo-classical modelling of agricultural production. For example, when the peasant farm is treated virtually as an industrial firm, the critical importance of the timing and interdependence of sequential cultivation operations is ignored. More significantly, the methodological validity of attempts to test for the economic efficiency of peasants through the use of a cross-sectional production function is highly dubious. The joint burden of these objections is to undermine the theoretical basis of the policy recommendations offered by the neoclassical approach.

Experience of Third World development in the postcolonial period has stimulated the discipline in several directions. Empirical studies have stimulated lively, theoretically eclectic debates, and resulted in the introduction of multidisciplinary approaches to the arena of conventional agricultural economics. Notable here are the resuscitation of Chayanov's theory of the demographic differentiation within the pre-1917 Russian peasant economy, Geertz's speculative interpretation of colonial rural Java, using the concept of agricultural involution, and Lipton's attribution of the persistence of rural

poverty to the phenomenon of urban bias. However, underlying this multifaceted diversity of agricultural economics are the latent roots of further disagreement and debate.

aid

The terms aid or development aid (often also foreign aid or development assistance) are not entirely unambiguous and are often used with slightly different meanings by different writers and organizations. However, there is agreement that in essence resource transfers from a more developed to a less developed country (or from a richer country to a poorer country) qualify for inclusion in 'aid' provided they meet three criteria:

1 The objective should be developmental or charitable rather than military.
2 The donor's objectives should be non-commercial.
3 The terms of the transfer should have a concessional element ('grant element').

Each of these criteria gives rise to some conceptual difficulty. The first one neglects the factor of 'fungibility', that is, that up to a point the use of resources by the recipient country is somewhat flexible. For example, aid may be given and ostensibly used for developmental purposes, but in fact the recipient country may use its own resources set free by this transaction in order to buy armaments; or the aid may lead to leakages and abuses and result in the building up of bank accounts in Switzerland, rather than to the ostensible developmental objectives.

   The second criterion, that the objective should be non-commercial, also presents difficulties. Much of the bilateral aid, that is, aid given by a single government to another government, is 'tied', which means that the proceeds must be spent on classified goods produced in the donor country. Here we clearly have a commercial objective mixed in with the developmental objective; it is again impossible to decide statistically at what point the transaction becomes a commercial transaction rather than aid. The line of division between export credits and tied aid of this kind is clearly a thin one. Moreover, many acts of commercial policy, such as reduction of tariffs or preferential tariff treatment given to developing countries under the internationally agreed GSP

(Generalized System of Preferences) can be more effective aid than many transactions listed as aid—yet they are excluded from the aid concept.

The third criterion—that the aid should be concessional and include a grant element—is also not easy to define. What, for example, is a full commercial rate of interest at which the transaction ceases to be aid? The grant element may also lie in the duration of any loan, in the granting of a 'grace period' (a time lag between the granting of the loan and the date at which the first repayment is due). The DAC (Development Assistance Committee of the OECD, the Organization for Economic Cooperation and Development in Paris) makes a valiant attempt to combine all these different aspects of concessionality in to one single calculation of the grant element. However, such calculations are subject to the objection that the grant element from the donor's point of view may differ from that from the recipient's point of view. In DAC aid in 1990/91, some 72 per cent was direct grants and the loans had a 59 per cent grant element, resulting in an 'overall grant element' for total aid of 85 per cent. The Development Assistance Committee is the main source of aid statistics, and its tabulations and definitions are generally recognized as authoritative. DAC publishes an Annual Report under the title *Development Cooperation;* the 1992 volume contained detailed tables and breakdowns of aid flows.

The OECD countries (the western industrial countries including Japan, Australia and New Zealand) and the international organization supported by them, such as the World Bank, the Regional Development Banks, the UN Development Programme, and so on, account for the bulk of global aid. DAC also provides some data on other aid flows such as from OPEC (Organization of Petroleum Exporting Countries) countries and from former USSR countries. Private investment, lending by commercial banks and private export credits are by definition treated as commercial and thus excluded from aid, although they compose a significant proportion of inflows into developing countries. Bank lending and export credits were exceptionally high by historical standards during the late 1970s and early 1980s. These levels proved unsustainable due to changes in the external environment and imprudent fiscal policy. The ensuing 'debt crisis' resulted in a sudden collapse of resource flows into developing countries. The total resource flow into developing countries in 1991 was $131 billion, of which $57 billion was ODA (Overseas Development Administration) from DAC countries (excluding forgiveness of non ODA debt), an average ODA/GNP ratio of 0.33 per cent (OECD 1992).

There is a growing concern over the unbalanced geographical mix of these flows. An increasing percentage of official development assistance is being directed to Sub-Saharan Africa, which has very low foreign direct investment, hence becoming increasingly aid dependent, which is not desirable in the long term. There is a broad consensus among donors and recipients that the aim of aid should be to assist in basic objectives of sustainable, participatory economic and social development. The role of aid is increasingly considered to be one of poverty alleviation rather than growth creation.

One of the main distinctions is between bilateral aid and multilateral aid (contributions of multilateral institutions such as the World Bank, the Regional Development Banks, and so forth). This distinction is also not entirely clear. For example, the western European countries give some of their aid through the EU (European Union). EU aid is not bilateral nor is it fully multilateral as the World Bank is; it is therefore to some extent a matter of arbitrary definition whether EU aid should be counted as bilateral or

multilateral. Multilateral aid is more valuable to the recipient than tied bilateral aid, because it gives a wider choice of options to obtain the imports financed by aid from the cheapest possible source. Untied bilateral aid would be equally valuable to the recipient; however, on political grounds, the recipient (and some donors, too) may prefer the multilateral route. Multilateral aid constitutes about 25 per cent of total aid.

It has been frequently pointed out that aid donors could increase the value of their aid to the recipients without any real cost to themselves, either by channelling it multilaterally or by mutually untying their aid by reciprocal agreement. However, this might lose bilateral aid some of the political support which it acquires by tying and which gives national producers and workers a vested interest in aid. This is particularly important in the case of food aid. Non-governmental organizations (NGOs), often in partnership with southern NGOs, are being increasingly recognized as holding an important role in aid distribution, particularly as a channel for official aid.

The 1980s saw a growing disenchantment with aid and consideration of the possibility that aid may even be damaging to the poor. Critics from the left have claimed that aid leads to the extension of international capitalism and supports the political motives of neocolonial powers (the high percentage of US aid flowing to Israel and Egypt is an example of aid fulfilling political interests). From the right, critics have claimed that aid supports the bureaucratic extension of the state, acting against the interest of free market forces and long-term development (e.g. Bauer 1984) and that developing countries have a limited capacity to absorb aid.

Aid appraisals at a micro level have generally concluded that aid had a positive impact. A World Bank study in 1986 estimated a rate of return of 14.6 per cent for its projects (White 1992). Cassen found that 'projects on average do produce satisfactory results in a very large proportion of cases' (Cassen 1986:307). However, some macroeconomic studies have failed to find a significant relationship between aid and growth. The macroeconomic role of aid can be modelled by a two gap model, shortages in capital creating savings and foreign exchange gaps, or bottlenecks, which can be bridged with foreign aid. However, whether or not aid does fulfil a positive macroeconomic role has not been empirically proven. Fears are often expressed that aid may be used to displace savings, particularly public sector savings. Additionally aid may have 'Dutch disease' effect, inflows of foreign aid increasing the price of non-tradable goods relative to tradables, hence creating the equivalent of a real exchange rate appreciation. This leads to a reduction in export competitiveness which may leave the country increasingly dependent upon aid.

Emergency relief is a part of ODA which is used in handling the consequences of an abnormal event which results in human suffering, including refugee assistance. Emergency aid is often considered as a separate category from a budget and planning perspective, although more effort is being made to link relief and long-term development assistance. In 1991 food aid comprised 6.1 per cent of total ODA aid by members of DAC (1993 Food Aid Review: 138), with a multilateral share of 23 per cent, similar to the multilateral share in financial aid. One-third of total food aid went to Sub-Saharan Africa, but Egypt and Bangladesh were the two largest recipients.

alcoholism and alcohol abuse

Alcohol use typically becomes a social problem with the emergence of industrialized, urban forms of social organization. Social disruption is more likely to accompany drinking in densely populated environments, and where person-machine interaction is central to work. In such contexts, alcohol use is causally linked to many disruptive behaviours: violence, low productivity and jeopardizing others through driving, boating or bicycling while intoxicated. While conclusive evidence that drinking causes these behaviours is rare, public opinion in North America tends not to question the destructive impacts of alcohol.

Social science involvement in alcohol studies began after the 1933 repeal of Prohibition in the USA. Social scientists promoted the conception of alcoholism as a disease rather than as a moral weakness (Bacon 1958; Jellinek 1960). This 'disease model' links chronic destructive drinking to biochemical mechanisms that are still unspecified.

The dependence of drinking outcomes on cultural norms is a key contribution of social science. Anthropologists have documented the widely variant outcomes associated with similar levels of alcohol consumption across cultures, notwithstanding the fact that its biochemical interactions with the human organism should be similar everywhere. Studies of ethnic differences in rates of drinking and alcoholism brought out the importance of

variant forms of socialization, social definition and social support (Marshall 1980).

There are, however, few widely adopted aetiological theories of alcohol abuse and alcoholism that are based in social science. While such theories exist (Akers 1977; Roman 1991; Trice 1966), their influence has been impeded by the premises underlying alcoholism intervention, especially Alcoholics Anonymous, and the treatment modalities that reflect its ideology. Furthermore, in most parts of the western world research funding flows toward medically linked science. Thus the alcoholism research establishment routinely presses for increased research allocations for work that adopts biological approaches.

Social scientists have been critical of the logic and internal consistency of the disease model of alcoholism (Fingarette 1988; Peele 1991). Their alternative proposals are unclear, however, especially as to how 'alcohol problems' should be treated differently from 'alcoholism'. What is called a new public health approach tends to muddle conceptions of deviant drinking, alcohol abuse, and alcohol dependence (Pittman 1991; Roman 1991).

A related body of research explores the consequences of different national and regional policies of alcohol distribution. These studies indicate that distribution policies influence the incidence of alcohol problems and alcoholism (Moore and Gerstein 1981). Given the heretofore myopic focus of alcohol research on North America and western Europe, a broader research base is vital as emerging nations struggle with radical changes in drinking norms accompanying both industrialization and the commercialization of alcohol distribution. Research by historians on all aspects of drinking and social policy is mushrooming and provides a critical background for cross-national considerations in the development of alcohol-related policies (Barrows and Room 1991).

While inconclusive, international comparisons have also put in question the view, common in Alcoholics Anonymous and in the treatment community, that abstinence is the only possible solution to alcohol abuse. A reduction of alcohol intake or a routinization of intake may also provide viable solutions (Heather and Robertson 1981). However, the diffusion of commercialized alcoholism treatment throughout the world tends to further the belief that the only cure is abstinence. This is fundamental to the medicalized model of alcoholism.

Social scientists are also involved in applied studies associated with alcohol problems. In the USA, Canada and Australia, social scientists have promoted the workplace as a setting within which persons with alcohol problems may be identified, confronted and rehabilitated without the costs of job loss and displacement (Sonnenstuhl and Trice 1990). In parallel fashion, social scientists have challenged the efficacy of educational strategies directed toward preventing alcohol problems among young people (Mauss *et al.* 1988).

In general, however, social science research on alcoholism is vastly overshadowed by the emphasis on biological aetiology and increasingly upon the potential of biomedical intervention. Fruitful social science research potential lies in understanding the dynamics of the various paradigms that ebb and flow across time and across nations, paradigms around which cultural conceptions of alcohol abuse and alcoholism are organized.

alienation

Alienation (in German *Entfremdung*), sometimes called estrangement, is a psychological, sociological or philosophical-anthropological category, largely derived from the writings of Hegel, Feuerbach and Marx.

In Hegel (1971 [1807]), we find the claim that the sphere of Spirit, at a certain stage in history, *splits up* into two regions: that of the 'actual world…of self-estrangement', and that of pure consciousness, which is, says Hegel, simply the 'other form' of that same estrangement. In this situation, self-consciousness is in absolute disintegration; personality is split in two. Here we have the *'entire estrangement'* of reality and thought from one another. This alienation will be overcome only when the division between Nature and Spirit is overcome—when Spirit becomes 'divested of self', that is, itself externalized.

This massive, objective, idealist philosophy of history was challenged by Feuerbach (1936[1841]) whose critique of Hegel centred precisely around a rejection of the latter's conception of the process of alienation. It is not that Feuerbach takes the 'separation' between subject and object to be a philosophical mythology. But this separation, he thinks, is assigned the status of a 'false alienation' in Hegel's work. For while man is real, God is an imaginary projection: 'the consciousness of God is the self-consciousness of man, the perception of God the self-perception of man'. Nor is nature a self-alienated form of the Absolute Spirit. But this reference to a 'false' alienation in Hegel suggests the existence of something like a 'true'—that is, really existing or operative—form of alienation. And Feuerbach does indeed believe in such a form; for it is only in some relation of contact with the objects which man produces—thus separating them off from himself—that he can become properly conscious of himself.

Marx (1975[1844]) seems to disagree. He argues that it is just by creating a world of objects through his practical activity that man proves himself as a conscious species-being. Under capitalism, however, the objects produced by human labour come to confront him as something *alien.* So the product of labour is transformed into an alien object 'exercising power over him', while the worker's activity becomes an alien activity. Marx adds that man's species-being then turns into a being alien to him, estranging him from his human aspect, and that man is thus estranged from man.

Marx's early writings, including the so-called *1844 Manuscripts,* were (re)discovered in the 1930s. Thus it was that some of their themes, including that of 'alienation', found their way into political, sociological and philosophical writings of the following period, including works of a non-Marxist character. A psychological line in alienation theory can also be identified, partially derived from Hegel (see below). The concept also, of course, has an ethical aspect: alienation is generally considered (whatever theory it derives from) a bad thing. It has even been said (Sargent 1972) to be 'a major or even the dominant condition of contemporary life'. An abundant literature exists on uses of the term (see Josephson and Josephson 1962).

Lukes (1967) has clearly identified the fundamental difference between two concepts which are apparently often confused: that of alienation, and that—introduced by Durkheim—of anomie. For Durkheim the problem of anomie man is that he needs (but misses) rules to live by, limits to his desires and to his thoughts. Marx's problem is rather the opposite: that of man in the grip of a system from which he cannot escape.

Althusser (1969 [1965]) developed a powerful critique of the notion of alienation as used by the young Marx, claiming that it was a metaphysical category abandoned by Marx in his later works.

It may finally be noted that the same term has appeared in the psychoanalytical writings of Lacan (197 7 [1966]), in the context of his theory of the 'mirror stage' in child development. This stage establishes an initial relation between the organism and its environment, but at the cost of a 'fragmentation' of the body. This may sound like a materialist version of Hegel's notion of the divided personality; and Lacan is indeed influenced by Hegel's analyses. It is, according to Lacan, in the relation between human subject and language that 'the most profound alienation of the subject in our scientific civilization' is to be found.

altruism

Parents sacrifice themselves for their children. Gift giving and sharing are universal. People help others in distress, give blood and may even donate a bodily organ to a stranger while still alive. In the Second World War some hid Jews from the Nazis at the risk of their own lives, and in 1981 IRA hunger strikers died voluntarily for their cause.

Theories of the origin of such altruistic acts, intended to benefit others at a cost to oneself, have come from both evolutionary and cultural sources. While Darwinian evolution is commonly equated with a competitive struggle for existence, theories developed since the 1960s have shown that altruism towards kin (Grafen 1991; Hamilton 1964), and reciprocal altruism (co-operation) between unrelated individuals (Axelrod 1984) are both favoured by natural selection under certain conditions. Kin-directed altruism is favoured because relatives have a high chance of carrying the genes predisposing the altruist to selfless behaviour. This means that if the altruist's loss of

fitness is outweighed by the relative's gain (devalued by the chance that the genes in question are carried by the relative), genes predisposing individuals to altruism will be favoured overall and spread through the population. The ubiquitous favouring of close kin is probably the result of such evolutionary forces.

The problem for the evolution of altruism between unrelated individuals is cheating, since those who receive without giving do best of all. When cheating can be punished, however, a game theory analysis shows that tit-for-tat reciprocation, that rewards altruism with altruism and punishes selfishness with selfishness, results in greater rewards than egoism (Axelrod 1984). When all individuals behave reciprocally in this way selfishness never arises.

This analysis fails to explain altruism between strangers, however, since it predicts reciprocation only when the same individuals interact frequently. Of more generality is a model in which self-sacrifice is culturally transmitted and benefits the social group. Here children adopt the commonest adult trait as their role model, such conformism itself being favoured by natural selection (Boyd and Richerson, in Hinde and Groebel 1991). This model fits well with the demonstrated tendency to favour individuals in one's own social group, and with ethnocentrism and xenophobia.

These models leave open the psychological issue of what motivates an individual to behave altruistically. This question has been central to the study of human nature since classical times, philosophers disagreeing over whether egoistic or altruistic impulses are at the root of human action, and consequently over the possibilities for ethical and political obligation. Under the hedonistic view all behaviour is motivated by the desire to avoid pain and secure pleasure, so that altruism is ultimately selfish. However, if all that is being claimed is that the achievement of goals is pleasurable, then hedonism indeed explains altruism but misses the interesting points that the goal in this case is to help another individual, and that some cost is suffered even though goal achievement might be enjoyed. There remains the difficult question of whether altruistic acts are performed to ameliorate the suffering of others or the saddened mood that normally accompanies empathy for a victim. Social psychologists who have disentangled these associated motivations have found conflicting results (Fultz and Cialdini, in Hinde and Groebel 1991), although empathic individuals do tend to show more helping behaviour. In addition, people may help even when they believe they would remain anonymous if they declined to do so, demonstrating that the good opinion of others is not a necessary motive for altruism.

In western societies altruistic tendencies are enhanced by the development in childhood of empathy, moral reasoning and the ability to take the perspective of others. These traits develop most readily in children whose parents are caring and supportive, set clear standards, enforce them without punishment, encourage responsibility and are themselves altruistic. These mechanisms may not be universal however; in the Utkuhikhalingmiut, an Eskimo group, for example, kindness is taught as a response to fear, reflecting its adult use as a means of defusing potential antagonism by feared individuals.

Norms of altruistic behaviour vary between cultures—western individualism contrasts with the collectivism of China and Japan, for example—and have their developmental roots in the way children are taught. Within small-scale egalitarian societies altruism may be valued more highly where there is little competition for resources or where a harsh environment favours co-operation.

anarchism

Anarchism is a political philosophy which holds that societies can and should exist without rulers. Anarchists believe that this will not, as is commonly supposed, lead to

chaos—anarchy in the popular sense—but on the contrary to an increase in social order. Anarchists see the state as the decisive source of corruption and disorder in the body politic. They point to many examples where people freely co-operate, without coercion, to achieve common purposes. Among traditional societies they find much to interest them in the 'ordered anarchies' of certain African tribes such as the Nuer, as well as in the workings of autonomous peasant communities such as the Russian *mir* and the self-governing cities of medieval Europe. In modern times they have hailed the anarchist experiments of the German Anabaptists of sixteenth-century Münster; the Diggers and Fifth Monarchists of the English Civil War; the popular clubs and societies of the French revolution; the Paris Commune of 1871; the Russian Soviets of 1905 and 1917; and the anarchist ventures in Catalonia and Andalusia during the Spanish Civil War.

Christ and Buddha have been claimed among earlier anarchists; and there were many social movements in both medieval Europe and medieval China which drew a fundamentally anarchist inspiration from Christianity and Buddhism. Religious anarchism continued into modern times with Tolstoy and Gandhi. But the modern phase of anarchism proper opens with the eighteenth-century Enlightenment, and can be traced equally from Rousseau's romanticism and William Godwin's rationalism. An early exponent was Godwin's son-in-law, the poet Shelley. Later advocates included the French socialist Proudhon, the German philosopher of egoism Max Stirner, the American individualist Thoreau, and the Russian aristocratic rebels Michael Bakunin and Peter Kropotkin. Anarchism was a strong current during the Russian revolution and its immediate aftermath; the suppression of the Kronstadt rising in 1921 and the emasculation of the Soviets signalled its defeat. But the ideas lived on, to surface not only in Spain in the 1930s, but also in Hungary in 1956, and in Paris in 1968, where the student radicals achieved a dazzling blend of anarchism and surrealism.

Anarchism has been incorporated into the political philosophy of a number of ecological groups, especially in Germany and the United States. It is strongly marked in such ecological utopias as Ursula Le Guin's *The Dispossessed* (1974) and Ernest Callenbach's *Ecotopia* (1975). These in turn have been influenced by earlier anarchist 'ecotopias' such as William Morris's *News from Nowhere* (1890) and Aldous Huxley's *Island* (1962).

Annales School

The journal *Annales d'histoire économique et sociale,* long planned, was founded in 1929 by two historians at the University of Strasbourg, Lucien Febvre and Marc Bloch, because they were unhappy with the manner in which history was studied in France and elsewhere, and wished to offer an alternative. They considered orthodox history to be too much concerned with events, too narrowly political, and too isolated from neighbouring disciplines. In their attempt to construct a 'total' history, as it came to be called (total in the sense of dealing with every human activity, not in that of trying to include every detail), Febvre and Bloch were concerned to enlist the collaboration of workers in the social sciences. They were both admirers of the work of Paul Vidal de la Blache in human geography, and interested in the ideas of Lucien Lévy-Bruhl on primitive mentality, while Bloch was also inspired by Durkheim's concern with the social and by his comparative method. The first editorial board of *Annales* included the geographer Albert Demangeon, the sociologist Maurice Halbwachs and the political scientist André Siegfried.

   The movement associated with the journal can be divided into three phases. In the first phase (to about 1945), it was small, radical and subversive. After the Second World War, however, the rebels took over the historical establishment. Febvre became president of the new interdisciplinary Ecole Pratique des Hautes Etudes. He continued to edit *Annales: Economies, Sociétés, Civilisations,* as it became in 1946, thus extending its range to the 'history of mentalities' practised by Febvre in his own work on the Reformation. He was aided by Fernand Braudel, whose doctoral thesis on *The Mediterranean and the Mediterranean World in the Age of Philip II* (1949) quickly made him famous. Braudel dominated the second generation of the movement, which was most truly a 'school' with distinctive concepts and methods. Braudel himself stressed the importance of the long term *(la tongue durée)* of historical geography, and of material culture *(civilisation matérielle)* Pierre Chaunu emphasized quantitative methods (l'histoire sérielle), notably in his vast study of trade between Spain and the New World, *Seville et l'Atlantique.* Pierre Goubert, a former student of Bloch's, integrated the new historical demography, developed by Louis Henry, into a historical community study of the Beauvais region. Robert Mandrou remained close to Febvre and the history of mentalities.

A third phase in the history of the movement opened in 1968 (a date which seems to mark the revenge of political events on the historians who neglected them). Braudel reacted to the political crisis by deciding to take a back seat and confiding the journal to younger men, notably Emmanuel Le Roy Ladurie. Le Roy Ladurie made his reputation with *The Peasants of Languedoc* (1966), a total history from the ground up in the Braudel manner, which used quantitative methods wherever possible, but he has since moved 'from the cellar to the attic', towards the history of mentalities and historical anthropology, as in his bestselling study of a fourteenth-century village, *Montaillou* (1975). The 1980s saw a fragmentation of the former school, which has in any case been so influential in France that it has lost its distinctiveness. It is now a 'school' only for its foreign admirers and its domestic critics, who continue to reproach it for underestimating the importance of political events. Some members of the *Annales* group, notably Le Roy Ladurie and Georges Duby, a medievalist, who has moved, like Ladurie, from rural history to the history of mentalities, are presently concerned to integrate both politics and events into their approach, and to provide narrative as well as analysis.

Others, notably Jacques Le Goff, Roger Chartier and Jean Claude Schmitt, have developed a new approach to the history of culture, in a wide sense of this term, including the history of rituals, gestures and ways of reading.

Since Braudel had a quasi-filial relationship with Febvre and a quasi-paternal relationship with Ladurie, the development of the *Annales* movement into a school and its fragmentation into a loosely organized group might be interpreted in terms of the succession of three generations. It also illustrates the cyclical process by which the rebels become the establishment and are in turn rebelled against. However, the journal and the people associated with it still offer the most sustained long-term example of fruitful interaction between historians and social sciences.

anthropology

The central issue in anthropology is human variation. In the nineteenth century the guiding idea was that there were significant biological differences between human

populations, and that these biological differences—notably in the development of the brain—explained variations in rationality, technical sophistication and social complexity. On one theory, each human 'race' had specific inherent capacities and therefore produced more or less sophisticated cultural forms and social institutions. The Darwinian discourse suggested, however, that there had been an evolutionary movement from more primitive to more advanced human types. On this view, there were still some primitive human populations, closer in every way to the primate ancestors of humanity. There were also relatively more advanced populations, who had progressed further from this common point of origin. This suggested that 'primitive' peoples—like, it was thought, the Fuegians, Australian aboriginals, and the South African Bushmen—were physically less evolved than other humans, lived in a 'primitive' society based on kinship and had a 'primitive' totemic religion. They were very like our own ancestors, who had lived many millennia ago. Dead civilizations revealed by archaeology and also many living populations represented intermediate stages of development between 'primitive' and 'civilized' peoples.

A major paradigm shift occurred in the first decades of the twentieth century, associated particularly with the father of American cultural anthropology, Franz Boas (1858–1942). Boas and his students were among the pioneering critics of racial theory, and they helped to establish that biological differences between extant human populations cross-cut the racial classifications; that these racial classifications were crude and unreliable, being based on a few phenotypical features; and that there were were no apparent differences in intellectual capacity between populations. It was not race that caused the differences between cultures. Cultural differences were themselves the main source of human variation. Anthropologists in the Boasian mould accordingly distinguished between biological and cultural processes.

Culture was conceived as that part of the human heritage that was passed on by learning rather than by biological inheritance. There were, however, two very different views of culture. E.B.Tylor and other evolutionist writers had typically treated culture or civilization as a single, cumulative attribute of humankind: some communities simply enjoyed more or less 'culture' as they advanced. The Boasian scholars were critical of these evolutionist speculations, and were more concerned with the differences between cultures. For them, culture was a distinct historical agency, the cause of variation between populations and the main determinant of consciousness, knowledge and understanding. In contradiction to the evolutionists, they insisted that cultural history did not follow any set course. A culture was formed by contacts, exchanges, population movements. Each culture was a historically and geographically specific accretion of traits. There was no necessary course of cultural development, and in consequence cultures could not be rated as more or less advanced.

If cultural and biological processes were largely independent of each other, the history of culture could be studied independently of the biological study of human evolution and variation. Although Boas himself contributed to 'physical anthropology' or 'biological anthropology', this became a distinct specialism in the USA. In Europe, physical anthropology (often confusingly termed 'anthropology') developed independently of what had initially been called ethnology, the study of peoples.

Some influential figures in American anthropology saw human evolution as the

organizing theme of anthropology and tried to preserve the 'four fields' approach, which linked cultural anthropology, physical anthropology, archaeology and linguistics, but increasingly the specialisms within anthropology diverged from each other. By the middle of the twentieth century the intellectual links between the four fields had become increasingly exiguous. Certainly there is some mutual influence. Archaeology has increasingly drawn on cultural and social theory, and under the influence of sociobiology some physical anthropologists have attempted to revive biological explanations for cultural behaviour. In general, however, cultural anthropology in North America and social anthropology and ethnology in Europe can be treated in isolation from the other anthropological disciplines. Cultural anthropology has been more influenced by developments in the study of language than by biology, and social anthropology has been particularly influenced by social theory and historiography.

Ethnographic research

Europeans had accumulated a considerable body of information on the peoples of Asia, the Americas and Africa since the sixteenth century, but the reports were often unsystematic and unreliable. Since the eighteenth century, scholars had increasingly concerned themselves with the study of the literary and religious traditions of the east. Reliable, detailed, descriptions of the peoples beyond the great centres of civilization were, however, hard to come by, and the universal historians of the Enlightenment had to rely on scattered and generally unsatisfactory sources. Even the pioneer anthropologists had to make do with decontextualized and often naïve reports of customs and practices, but in the last decades of the nineteenth century pioneering ethnographic expeditions were undertaken by professional scientists, typically surveys of extensive regions. Metropolitan anthropologists began to organize the systematic collection of ethnographic information. Their model was the field reports of botanists and zoologists, and the ethnographies they favoured typically took the form of lists of cultural traits and techniques, and often included physical measurements and data on natural history.

In the early twentieth century there was a shift to longer, more intensive field studies of particular cultures. Franz Boas made a long-term study of the native peoples of southern, coastal British Columbia, collecting a huge archive of vernacular texts from key informants. Russian scientists made intensive studies of the Siberian peoples, and European scholars began to publish studies of small societies in the tropical colonies. Between 1915 and 1918 Bronislaw Malinowski (1884–1942) engaged in a field study of the Trobriand Islands in Melanesia, which introduced a new approach to ethnographic research. He spent two years in the field, working in the Trobriand language, and systematically recorded not only the idealized systems of rules, values and ceremonies but also the daily practices of social life. Influenced by the sociology of Durkheim, he conceived of the Trobrianders as constituting a social system with institutions that sustained each other and served to meet a series of basic needs. But he did not provide a merely idealized account of the social order, insisting rather that even in small-scale and homogeneous communities social practices diverged from the rules and individuals engaged in strategic behaviour to maximize personal advantage.

This form of fieldwork, which came to be termed 'participant observation', eventually became the standard mode of ethnographic research. In particular, the British school of social anthropology exploited the potential of this method and produced a series of classic ethnographies that may prove to be the most enduring achievement of twentieth century social and cultural anthropology (see e.g. Firth 1936; Evans-Pritchard 1937; Malinowski 1922; 1935; Turner 1957). Some regions of Africa, Indonesia, Melanesia and the Amazon were gradually covered by a set of interlinked ethnographic studies that provided a basis for intensive regional comparison.

The ethnographies produced between about 1920 and 1970 were typically holistic in conception. The guiding notion was that the institutions of the society under study formed an integrated and self-regulating system. As a heuristic device this was undoubtedly fruitful, since it directed attention to the links between different domains of social and cultural life and resulted in rounded accounts of communities. However, this perspective tended to exclude history and social change, and it was not adapted to the investigation of the effects of the colonial institutions that impinged on local social life. From the 1960s, ethnographers increasingly began to develop historical perspectives, drawing on oral traditions as well as archival sources, particularly as more studies were undertaken in peasant societies in Europe and the Near and Far East.

Comparison and explanation

Ethnography was perhaps the most successful enterprise of social and cultural anthropology, but what was the purpose of piling up meticulous ethnographies that dealt mainly with small and remote communities? There were four possible responses to this challenge. The first, historically, was the evolutionist notion that living so-called primitive peoples would provide insights into the ways of life of our own ancestors. Second, drawing on the social sciences (particularly after 1920), many anthropologists argued that ethnographic research and comparison would permit the development of genuinely universal social sciences, which embraced all the peoples of the world, and did not limit themselves to the study of modern western societies. Third, particularly under the influence of ethnology, and later sociobiology, some anthropologists believed that comparative ethnography would reveal the elements of a universal human nature. Finally, humanists, often sceptical about generalizations concerning human behaviour, and critical of the positivist tradition, argued that the understanding of strange ways of life was valuable in itself. It would extend our appreciation of what it means to be human, inculcate a salutary sense of the relativity of values, and extend our sympathies.

The evolutionist faith was that the social and cultural history of humankind could be arranged in a series of fixed stages, through which populations progressed at different speeds. This central idea was badly shaken by the critiques of the Boasians and other scholars in the early twentieth century, but it persisted in some school of archaeology and was sustained by Marxist writers. There have been attempts to revive a generalized evolutionist history in a more sophisticated form (e.g. Gellner 1988). There have also been detailed studies of type cases designed to illuminate evolutionary processes. Richard Lee (1979) undertook a detailed account of !Kung Bushman economic life, for example,

with the explicit aim of seeking clues to the way of life of Upper Palaeolithic foraging populations. His study revealed that the !Kung could sustain a viable way of life using simply technologies in a marginal environment, and the details of !Kung social and economic organization were widely referred to as a paradigmatic example of hunter-gatherer life now and in the distant past (Lee 1979; Lee and DeVore 1968). An influential critique has argued that on the contrary the !Kung are to be understood in terms of their particular modern history. They are the heirs of centuries of contact with Bantu-speaking pastoralists and with European colonists, and their way of life represents a defensive adaptation to exploitation (Wilmsen 1989.) Others argued that the culture of the !Kung could best be understood as a local example of a specific cultural tradition, shared by pastoralist Khoisan peoples as well as other Kalahari Bushmen groups. These critiques are reminiscent of the Boasian critiques of the evolutionist theories of their day.

A related tradition was concerned rather with human universals, and with the relationships between human capacities and forms of behaviour and those of other primates. Since the mid-1970s the sociobiological movement has given a fresh impetus to this project, combining the ethological emphasis on human nature with a theory of selection: institutions (such as the incest taboo) could be explained in terms of their evolutionary payoff. The social and cultural anthropologists were in general more impressed with the variability of customs and the speed with which cultures could change, and objected to the down-playing of cultural variation which this programme required.

An alternative approach to human universals was offered by the structuralism of Claude Lévi-Strauss, who argued that common intellectual processes—determined by the structure of the human mind—underlay all cultural products (see e.g. Lévi-Strauss 1963; 1977). Lévi-Strauss was inspired by structural linguistics, but more recent approaches draw rather on modern theories of cognition.

Social science approaches were dominant in social and cultural anthropology for much of the twentieth century, and fitted in with the behaviourist, positivist approaches favoured more generally in the social sciences. In Europe, the term social anthropology became current, reflecting the influence of the Durkheimian tradition of sociology. Ethnographic studies were typically written up in a 'functionalist' framework, that brought out the interconnections between institutions in a particular society. Some were also influenced by Marxist currents of thought in the 1960s and 1970s. Since the mid-1980s, individualist sociologies have become more popular, but the structuralist tradition also persists, and European scholars are more open than formerly to ideas emanating from American cultural anthropology (see Kuper 1992). Many American anthropologists were particularly interested in psychology, and a whole specialism developed that attempted to apply psychological theories in non-western settings. Initially the main interest was in socialization, but recently there has been more emphasis upon the study of cognition (D'Andrade 1994).

Attempts were also made to develop typologies of societies, religions, kinship and political systems, etc. (e.g. Fortes and Evans-Pritchard 1940). In the USA, G.P.Murdock produced a cross-cultural database to permit the testing of hypotheses about the relationships between particular variables, such as family form and economy, or between the initiation of young men and the practice of warfare, and so on (Murdock 1949). There

is also a long tradition of regional cultural comparison, that takes account of historical relationships and seeks for local structural continuities.

Boas and his students tended to emphasize the variety of local cultural traditions and the accidental course of their development. Some of his most creative associates came to see cultural anthropology as one of the humanities, and this became the dominant cast of American cultural anthropology in the last decades of the twentieth century. Its leading exponent is Clifford Geertz, who argued generally that 'interpretation' rather than 'explanation' should be the guiding aim of cultural anthropology (Geertz 1973). Anthropologists of this persuasion are sceptical about social science approaches, harbour a suspicion of typologies, and reject what they describe as 'reductionist' biological theories. A major early influence was the humanistic linguistics of Edward Sapir, but later other movements in linguistics, hermeneutics and literary theory made converts. Respect for foreign ways of thinking also induced a critical and reflexive stance. Claims for the superiority of a western rationalist or scientific view of the world are treated with grave suspicion (see Clifford and Marcus 1986).

Recent developments

The broad field of anthropology is sustained by its ambition to describe the full range of human cultural and biological variation. The ethnographic record provides a rich documentation of the cultural variety of humanity. Archaeology traces the full sweep of the long-term history of the species. Biological anthropology studies human evolution and biological variation. The use to which these empirical investigations are put are many and diverse. Evolutionist approaches attempt to find common themes in the history of the species; social and psychological anthropologists engage in a dialogue with contemporary social science, confronting the models current in the social sciences with the experiences and models of people in a great variety of cultural contexts; and a humanist tradition aspires to provide phenomenological insights into the cultural experience of other peoples. Once criticized as the handmaiden of colonialism, anthropology is increasingly a truly international enterprise, with major centres in Brazil, Mexico, India and South Africa, where specialists concern themselves mainly with the study of the peoples of their own countries. In Europe and North America, too, there is a lively movement that applies the methods and insights of social and cultural anthropology to the description and analysis of the western societies that were initially excluded from ethnographic investigation.

Applied anthropology developed in the 1920s, and was initially conceived of as an aid to colonial administration. With the end of the European colonial empires, many anthropologists were drawn into the new field of development studies. Others began to apply anthropological insights to problems of ethnic relations, migration, education and medicine in their own societies. As local communities of anthropologists were established in formerly colonial societies, they too began more and more to concern themselves with the application of anthropology to the urgent problems of health, demography, migration and economic development. Medical anthropology is today probably the largest speciality within social and cultural anthropology, and a majority of

American PhDs in anthropology are now employed outside the academy.

anxiety

The term anxiety is currently used in psychology and psychiatry to refer to at least three related, yet logically different, constructs. Although most commonly used to describe an unpleasant emotional state or condition, anxiety also denotes a complex psychophysiological process that occurs as a reaction to stress. In addition, the concept of anxiety refers to relatively stable individual differences in anxiety proneness as a personality trait.

Anxiety states can be distinguished from other unpleasant emotions such as anger, sorrow or grief, by their unique combination of experiential, physiological and behavioural manifestations. An anxiety state is characterized by subjective feelings of

tension, apprehension, nervousness and worry, and by activation (arousal) and discharge of the autonomic nervous system. Such states may vary in intensity and fluctuate over time as a function of the amount of stress that impinges on an individual. Calmness and serenity indicate the absence of anxiety; tension, apprehension and nervousness accompany moderate levels of anxiety; intense feelings of fear, fright and panic are indicative of very high levels of anxiety.

The physiological changes that occur in anxiety states include increased heart rate (palpitations, tachycardia), sweating, muscular tension, irregularities in breathing (hyperventilation), dilation of the pupils, and dryness of the mouth. There may also be vertigo (dizziness), nausea, and muscular skeletal disturbances such as tremors, tics, feelings of weakness and restlessness. Individuals who experience an anxiety state can generally describe their subjective feelings, and report the intensity and duration of this unpleasant emotional reaction.

Anxiety states are evoked whenever a person perceives or interprets a particular stimulus or situation as potentially dangerous, harmful or threatening. The intensity and duration of an anxiety state will be proportional to the amount of *threat* the situation poses for the individual and the persistence of the individual's interpretation of the situation as personally dangerous. The appraisal of a particular situation as threatening will also be influenced by the person's skills, abilities and past experience.

Anxiety states are similar to fear reactions, which are generally defined as unpleasant emotional reactions to anticipated injury or harm from some external danger. Indeed, Freud regarded fear as synonymous with 'objective anxiety', in which the intensity of the anxiety reaction was proportional to the magnitude of the external danger that evoked it: the greater the external danger, the stronger the perceived threat, the more intense the resulting anxiety reaction. Thus, fear denotes a process that involves an emotional reaction to a perceived danger, whereas the anxiety state refers more narrowly to the quality and the intensity of the emotional reaction itself.

The concept of anxiety-as-process implies a theory of anxiety as a temporally ordered sequence of events which may be initiated by a stressful external stimulus or by an internal cue that is interpreted as dangerous or threatening. It includes the following fundamental constructs or variables: stressors, perceptions and appraisals of danger or threat, anxiety state and psychological defence mechanisms. Stressors refer to situations or stimuli that are objectively characterized by some degree of physical or psychological danger. Threat denotes an individual's subjective appraisal of a situation as potentially dangerous or harmful. Since appraisals of danger are immediately followed by an anxiety state reaction, anxiety as an emotional state is at the core of the anxiety process.

Stressful situations that are frequently encountered may lead to the development of effective coping responses that quickly eliminate or minimize the danger. However, if people interpret a situation as dangerous or threatening and are unable to cope with the stressor, they may resort to intraphsychic manoeuvres (psychological defences) to eliminate the resulting anxiety state, or to reduce its level of intensity.

In general, psychological defence mechanisms modify, distort or render unconscious the feelings, thoughts and memories that would otherwise provoke anxiety. To the extent that a defence mechanism is successful, the circumstances that evoke the anxiety will be less threatening, and there will be a corresponding reduction in the intensity of the

anxiety reaction. But defence mechanisms are almost always inefficient and often maladaptive because the underlying problems that caused the anxiety remain unchanged.

While everyone experiences anxiety states from time to time, there are substantial differences among people in the frequency and the intensity with which these states occur. Trait anxiety is the term used to describe these individual differences in the tendency to see the world as dangerous or threatening, and in the frequency that anxiety states are experienced over long periods of time. People high in trait anxiety are more vulnerable to stress, and they react to a wider range of situations as dangerous or threatening than low trait anxiety individuals. Consequently, high trait anxious people experience anxiety state reactions more frequently and often with greater intensity than do people who are low in trait anxiety.

To clarify the distinction between anxiety as a personality trait and as a transitory emotional state, consider the statement: 'Ms Smith is anxious'. This statement may be interpreted as meaning either that Smith is anxious *now,* at this very moment, or that Smith is *frequently* anxious. If Smith is 'anxious now', she is experiencing an unpleasant emotional state, which may or may not be characteristic of how she generally feels. If Smith experiences anxiety states more often than others, she may be classified as 'an anxious person', in which case her average level of state anxiety would generally be higher than that of most other people. Even though Smith may be an *anxious person,* whether or not she is *anxious now* will depend on how she interprets her present circumstances.

Two important classes of stressors have been identified that appear to have different implications for the evocation of anxiety states in people who differ in trait anxiety. People high in trait anxiety are more vulnerable to being evaluated by others because they lack confidence in themselves and are low in self-esteem. Situations that involve psychological threats (that is, threats to self-esteem, particularly ego-threats when personal adequacy is evaluated), appear to be more threatening for people high in trait anxiety than for low trait anxious individuals. While situations involving physical danger, such as imminent surgery, generally evoke high levels of state anxiety, persons high or low in trait anxiety show comparable increases in anxiety state in such situations.

Individuals very high in trait anxiety, for example, psychoneurotics or patients suffering from depression, experience high levels of state anxiety much of the time. But even they have coping skills and defences against anxiety that occasionally leave them relatively free of it. This is most likely to occur in situations where they are fully occupied with a non-threatening task on which they are doing well, and are thus distracted from the internal stimuli that otherwise constantly cue state anxiety responses.

aptitude tests

Aptitude tests are standardized tasks designed to indicate an individual's future job proficiency or success in training. Some tests have been specifically developed for this purpose (for example, name and number comparison tests for selecting clerical workers), while others have been borrowed from educational, clinical and research use (for example, Cattell's 16 Personality Factor Questionnaire). Tests may be administered to an individual or to a group. The main types now in use are of intellectual, spatial, mechanical, perceptual and motor abilities, and of interests and personality traits.

Tests must be shown to be job-relevant, the most persuasive evidence usually being the demonstration of a relationship between pre-entry tests scores and later training or job performance (predictive validity). For example, Flanagan (1948) showed in one study that none of the very low scorers (grade 1) on a pilot aptitude test battery graduated from pilot training, as against some 30 per cent of average scorers (grade 5) and over 60 per cent of the very high scorers (grade 9). Ghiselli (1973) concluded that aptitude tests are generally better at predicting training success rather than job proficiency, but that for every type of job there is at least one type of test which gives a moderate level of prediction. Combining tests into a battery would tend to improve prediction.

Until the 1970s it was generally accepted that a test had to show predictive validity in each specific instance of use, but many psychologists now believe that validity can be generalized given an adequate specification of the test and of the job. Thus, an organization need no longer rely solely on its own research, since evidence from a number of organizations can be collected to serve as a national or international database.

The financial benefit to an organization from test use depends on other factors besides validity, notably on how selective it can be when choosing job applicants and the nature of the job (variation in performance in monetary terms). The reductions in costs or increase in profits can be impressive; Schmidt *et al.* (1979) estimated that the selection of computer programmers using a programmer aptitude test could produce productivity gains of some 10 billion dollars per year for the US economy.

There has been increasing criticism of aptitude tests in personnel selection because of alleged unfairness to minority groups. Some of the specific instances raised in the law courts indicated that the necessary validation research had not been carried out; test use was therefore potentially unfair to all applicants and disadvantageous to the organization. A number of statistical techniques are available to help evaluate test fairness, and increasingly the developers and suppliers of tests provide information about the performance of different groups (defined by gender and ethnicity, for example) and other data relevant to equal opportunities.

Most aptitude tests are paper-and-pencil. Only a small proportion involve other types of material or apparatus. Recent developments include the production of computerized versions of existing tests, and computer scoring. It is likely that tests designed to benefit

from computer technology, for example tests involving the display of dynamic material on the visual display unit, and the interpretation of test results using computer software, for example expert systems, will become common (see, e.g. Bartram 1989).

archaeology

Archaeology often appears to mean different things, from the particular to the general, in different contexts. At one extreme it can refer to the recovery of ancient remains by excavation, 'digging up pots and bones'. But even field archaeology now includes a wide range of activities from survey, the cleaning and recording of industrial machines (industrial archaeology), underwater archaeology to air photography. Excavation itself involves both archaeological concepts such as context, association and assemblage, and external techniques, such as methods of probing below the surface soil with magnetometers, pollen analysis to reconstruct past environments, and data processing with computers. More generally, archaeology is often used to refer to what archaeologists do, including what is more property termed prehistory or history. All reconstruction of the past which is based on material remains other than written records might be termed archaeology. Yet within historical archaeology use is often made of written records as part of the interpretative process. The boundary between archaeology and history (including prehistory) is blurred, because the interpretation of layers on a site is closely dependent on accumulated knowledge about what went on at any particular place and time in the past. Since there are few Pompeiis, and archaeological remains are typically fragmentary and ambiguous, the burden on theory is great. Theories and paradigms often change with little contradiction from the data. There is much scope for historical imagination.

Views differ as to the degree of rigour and certainty that can be obtained in reconstructing the past from archaeological remains, at least partly in relation to whether one thinks archaeology is really an historical or an anthropological science. Unfortunately, the two approaches have normally been opposed. Those who claim that the purpose of archaeology is historical emphasize the particularity of past cultures, the unpredictability of human action, and the role of individuals. They state that each past culture has its own value system which it is difficult for archaeologists to reconstruct with any confidence. Prehistory and archaeology are interpretative by nature. For those who claim that 'archaeology is anthropology or it is nothing', and who believe in the cross-cultural method, allied with positivism and with laws of evolution and systematic relationships, rigorous explanation of events in past societies is feasible. The concern with scientific explanation has been particularly strong in the USA, but the two views of archaeology, as history or science, have a long tradition in the discipline.

The history of archaeology

Speculation about the human past began in classical antiquity, but investigation of monuments and artefacts dates back to the Renaissance and increased markedly in the eighteenth and nineteenth centuries as part of national interests, pride and identity. This early archaeology had its origin in the study of oriental and classical antiquities such as Pompeii, the recording of European monuments such as Stonehenge and Carnac, and the interest in human origins as an outcome of developments in geology and biology.

The initial concern was to establish a chronological sequence, and in the early nineteenth century in Denmark C.J.Thomsen grouped antiquities into stone, bronze and iron and gave them chronological significance, while J.J.A.Worsaae provided stratigraphical evidence for the sequence. The scheme was argued on ethnographic grounds to relate to a development from savagery to civilization. This idea of Sven Nilsson was, in the second half of the nineteenth century, developed by Sir Edward Tylor and Lewis H.Morgan, and it influenced Marx and Engels. An evolutionary emphasis in archaeology was, in the debates about the origins of humankind, also closely linked to Charles Darwin.

In this early period of archaeology, an evolutionary approach was closely allied to a cross-cultural emphasis, scientific optimism, and notions of progress from barbarism to industrial societies. Yet in the early twentieth century, and particularly after the First World War, the main concern in archaeology became the building up of local historical sequences, the identification of cultural differences and the description of the diffusion and origin of styles and types, V.Gordon Childe crystallized earlier German and English uses of the term culture and defined it as a recurring association of traits in a limited geographical area. These spatial and temporal units became the building blocks for the definition of local historical sequences and the diffusion of traits. Childe described the prehistory of Europe as at least partly the result of diffusion from the Near East, 'ex Oriente lux'.

But Childe was already responsible for reintroducing an evolutionary emphasis in European archaeology by taking up Morgan's scheme, while in the USA Julian Steward

and Leslie White embraced similar ideas. Rather than describing sites, processes were to be examined. In particular, attention focused on the economic relationships between a site and its environment. The work of Grahame Clark in Europe and Willey and Braidwood in the USA pioneered this new, functional, integrative approach which owed much to developments in anthropology. The discovery of physical dating methods such as radiocarbon (C^{14}) measurement freed the archaeologist from a reliance on typology, types, cultures and associations in establishing chronologies.

A full mixture of evolutionary theory, anthropology, and science in archaeology was attempted in the 'New Archaeology', a development of the 1960s and 1970s, spearheaded by Lewis Binford in the USA and David Clarke in Britain. Although there were many differences between these and other New Archaeologists, the overall concern was to introduce scientific, rigorous methods of explanation into archaeology. Rather than describing what happened in the past (the perceived view of earlier, historical approaches in archaeology), they tried to explain why events occurred. Ethnography and anthropology provided the theories for the explanation of past events, and a subdiscipline, 'ethnoarchaeology', developed in order to study more closely the relationship between material culture residues and processes in the living world. From such studies they hoped to build laws of cultural process from which particular archaeological occurrences could be deduced. They frequently referred to positivism and Hempel's hypothetico-deductive method.

The current scene

Much archaeology, particularly in the USA, remains within the grip of ecological functionalism, evolutionary theory and positivism, in the aftermath of the New Archaeology. The enduring concerns have been with process, the application of systems theory, positivism and scientific methods, including the widespread use of computers for the storing and sorting of field data, statistical manipulations, taxonomy and simulation. Cemeteries are examined in order to identify age, sex and status groupings as part of 'social archaeology', and settlement data are searched for organizational clues. Evolutionary theory is referred to in the definition of bands, tribes, chiefdoms and states and in discussions of the transformation of these categories through time. There are both Neo-Darwinian and Neo-Marxist schools.

Yet for many archaeologists, particularly in Europe, archaeology remains an historical discipline. Many field archaeologists, funded by central or local government or by development contractors, find that the academic rhetoric of their university colleagues has little relevance to their problems and interests. The split between theory and application is widening. Similarly, museum curators are aware that popular interest centres on local and regional historical continuity, and on the material achievements of foreign cultures, rather than on cross-cultural laws of social process. In addition, many academic archaeologists cling to the historical tradition in which they had been taught and reject the claims of the New Archaeology. An emerging feeling in archaeology is that the old battle between historical and scientific-anthropological views of the past is inadequate. The concern is to allow the particularity of historical sequences, and the

individuality of culture, while at the same time focusing on social process and cultural change.

Aristotle (384–322 BC)

Aristotle was born in Stagira, a small Greek town on the coast of the Chalcidice peninsula in the northern Aegean, close to the Macedonian kingdom. His father was court physician to Amyntas III of Macedon. He studied with Plato in Athens from 367 to 348 BC, then moved to the court of Hermias of Atarneus, in the Troad, another pupil of Plato, one of whose relatives became Aristotle's wife. After a period in Lesbos, Aristotle joined Philip of Macedon's court as tutor to Alexander in 342. After Philip's death in 335 he returned to Athens and stayed there until Alexander's death in 323 when the anti-Macedonian reaction forced him to withdraw to Chalcis, the Euboean city from which his mother had come.

Aristotle was thus exposed both socially and intellectually to contradictory influences. Socially, he belonged to the Greek polis in the last generation of its struggle to retain autonomy—a limited local autonomy in the case of Stagira, the claim of a fading imperial power in the case of Athens—but at the same time he had firsthand experience of living in the new form of society which was to succeed the polis. Intellectually, his father was part of the empiricist tradition of Greek medicine with its emphasis on careful reporting and observation as the only basis for accurate prediction of the likely future course of a disease, while his teacher Plato believed that the visible world was merely an imperfect reflection of a reality which could be apprehended only intellectually, and thought it the right and duty of the philosopher to reason out the correct course for humankind and society and then—if only he could—impose his prescriptions on his fellow-citizens.

This second source of tension in Aristotle's life, between opposing epistemologies, was much more productive than the first. It led him firmly to assert the intellectual satisfactions, as well as the practical utility, of studying apparently low forms of animal life and engaging in the messy activity of dissection (Lloyd 1968), and to extend the methods of research developed in medicine to the whole field of biology; it also led him to reflect systematically on logic and processes of reasoning, both human and animal.

The characteristics which humans shared with animals, instead of being seen in a negative way as inescapable defects (mortality) of a 'lower nature' which had to be subdued, became a basis for understanding, a transformation with particularly far-reaching implications for psychology. At the same time the principles of argument which had been being worked out piecemeal in law courts, assembly debates, medical practitioners' disputes and treatises (see Lloyd 1979), mathematical proofs and philosophical dialectic were drawn together in a systematic way which helped to establish methodology or 'second-order thinking, thinking about thinking' (Elkana 1981) as a problem in its own right. Aristotelian logic eliminated many of the sophistic puzzles that had perplexed earlier philosophers, extended the idea of 'proof' from mathematics to other areas of scientific and philosophical thought, and even, by implication, anticipated modern concern with the relation between logic and language. Aristotle's comprehensive interests and systematic organization of research provided the first foundations for the idea of a university as a place where students are taught how to extend knowledge in all its branches. Discussion and criticism of earlier views was part of the method.

In principle, Aristotle's procedure of taking earlier opinions, particularly those of Plato, and criticizing them on the basis of observation, coupled with his experience of the Macedonian court, might have produced important transformations in political theory. In practice it hardly did so; Aristotle's political and social thought remained enclosed within the frame of the city-state. His view that *chremastiké,* the art of money-making, was morally wrong prevented him from developing an understanding of the growing importance of trade and commodity production in the economy, and in general his empirical attitude tended to lead to a confusion between the statistically normal and the normative. Since domination of males over females, parents over children and masters over slaves was so widespread, it must be right. Belief in the superiority of Greeks over barbarians led Aristotle to assert that some ethnic groups are naturally fit only for slavery, a view which had a long career in the service of racism, though Aristotle himself thought of culturally rather than physically transmitted qualities. The view that the family, observable in animals as well as humans, is the basic form of society had already been put forward by Plato in the *Laws* (earlier Greek thinkers had pictured primitive human society as a herd rather than a family: Cole 1967). Aristotle took it up and extended it, producing the model of development from family to *gens* and from *gens* to phratry, tribe and city which was to have such an important influence on anthropological kinship theory in the nineteenth and early twentieth centuries. Possibly the growing importance of private life in fourth-century Greece, particularly for those not directly involved in politics, helped to make this view of kinship ties as the basic bonds of society attractive (see Humphreys 1983a, 1983b).

The fact that Aristotle lived an essentially 'private' life (whatever his relations with the ruling Macedonian elite may have been) is also responsible for his marked interest in the study of friendship, which plays a large part in his *Ethics.* Friends were the philosopher's reference-group, the people who assured him that the philosophical life was indeed the best life; Aristotle's discussion of friendship supplied the basis for the stoic idea of the 'cosmopolitan' community of wise men. At the same time Aristotle's relations with the Macedonians had given him plenty of experience of patronage and friendship between unequals: his acute remarks here were to prove useful to later Hellenistic philosophers

grappling with the problems of royal power and patronage.

There is no doubt that Aristotle was a shrewd observer of human behaviour. He firmly rejected the Socratic view that virtue is knowledge, on the grounds that people often know what they should do but fail to do it; what we call virtues are consistent patterns of behaviour, though conscious thought must also enter into them. How the habit of virtuous behaviour is to be inculcated Aristotle does not really tell us. He accepted social conflict as inevitable; rich and poor have opposed interests and the best way to achieve stability in society is to have a large middle class of intermediate wealth who will hold the balance between them. This emphasis of the middle class as the key element in society is part of his more general belief that virtue and right action is a mean between two extremes, an adaptation of the Delphic maxim *méden agan,* 'nothing to excess'.

Medical theory helped Aristotle fit a much more liberal attitude than Plato's towards the arts into this framework. Though care must be exercised in choosing music and stories for children, adults can benefit from having their emotions stirred by music and tragedy because this purges them of excess emotion. In an important book, Jones (1962) has argued that Aristotle's remarks on tragedy have been misunderstood in the European tradition and, when correctly interpreted, can throw light on the difference between Greek conceptions of the person and of action and those of the modern western world.

In a sense Aristotle seems to be a consolidator rather than an innovator, a systematizer and synthesizer of ideas originally raised by others. Nevertheless, the new fields of research he opened up, his contributions to methodology and scientific terminology, and the intelligence of his criticisms of earlier views and proposed solutions to philosophical problems make him a founding figure in many branches of research. The works which survive were written for teaching purposes rather than for the general public: their inelegant, rather jerky style gives an attractive impression of an unpretentious thinker who faced difficulties and objections to his own views honestly.

art, sociology of

The term sociology of art usually serves as a convenient, if confusing, shorthand for sociology of the arts or, sometimes, sociology of art and literature. In fact, the sociology of the visual arts is probably far less developed than the sociology of literature, drama or even film. The generic nature of the subject matter of this subdiscipline does unavoidably create difficulties for analysis, since it is not always possible to draw exact parallels between, say, music and the novel, in their social or political contexts.

The sociology of art is an extremely diverse body of work. There is no single, or even dominant, model of analysis or theory of the relationship between the arts and society. In Britain and in some other European countries, Marxist and neo-Marxist approaches have been particularly influential since the mid-1970s, though there are plenty of studies and contributions by non-Marxist scholars too; in the USA, Marxism is rarely the foundation for a sociology of the arts. It is useful to begin to survey work in this area by starting from these two very different traditions.

The American sociology of art is often referred to as the production-of-culture approach. It is very much in the mainstream of sociological analysis, and focuses on the study of the institutions and organizations of cultural production (see Becker 1982; Coser 1978; Kamerman and Martorella 1983; Peterson 1976). The interest is on the social relations in which art is produced. Sociologists have looked at the role of gatekeepers (publishers, critics, gallery-owners) in mediating between artist and public; at the social relations and decision making processes in a college of art, or an opera company; or at the relation between particular cultural products (for example, photographs) and the social organizations in which they are produced (Adler 1979; Bystryn 1978; Rosenblum 1978). The emphasis is often, though by no means exclusively, on the performing arts,

where the complexity of social relations merits analysis; in Britain, the performing arts take second place to literature as a central focus for sociologists.

The Marxist tradition

A criticism sometimes levelled at the so-called production-of-culture approach is that it often ignores the cultural product itself, taking it simply as a given object, and paying no attention to its content, symbolic nature, or conventions of representation. Work in the Marxist tradition, on the other hand, has increasingly come to recognize the importance of looking critically and analytically at the novel, or painting, or film, as well as at its conditions of production. Marxist aesthetics has moved away from the simple and misleading metaphor of base-and-superstructure, with its constant risk of an economic reductionist account of culture, and of conceiving of literature and art as merely 'reflections' of class or economic factors. Here the earlier work of continental European authors (Gramsci, Adorno, Althusser, Goldmann) has been crucial in refining the model, stressing the mediating levels of social group, individual (authorial) consciousness and experience, and, more recently, of textual specificity. In this last case, there has been a fruitful incorporation of structuralist, semiotic, and psychoanalytic insights into a more sociological perspective, which has facilitated an attention to such things as narrative, visual imagery, cinematic techniques and conventions, and televisual codes. Thus, as well as demonstrating that, for example, a television news programme is produced in the particular context of capitalist social relations, governmental or commercial financing, and professional and political ideologies, it is also possible to look at the 'text' itself (the programme, in this case), and to analyse the ways in which meanings (aesthetic, political, ideological) are constituted in a variety of ways through visual and aural codes, narrative commentary, camera angles and so on.

The strengths of the sociology of art to date, particularly in the USA and in Britain, have been, first, the development of a methodology for the study of the institutions and practices of cultural production and, second, the analysis of culture as part of a wider social and historical framework. The sociology of cultural production and the sociology of the text, as complementary analyses, provide a valuable corrective to the more traditional, uncritical approaches to the arts dominant in art history, literary criticism, and aesthetics. It is worth noting, however, that a major contribution to the development of the sociology of art, at least in Britain, has come from people working in those disciplines. Concerned to expose the ideological nature of their subject matter as well as of their disciplines, they have argued that the 'great tradition' and the 'literary canon' are much better perceived as social and historical products, constituted in particular institutions and through specific values, than as presenting any 'natural' or 'transcendent' values (Eagleton 1976; Widdowson 1982).

Another area of great importance to the sociology of art is the study of reception—of audiences and their responses. This aspect of culture has so far been neglected, although developments in literary criticism in the USA, in Germany and in Scandinavia (hermeneutics, reception-aesthetics, psychoanalytic approaches) provide the possibility of an approach to the constitution of meaning in the reader/viewer. It is now realized by

several sociologists that the critical study of texts needs to be supplemented by a sociology of readers and audiences, their nature, constitution, and modes of reception (Eco 1980).

The sociological approach to the arts has been able to demonstrate the contingent, and class-related, development and separation of 'high art' from 'popular culture', and thus to render more problematic the elitist conceptions of art which obtain among those involved in support and funding for the arts, as well as in society in general (including, incidentally, among many of its sociologists). The notion of 'cultural capital' (Bourdieu 1984), suggesting the use made by dominant social groups of specific forms of culture as a way of securing their identity by the exclusion of other groups, is a useful way of demonstrating the historical and continuing production of boundaries and aesthetic judgements in culture.

Recognition of the interdisciplinary character of the sociology of art must also include mention of work by feminist critics and historians, who have noted and challenged the exclusion of women from both the production of art and the history of art (Moers 1977; Parker and Pollock 1981; Pollock 1982). The answer to the question 'why have there been no great women artists?' (Nochlin 1973) is certainly a sociological or social-historical one, and feminist analysis enables us to comprehend the one-sided nature of the production of culture, in terms of gender, and also the dominance of patriarchal ideology in artistic representation. The way in which women (and men) are represented in art and literature is both a product of their actual position in society and the ideologies which maintain this, and also a contributing factor *to* those ideologies. And as post-colonial criticism has shown, an exactly parallel argument can be made about ethnic minorities and non-western culture (Hiller 1991; Lipparet 1990; Said 1978). For culture is not simply a reflection of social structures: it is also the producer of meanings and the determinant and support of ideologies. In this sense, the metaphor of base and superstructure is clearly reversible, since art and culture can also sustain, and in some cases subvert, the *existing* order.

artificial intelligence

Research in artificial intelligence (AI) represents an attempt to understand intelligent behaviour (and its prerequisites: perception, language use, and the mental representation of information) by making computers reproduce it. It has historical precedents in the work of Pascal, Leibniz and Babbage, who all devised schemes for intelligent machines that were impractical, given the mechanical components from which it was envisaged that those machines would be constructed. The existence of AI as an independent discipline, however, can be traced to the invention of the digital computer, and, more specifically, to a conference at Dartford College, New Hampshire, in 1956. At that conference, Allen Newell, Cliff Shaw and Herbert Simon (see, e.g. Newell *et al.* 1957) described the use of heuristic, rule of thumb, procedures for solving problems, and showed how those procedures could be encoded as computer programs. Their work contrasted sharply with immediately preceding attempts to explain intelligent behaviour by modelling the properties of brain cells.

Newell *et al.*'s work led to the development of more sophisticated programming languages (in particular John McCarthy's LISP), and their general approach, dubbed *semantic information processing* by Marvin Minsky, was applied to fields as diverse as visual object recognition, language understanding and chess playing. The advent of larger, faster computers forced AI researchers to confront the problem of whether their programs would scale up so that they could operate in the real world, rather than on small-scale laboratory tasks. Could a program that conversed about wooden blocks on a table top be generalized so that it could talk about poverty in the developing world, for example?

Often the answer was: no. Tricks that worked in a limited range of cases would fail on other cases from the same domain. For example, ideas used in early object recognition programs were later shown to be restricted to objects with flat surfaces. Many aspects of

intelligence came, therefore, to be seen as the exercise of domain-specific knowledge, which had to be encoded in detail into computer programs, and separately for each subdomain. This conception of intelligence led to the construction of *expert systems.* DENDRAL (see Lindsay *et al.* 1980), which computed the structure of complex organic molecules, and MYCIN (see Shortliffe 1976), which diagnosed serious bacterial infections, were the first such systems, and they remain among the best known. Expert systems have become commercially important, usually in the guise of sophisticated *aides memoires* for human experts, rather than as replacements for them. One of their principal strengths is their ability to process probabilistic information, which contributes to many kinds of diagnosis.

A different attack on the semantic information processing research of the 1960s came from David Marr (see, in particular, Marr 1982), who argued that AI researchers had failed to provide a *computational theory* of the tasks their machines were trying to carry out. By a computational theory he meant an account of what outputs those machines were trying to produce from their inputs, and why. Marr wanted to combine evidence from neurophysiology and perceptual psychology with computational techniques from AI, and other parts of computer science, to produce a detailed and explanatory account of human vision. Although he did not wholly succeed before his untimely death in his mid-thirties, his work on the lower levels of the human visual system remains the paradigmatic example of successful research in cognitive science.

Marr's computational models contained units that were intended to mimic the properties of cells in the visual system. He therefore reintroduced techniques that had been sidelined by Newell *et al.*'s information processing approach. *Connectionism* is a more direct descendant of the earlier neural modelling approach. However, the units from which connectionist models are built are not based on specific classes of nerve cells, as those in Marr's models are.

Marr questioned whether traditional AI could generate *explanations* of intelligent behaviour, and connectionists asked whether it could model *biological,* and in particular human, intelligence. Not surprisingly, therefore, many AI researchers in the 1980s embraced the engineering side of the discipline, and focused their attention on its applications. This orientation was also sensible at a time when funding was more readily available for projects with short- to intermediate-term returns. Ideas from AI, albeit not always in a pure form, found their way into commercial expert systems, learning aids, robots, machine vision and image processing systems, and speech and language technology. Indeed, techniques that have their origin in AI are now widespread in many types of software development, particularly of programs that run on personal computers. Object-oriented programming was first introduced in the AI language SMALLTALK. It is now a staple of programming in C++, one of the standard languages for windows applications.

Learning posed another problem for traditional AI. The semantic information processing approach assumed that the analysis of an ability, such as chess playing, should be at an abstract level, independent of the underlying hardware—person or machine—and independent of how the hardware came to have the ability, by learning or by being programmed. The ability to learn is itself an ability that might be modelled in an AI program, and some AI programs *were* programs that learned. However, a vague unease

that learning was not receiving the attention it deserved grew, in some quarters, to the feeling that machines could never be really intelligent unless they could learn for themselves. Furthermore, the kinds of learning modelled in AI programs were limited. For example, concept learning programs were capable only of making slightly more complex concepts out of simpler ones that were programmed into them. For some kinds of *machine induction* this kind of learning is satisfactory, and it can produce impressive results on large machines. However, it leaves doubts about the limitations of such methods of learning unanswered.

Connectionism, with its techniques of pattern abstraction and generalization, has been seen by many as at least a partial solution to the problems about learning that beset traditional AI. A different approach is based on the analogy between evolution and learning, and on the idea that many types of intelligent behaviour are the product of evolution, rather than of learning in individual animals. *Genetic algorithms* were originally invented by John Holland (see 1992) who showed, perhaps surprisingly, that computer programs can be evolved by a method that parallels evolution by natural selection. The programs are broken into pieces that can be recombined according to fixed rules (as bits of genetic material are recombined in sexual reproduction). The new programs then attempt to perform the to-be-learned task, and the ones that work best are selected to enter the next round, and to leave offspring of their own. As in evolution, this process must be iterated many times if order is to emerge, in the form of a program that can carry out the required task. The use of genetic algorithms is closely allied to the emerging discipline of artificial life, which is broader in scope and more controversial than AI.

Many of the controversies that surround artificial life are philosophical ones, and they often parallel those generated by AI research. Two main questions have been prompted by work in AI. First, can machines really exhibit intelligence, or can they only simulate it in the way that meteorological computers simulate weather systems? Second, if there were intelligent machines, what moral issues would their existence raise? Potentially, intelligent machines are different from weather-predicting computers, since those computers do not produce rain, whereas robots could act intelligently in the real world. The moral question, like all moral questions raised by scientific advances, must be addressed by society and not specifically by AI researchers.

Asiatic Mode of Production

The Asiatic Mode of Production refers to a much debated concept in Marxist social science. In the writings of Marx and Engels (1955; 1970 [1845–6]), discussions of 'Asiatic forms' appear on numerous occasions although almost never in combination with the term 'mode of production', a concept which was not systematized until after Marx's death. Moreover, they employ the term in reference to two quite different phenomena. In the newspaper articles and correspondence on India, the concept would appear to extend and elaborate a more economic version of older eighteenth- and nineteenth-century ideas of 'Oriental Despotism', referring here to the great Asiatic empires with their complex political organization. In the justly famous section of the *Grundrisse der Kritik der politischen Ökonomie* (1857–8), called *Pre-Capitalist Economic Formations* (1964), the concept is used to characterize the most primitive form of state society where a collection of self-sufficient agricultural communities are ruled by a higher instance, the theocratic representative of the higher unity of collectivity—sacralized nature, deity or ancestor—of primitive society. Similarly, economic exploitation is a simple extension of a potential already present in primitive society: 'Surplus labour belongs to the higher community, which ultimately appears as a person' (Marx 1964).

The Oriental Despotic version of the Asiatic Mode concept is that which dominated the intellectual development of the late nineteenth and early twentieth centuries. The Asiatic empires were conceived of as historically stagnant societies dominated by a state class that controlled the totality of the land and organized supra-local irrigation works, but whose economic base consisted of self-sufficient village communities whose contact with one another was minimal and who supported the state-class by means of the taxation of their surplus product. With the emergence of a formalized historical materialism in the work of Engels and the Second International (Kautsky, Plekhanov), the concept became

increasingly linked to a techno-ecological kind of explanation. This tendency reached its climax in the subsequent work of Wittfogel and emerged finally in the hydraulic hypothesis, which posits a causal relation between the ecologically determined necessity of large-scale irrigation and the emergence of the despotic-bureaucratic state machine (Wittfogel 1957). The Asiatic Mode was not a particularly welcome concept among the higher echelons of post-revolutionary Soviet society for obvious reasons, and both Wittfogel and the Asiatic Mode of Production were purged from the Third International, whose project for a Chinese revolution was incompatible with the suggestion that Asia was fundamentally different from the west, that it possessed a stagnant mode of production, or that a bureaucracy could in any way constitute a ruling class.

While the work of Wittfogel significantly influenced American neo-evolutionism (Steward 1955), theoretical discussion of the Asiatic Mode of Production was not again revived until the late 1950s and 1960s, after the Twentieth Congress of the Communist Party officially announced the reopening of Marxist debate. Discussions began first in eastern Europe and then spread to Paris, where they have played a central role in the development of structural Marxist theory in general, and anthropology in particular (Althusser and Balibar 1969 [1965]; Godelier 1969). The new discussion has been based primarily on Marx's *Pre-Capitalist Economic Formations* and has focused on the problem of early state formation in general, the relation between 'primitive' communal forms and class formation, the symbolism of state power and theocracy, and the specifics of 'Asiatic' social forms in evolutionary as well as concrete historical frames of reference (Friedman 1979; Kindness and Hirst 1975; Krader 1975).

associationism

The concept of the association of ideas is as old as Aristotle, but its use as the basic framework for a complete account of mental life is essentially British, beginning with John Locke and ending with Alexander Bain. There were some near contemporary continental associationists and some Scottish philosophers who made considerable but subsidiary use of the concept. They were not as thoroughgoing, or perhaps as single-minded, as the group recognized as British Empiricists.

Locke, Berkeley and Hume used associationism to provide support for the empiricist epistemology they were developing in opposition to Descartes's basically rationalist view. They maintained that knowledge and belief derived from, and could only be justified by, reference to sensory experience, as distinct from the innate ideas and necessary truths argued for by Descartes. They also held that such sense-based experience could be divided into elementary units such as sensations (experiences brought about by the impact of external objects on the senses), images (re-evoked or remembered sensations) and feelings (affective values attached to sensations and images). This resort to atomistic elements was probably made in the belief that such experiences were incorrigible and hence beyond dispute; what I experience on one occasion is not corrected by what I experience on comparable occasions, even though the series may build up a web of experience. This web or set of patterned knowledge is built up as the separate ideas become associated or linked in synchronous groups or chronological chains.

British associationism reached its peak as a psychological system when a series of thinkers, David Hartley, James Mill, John Stuart Mill and Bain, concentrated on erecting a free-standing theory of mental life and not just a psychological foundation for an epistemology.

It is important to note the growing positivist sensationism of the three early philosophers. Locke had assumed a mind or self on which external objects made an impact through the senses; Berkeley accepted the mind or self but denied that we could have any direct knowledge of external objects (all we could directly know were our 'ideas'); Hume went further and claimed that the so-called mind or self was no more than the passage of our 'ideas'.

Hartley, a physician rather than a philosopher, tried to give sensations, images, feelings and their associations a neurophysiological basis. He suggested that the impact of external objects on the senses set up vibrations in the sensory nervous apparatus and that these were experienced as sensations. Images were the result of later minor vibrations, which he called 'vibratiuncles', induced by associated sensations or images. James Mill, an historian and political theorist, abandoned Hartley's premature and rather fantastic neurophysiology but developed the psychological thinking on more systematic and positivistic lines. His treatment was strictly atomistic and mechanical. John Stuart Mill and Alexander Bain softened these tendencies, arguing for 'mental compounds' in the

chemical sense as well as for 'mental mixtures' in which the totality was no more than the sum of the associated elements.

There was much disagreement over the 'laws' or conditions of the association of 'ideas'. It was universally accepted that frequency and contiguity (two or more 'ideas' often occurring together or in close succession) constituted a basic condition, for example 'table' and 'chair' are said to be associated because these two 'ideas' are frequently experienced in conjunction. (Some modern learning theories would call this assumption into question.) In addition to this basic law, some associationists added one or more qualitative laws, such as the 'law of similarity' governing the association of 'dark' and 'black', the 'law of contrast' 'dark' and 'light', and the 'law of cause and effect', 'boiling' with sustained 'heat'. Bain added a 'law of effect' which claimed that an experience followed by another became associated if the latter satisfied a need related to the former; this was given a prominent place in later S-R learning theory.

Though claiming to be based on observation or sensory experience, British associationism was based largely on common sense and anecdotal evidence. Later, von Helmholtz, Wundt, Ebbinghaus; Kulpe, G.E.Muller and others developed experimental methods to provide a sounder empirical basis for somewhat revised associationist theorizing.

attachment

Attachment refers to the tie between two or more individuals; it is a psychological relationship which is discriminating and specific and which bonds one to the other in space and over enduring periods of time. Researchers and clinicians have been particularly concerned with two types of attachment: parental attachment (which sadly, in the literature, usually means *maternal*) and infantile attachment. It is widely agreed that the infants of many vertebrate species become psychologically attached to their parents; human babies first acquire an attachment to their mothers and (usually a little later) significant others during the second half of their first year of life.

Proximity seeking (for example, following) is commonly interpreted as an index of infant-to-parent attachment; other indicators include behaviour in 'strange situations' and activities such as differential smiling, crying and vocalization, as well as protest at separation (see Ainsworth 1973). Multiple criteria are used to specify attachment phenomena because of individual differences in the way attachment is organized and manifested—differences that seem to be related to variations among mothers in their

infant-care practices. Indeed, because the child's attachment system is, in a sense, the reciprocal of the parents', it may be preferable to speak of, say, the mother and young child as forming a single, superordinate attachment system. The delicate and complementary intermeshing of their respective, individual attachment repertoires is such that it is not possible to describe one fully without also describing the other.

There is little agreement on the nature of this powerful motivational process: a plethora of explanatory ideas have been put forward, in the name of learning theory (Gerwitz 1972; Hoffman and Ratner 1973), psychoanalysis (Freud 1946) and ethology (Ainsworth 1973; Bowlby 1969). Bowlby—to take one example—sees attachment behaviour as the operation of an internal control system. Children are biologically predisposed to form attachments. It could be said that they are genetically programmed to respond to social situations and to display forms of behaviour (smiling, crying, clinging, and so on) from the beginning of life up to and beyond the point in time when they make a focused attachment to parental figures. What is new, then, when the infant becomes attached, is not the display of new forms of behaviour or new intensities of social responses, but a pattern of organization of these responses in relation to one significant person. Virtually all the elements in the child's behaviour repertoire become capable of being functionally linked to a controlling system or plan, which is hierarchical in its organization and target-seeking in its effect. The 'target' is defined as the maintenance of proximity to the care-giver, and the hierarchical nature of the organization is revealed in the fact that a particular response can serve a number of different functions in maintaining this proximity.

It is argued (Belsky and Nezworski 1988) that the 1980s witnessed a 'virtual revolution' in our understanding of the child's early development, and in particular a recognition that individual differences measured within the first years of life are predictive of later development. This applies, *inter alia,* to the child's socio-emotional development within the context of his or her attachments (see Herbert 1991). The measurement of the *security* of infant-to-mother attachment (at the end of the first year of life) has come into its own as a predictor of *competence* as far forward as the early school years (see Bretherton 1985).

The preoccupation of researchers and clinicians with the influence of the mother on the infant's development, and the foundational significance of the first attachment has had salutary effects: highlighting the psychological needs of the young child and humanizing substitute child-care arrangements. The cost was a professional ideology, particularly rampant in the 1950s, whereby mothers were inculpated in the causation of psychopathology varying from infantile autism to juvenile delinquency. Rutter (1972), among others, was instrumental in producing a more balanced view of the role of attachment and maternal care in the development of normal and abnormal behaviour.

Mother-to-infant attachment is usually referred to as maternal bonding. Put briefly, it proposed that in some mammalian species, *including our own,* mothers become bonded to their infants through close contact (e.g. skin-to-skin) during a short critical period, soon after birth. This is an awesome claim considering that no other adult human behaviour, and a complex pattern of behaviour and attitude at that, is explained in such 'ethological' terms. To spell it out, the suggestion is that sensory stimulation from the infant soon after its delivery is essential if the mother is to fall in love with her baby.

During the critical hours following birth, tactile, visual and olfactory stimulation of the mother by her baby is thought to be particularly significant.

The close-contact, critical-period bonding theory is said to be justified on two grounds (see Klaus and Kennel 1976). One is rooted in studies of animal behaviour. The ethological support for the bonding doctrine, derived from early experiments with ewes and goats (olfactory imprinting) has not stood the test of time. Nor has evidence from human longitudinal studies comparing mothers who, after giving birth to a baby, have either been separated from it or have been allowed extended skin-to-skin contact with it, supported a 'sensitive' period, 'ethological' explanation. The impact of the doctrine upon the thinking of practitioners in obstetric, paediatric and social work fields has been considerable, particularly in relating bonding failures (allegedly due to early separation experiences) to serious problems such as child abuse. These clinical applications have also been challenged (see Herbert and Sluckin 1985; Sluckin *et al.* 1983). It seems more likely that exposure learning, different forms of conditioning, imitation and cultural factors, all influence the development of mother-to-infant (and, indeed, father-to-infant) attachments and involve a process of learning gradually to love an infant more strongly— a process characterized by ups and downs, and one which is often associated with a variety of mixed feelings about the child.

It is as well to remember that maternal bonding is only one more idea in the long history of child care ideologies. Ideas and prescriptions for the early management of children are like fashions; they have come and gone, like the influence of their proponents.

attitudes

In a classic article published in the mid-1930s, Gordon Allport (1935) contended that the attitude concept was 'the most distinctive and indispensable concept in contemporary social psychology'. While this confident assertion may perhaps be more debatable now, the study of attitudes continues to occupy the attention of many researchers.

Attitudes are predominantly a matter of affective evaluation. They represent the evaluations (positive or negative) that we associate with diverse entities, for example, individuals, groups, objects, actions and institutions. Attitudes are typically assessed through a direct inquiry procedure in which respondents are essentially asked to indicate their evaluative reaction (like-dislike, and so on) to something or someone. A number of indirect (disguised) measurement procedures have also been developed (Kidder and Campbell 1970), but these are sometimes difficult to apply and have not been widely utilized.

Some theorists contend that attitudes should not be defined solely in affective (or evaluative) terms, suggesting instead that attitudes are normally found in combination with 'related' cognitive and behavioural components. Thus, people who *like* unions will usually hold characteristic beliefs; they may believe, for example, that union activities have often been treated unfairly in the press. In addition, people with pro-union attitudes will often *act* accordingly, by joining a union, or by purchasing union goods in preference to those produced by non-unionized labour. Despite the plausibility of these assertions, however, they have not gone unchallenged; in particular, the relationship between attitudes and behaviour has often proven to be weak or nonexistent.

Rather than defining attitudes such that associated beliefs and behaviours are included as essential components (by definition), contemporary researchers have preferred to focus on the evaluative aspect of attitudes, to judge from the assessment procedures they have developed, and have gone on to study *empirically* the relationship between attitudes and beliefs and the relationship between attitudes and behaviour.

Attitudes and beliefs

A commonsensical approach suggests that our attitudes, pro or con, derive from our beliefs. For example, if we learn that a newly opened store offers excellent service, superior goods and low prices, we are likely to evaluate it positively. Advertising

campaigns are often based on an implicit model of this type; they may attempt to change our beliefs about a product or institution by telling us of the good qualities it possesses, in the hope that this will ultimately influence our attitudes and buying behaviour.

While it is clear that attitudes can be influenced by changes in belief (as outlined above), there is also evidence for the reverse proposition. That is, attitudes may not only be influenced by beliefs, but they may also contribute to the things that we believe (Rosenberg *et al.* 1960). In one study, for example, respondents were led (through direct post-hypnotic suggestion) to accept a new position with respect to foreign aid. Subsequent inquiry indicated that these hypnotically induced attitudes were accompanied by a spontaneous acceptance of new beliefs that had not been mentioned during the induction procedure, beliefs that were supportive of the respondents' new views. Other studies suggest that attitudes may also play a type of filtering role, influencing the extent to which we accept new information that bears on the validity of our attitudes (Lord *et al.* 1979).

Attitudes and behaviour

Attitudes are generally thought to influence behaviour. People who favour a given candidate or political position are expected to vote for that person, or to provide other concrete support (for example, in the form of donations), in contrast to those who hold relatively negative views. Despite the seeming obviousness of this proposition, however, many studies have found only weak, unreliable relations between attitudes and everyday behaviour. Part of the difficulty here derives from the fact that behaviour is often dependent on situational factors that may override the influence of the individual's preferences. Despite the fact that someone holds extremely positive views towards organized religion, she may none the less be unresponsive to requests for financial donations to her church if she has recently lost her job. Similarly, a hotel clerk may override his personal prejudices and politely serve patrons of diverse ethnic origins, if this is what his job requires. On the other hand, there is now persuasive evidence that attitudes may be more substantially associated with everyday actions if we take a broader view of behaviour, tracking the individual's reactions in a wide range of settings rather than just one. For example, although religious attitudes (positive-negative) may be weakly associated with financial contributions to the church, a more clearcut linkage between religious attitudes and religious behaviour may be observed if a composite behavioural index is employed, one that takes account of such matters as weekly religious observance, observance during holiday celebrations, saying Grace before meals, and so on (Fishbein and Ajzen 1974). Attitudes may also be effectively related to overt actions if they are action-oriented and are measured with appropriate specificity. Thus, church donations may be related to people's attitudes toward the concrete act of 'donating to the church', as contrasted with their general attitude towards 'organized religion'.

One of the most firmly established phenomena in contemporary attitude research is the fact that behaviours may have a causal impact on attitudes, rather than simply reflecting the actor's previously held views. This proposition has been supported in a wide range of experiments. In a classic study by Festinger and Carlsmith (1959), some respondents

were led to describe a certain laboratory activity as 'interesting', despite the fact that they actually regarded it as rather dull. People who had enacted this form of counter-attitudinal behaviour for a modest (one-dollar) incentive subsequently rated the dull laboratory task in relatively favourable terms, compared to those who had not been required to produce counter-attitudinal statements. Other researchers have employed a procedure in which a person who was supposed to be 'teaching' something to another seemingly punished the learners with electric shocks whenever they made an error. Subsequent enquiry revealed that people who had served as 'teachers' in this type of situation became increasingly negative to their 'pupils' as a consequence.

The continuing vitality of the attitude construct may derive, in part, from the seemingly universal importance of evaluation (Osgood 1964). We are apparently disposed to respond evaluatively to the people, objects, events and institutions that we encounter. These evaluative (attitudinal) reactions, their origins, correlates and consequences, continue to constitute a fertile domain for academic and applied research.

Austrian School

The Austrian School of Economics is one of the branches of economic thought which grew out of the Marginalist or neo-classical revolution (1870–90). Although basically similar to the teachings stemming from Jevons, Leon Walras and Marshall, the Austrian School's unique ideas were already contained in Menger's relatively slim volume, *Grundsätze der Volkswirtschaftslehre* (1871), thus giving the school its alternative name, the Menger School. Menger was the sole professor of economic theory in the law faculty of Vienna University between 1873 and 1903. Wieser succeeded him in 1904 and held the position until 1922. But from 1904 until 1913, Böhm-Bawerk, too, was an economics professor in the university, which is why the school is also known as the Vienna School.

Menger (1950 [1871]) tried to create a unified theory of prices, encompassing commodity as well as distributional prices. He based this on subjective valuation of the buyers at the moment of purchase, that is, on their direct utility for consumption goods or their indirect utility for productive services. These ideas are similar to other marginalist traditions. But what was unique to Menger's approach was his stress on problems of information in economics (taken up later by Hayek), consequent upon the time structure of production which entails the likelihood of forecasting errors, especially by producers of 'higher order commodities'—those far removed from final demand ('first order commodities'). From this developed the Austrians' concern with both capital and business cycle theory, the two being seen as closely linked (Böhm-Bawerk, Mises, Hayek, Schumpeter). Another unique contribution by Menger was his vision of price formation, with monopolistic pricing or even individual bargains at the fore, and perfect competition only a limiting case. Thus prices are not fully determinate, but subject to bargaining. This approach developed via Morgenstern into the Theory of Games. Menger regarded commodities as typically unhomogeneous; the constant creation of new varieties of final commodities, aside from offering insights into productive possibilities, were to him the most important aspects of development, another idea taken up by Schumpeter. Finally, Menger was the first of many Austrians to be concerned with monetary theory. He saw in money the most marketable commodity, and a medium of reserve held for precautionary reasons, with, consequently, a volatile velocity of circulation.

The best known contributions of Menger's successors are Böhm-Bawerk's (1959) attempts to measure capital in terms of waiting time, and his determinants of 'the' rate of interest. Wieser (1927 [1914]) should be remembered for his notion that prices are, above all, informative, and therefore necessary for all private and social calculations (an idea which is now usually associated with Mises's strictures on the impossibility of efficient socialist economies without market prices). Wieser also propounded the leadership role of the creative entrepreneur, an idea which Schumpeter (1952 [1912]) expanded into his theory of innovation and economic development. Mises (1949) and Hayek created a monetary ('Austrian') theory of the business cycle: investment booms are caused by bouts of bank credit at a market rate of interest below the rate of return on capital, a credit

creation which cannot be prolonged indefinitely without additional saving, so that much new capital formation must be prematurely terminated.

A new Austrian School has developed, particularly in the USA. Taking up the strands of Austrian thought, it stresses the non-static nature of economic processes and the informational uniqueness of entrepreneurial decision taking. It must be noted, however, that both in respect of the full scope of thought and in its personal links, its connection with the now defunct former Austrian School is rather tenuous.

authoritarian and totalitarian systems

Authoritarian systems are political regimes which are characterized by a concentration of political power in the hands of a small group of elites who are not in any institutional sense accountable to the public. Thus, they lack those traits which distinguish liberal democratic orders—in particular, extensive civil liberties, rule of law, inter-party competition and representative government.

There are many forms of authoritarian government. Rule can be by the military or by civilian politicians, and political power can be exercised directly by individuals or through a political party. Perhaps the most important distinction among authoritarian regimes, however, is on the dimensions of despotism and penetration (Mann 1986). Despotism refers to the extent to which political power is capricious and exercised without constraint, and penetration refers to the extent to which the authoritarian state orchestrates everyday life. At one end of this continuum would be one-party dictatorships which none the less have limits on the exercise of political power and violence and which have limits as well on the reach of the state, for example, Mexico. At the other end of the continuum would be totalitarian states, such as we find in its purist form in Stalinist Russia from 1927 to 1953. Totalitarianism features an interlocking and highly centralized party-state directorate which uses terror, detailed organization and ideological indoctrination to control virtually all aspects of social life. In practice, this means control not only over the selection of the political elite and the policy agenda, but also over the society and the economy through control over the media, elaborate socialization of the public, prevention of any organization autonomous from the party-state structure, and, finally, ownership and planning of the economy (Arendt 1951; Friedrich and Brzezinski 1956). Thus, in totalitarianism the familiar boundaries separating politics, economics and society disappear. This allows for a degree of penetration and despotism which is distinctive to this modern form of dictatorship.

The rise of states as forms of political organization were accompanied by the rise of authoritarianism. In this sense, authoritarianism is as old as the state itself, because it was through authoritarian political practices that states began to form (Anderson 1974; Tilly 1975). However, beginning in the eighteenth century in Europe, states began to differentiate themselves in terms of the degree of their accountability to the public. This process—which eventually led in England and France, for example, to the rise of democracy—has produced a spirited set of debates about the rise of democracy versus the consolidation of authoritarian rule in fascist and communist forms (Moore 1967; Rueschemeyer *et al.* 1992).

Debates have also flourished on two other issues. One is why some democracies evolve into authoritarian systems (Collier 1979; Linz and Stepan 1978; Luebbert 1991). The other is why some authoritarian systems collapse and give way to more liberalized political orders (Bunce 1985; Di Palma 1990).

authority

Six distinctions must be drawn in any account of the concept of authority (Friedman 1973; Lukes 1978; Raz 1989).

First, the failure to explain the unity and order of social life and the compliance of subjects solely in terms of coercion and/or rational agreement opens a space for the concept of authority. Authority refers to a distinctive form of compliance in social life. Three accounts exist of the basis of this special compliance. One sees authoritative institutions as reflecting the common beliefs, values, traditions and practices of members of society (Arendt 1963; Parsons 1960); a second sees political authority as offering a co-ordination solution to a Hobbesian state of nature, or a lack of shared values (Hobbes 1651); a third view argues that although social order is imposed by force, it derives its permanence and stability through techniques of legitimation, ideology, hegemony, mobilization of bias, false consensus and so on, which secure the willing compliance of citizens through the manipulation of their beliefs (Lukes 1978; Weber 1978 [1922]).

Second, what is special about the compliance that B renders A which marks off authority from coercion and rational agreement? Coercion secures B's compliance by the use of force or threats; persuasion convinces B by appeal to arguments that an action is in B's interests, is, for example, morally right, or prudent; but B complies with authority when B recognizes A's right to command B in a certain sphere. B voluntarily surrenders the right to make compliance contingent on an evaluation of the content of A's command, and obeys because A's order comes from an appropriate person and falls within the appropriate range. Where authority exists there will be 'rules of recognition' (Hart 1961) or 'marks' by which to identify those eligible to exercise it.

Third, we must also distinguish between *de facto* and *de jure* authority (Peters 1967; Winch 1967). *De facto* authority is evidenced whenever B complies with A in the appropriate manner; *de jure* authority exists where A has a right to B's compliance in a given area which derives from a set of institutional rules. That A has one form of authority in no way entails that A will also have the other.

Fourth, many writers have referred to authority as 'legitimate power'. This may mean either that coercion is exercised by someone with *de jure* authority, although the coerced agent is not responding to A's authority; or that A's orders in fact produce this distinctive form of non-coerced deferential obedience (A thus has *de facto* authority)—this being in sharp contrast to cases where compliance is based on fear.

Fifth, authority is thus a two-tier concept: it refers to a mode of influence and compliance, and to a set of criteria which identify who is to exercise this influence. For this influence to take effect it must be exercised 'within a certain kind of normative arrangement accepted by both parties' (Friedman 1973). This normative arrangement may be a common tradition, practice or set of beliefs (MacIntyre 1967; Winch 1967), or it may be simply a common acknowledgement that some set of rules is required to avoid chaos. B's compliance with A's authority may take two forms: it may be unquestioning (as with Weber's 'charismatic authority') or B may be able to criticize A's command, yet still complies because B recognizes A's right to command, even if B privately disagrees with its content.

Sixth, a further important distinction is that between being *an* authority and being *in* authority. The former concerns matters of belief; the latter concerns A's place in a normative order with recognized positions of *de jure* authority. When A is *an* authority, A is held to have, or successfully claims, special knowledge, insight, expertise, and so on, which justifies B's deference to A's judgement. When A is *in* authority, A claims, and is recognized as occupying, a special institutional role with a co-ordinate sphere of command (as with Weber's legal-rational authority (1978 [1922])). When B complies with A's judgement where A is *an* authority, B's compliance involves belief in the validity of A's judgement; whereas, when A is simply *in* authority, B may disagree yet comply because B recognizes A's *de jure* authority. Traditional and charismatic leaders are authoritative over belief and value; leaders in legal-rational systems are granted authority in certain spheres of action for convenience. Where A is *an* authority, A's influence over B relies on B's continued belief in A's guaranteed judgement. Where A is *in* authority, A relies on B continuing to recognize that A fulfils a valuable co-ordination function. Both systems may face legitimation crises when B no longer believes A, or no longer believes that A successfully co-ordinates. However, both systems may seek to maintain B's belief through a variety of techniques: ideology, hegemony, mobilization of bias, and so on (Habermas 1976 [1973]).

balance of payments

A balance of payments is an accounting record of a country's international transactions with the rest of the world. Foreign currency receipts from the sale of goods and services are called exports and appear as a credit item in what is termed the current account of the balance of payments. Foreign currency payments for purchases of goods and services are called imports and appear as a debit item in the current account. In addition, there are transactions in capital which appear in a separate capital account. Outflows of capital, to finance overseas investment, for example, are treated as debits, and inflows of capital are treated as credits. A deficit on current account may be offset or financed by a surplus on capital account and vice versa. Since the foreign exchange rate is the price of one currency in terms of another, total credits (the supply of foreign exchange) and debits (the demand for foreign exchange) must be equal if the exchange rate is allowed to fluctuate freely to balance the supply of and demand for foreign currency. If the exchange rate is not free to vary, however, deficits or surpluses of foreign currency will arise. Deficits may be financed by government borrowing from international banks and monetary institutions, such as the International Monetary Fund, or by selling gold and foreign currency reserves. Surpluses may be dissipated by accumulating reserves or lending overseas.

The fact that a flexible exchange rate guarantees a balance in the foreign exchange market does not mean that a country is immune from balance of payments difficulties. A country may experience a decline in real income and employment because of the inability

of exports to pay for imports on current account. Such a deficit financed by capital inflows will not preserve jobs, nor will a depreciating currency necessarily guarantee that the current account deficit will be rectified. Neither can a country be indifferent to the international value of its currency. Widely fluctuating exchange rates may adversely affect international trade. A rapidly depreciating currency, which raises the domestic price of imports, can be highly inflationary, which necessitates further depreciation, and so on.

   In considering measures to adjust the balance of payments, therefore, it is highly desirable that countries should focus on the current account if they are concerned with the functioning of the real economy, and (if in deficit) wish to avoid turbulent exchange rates round a declining trend. Three major approaches to balance of payments adjustment have been developed by economists, corresponding to how deficits are viewed. First, the elasticities approach sees deficits as a result of distorted relative prices or uncompetitiveness in trade. Adjustment should work through exchange rate depreciation provided the sum of the price elasticities of demand for imports and exports exceeds unity. Second, the absorption approach views deficits as a result of excessive expenditure relative to domestic output, so that favourable adjustment must imply that expenditure falls relative to output. Third, the monetary approach ascribes deficits to an excess supply of money relative to demand, so that adjustment can be successful only if it raises the demand for money relative to the supply. In many contexts, particularly in developing countries, none of the approaches may be relevant where the problem is one of the characteristics of goods produced and exported, so that the price of balance of payments equilibrium is always slow growth. In this case, there is an argument for structural adjustment through planning and protection. If economic objectives are to be obtained simultaneously, a necessary condition is that the form of adjustment should be related to the initial cause of the disequilibrium.

banking

The word for a bank is recognizably the same in many European languages, and is derived from a word meaning 'bench' or 'counter'. The bench in question appears to have been that of the money-changer at the medieval fairs rather than that of the usurer, and the link of banking with trade between nations and communities has been

maintained. The early banks were often started as a subsidiary business by merchants, shippers, cattle drovers and, more recently, by travel agents. Other banks grew out of the business of the goldsmiths, and some of the earliest were founded for charitable reasons. In the last two centuries, however, banking has become a recognizable trade in its own right, and companies and partnerships have been founded to carry on the specific business of banking.

Each legal system has its own definition of a bank. One common element present in nearly all definitions is the taking of deposits and the making of loans for the profit of the owners of the bank, although in some cases the proviso is made that both the deposits and the loans should be short term. An economist would be more likely to seize on the fact that bankers are able to use a relatively small capital of their own to pass large sums from ultimate lenders to ultimate borrowers, taking a margin on each transaction in the form of higher interest rates for loans than for deposits. Both these approaches credit banks with only one function, the macroeconomic function of intermediation. In reality all banks perform many more functions, while some recognized banks are not particularly active as intermediaries. Many provide payment services, and most act as insurers by giving guarantees on behalf of their customers. Services of this sort could plausibly be regarded as facilitating intermediation, but there are many other services that are purely incidental—investment management, computer services and travel agency are among them. Increasingly important in many countries is the part of the bank's income that comes from fees and commission rather than from the interest margin. Non-interest income had already risen to around 44 per cent of total income for the group of eight large British banks by 1992.

Because the liabilities of banks form a large part of the accepted definitions of the money supply, banks attract government regulation on a scale that is greater than that applying to almost every other sector. This regulation can be divided into two main areas. The first is regulation for the purposes of furthering monetary policy. The other area of regulation covers prudent behaviour of banks in an effort to ensure the safe and efficient functioning of the banking system.

Monetary policy seeks to influence the behaviour of the real economy by changing various financial variables like interest rates, the stock of money, the volume of credit and the direction of credit. Since bank deposits account for a large part of the stock of money, and since bank loans are a very important part of the total volume of credit, it is only natural that banks should be the most important channel for monetary policy measures. The measures that have been imposed on banks include control of their interest rates, primary and secondary requirements on holdings of reserves with the central bank and of government securities, limitation of the amount of credit extended, and control over the direction of credit. Many of these measures built on constraints that the banks had previously observed on their own initiative for prudential reasons.

Banking is a business that depends completely on the confidence of the public, and for the most part banks have always been very careful not to endanger that confidence. After the banking crisis of the early 1930s, the self-regulation that banks had practised for prudential reasons was supplemented in most countries by an elaborate set of prudential regulations and often by detailed supervision; the same intensification of prudential regulation and supervision occurred after the 1974–5 banking crisis. The various

measures adopted are often said to be motivated by a desire to protect the interests of the depositor, but an even more important motive is the need for any government to protect the stability and soundness of the entire financial system. The measures laid down in regulations are designed to prevent bank failures by ensuring that the capital and reserves are adequate to cover all likely risks of loss, and that there are sufficient sources of liquidity to meet cash demands day by day. Many sets of regulations seek to achieve these aims by detailed and rigid balance-sheet ratios, and since 1989 banks of all kinds in most developed countries have been required to observe a minimum ratio devised by bankers from the largest countries meeting at the Bank for International Settlements in Basle. Under this scheme banks must hold capital equal to at least 8 per cent of the total of risk-weighted assets, the weights ranging from zero for government securities up to 100 for normal bank loans.

The agent for carrying out monetary policy is always the central bank, which is in a specially favourable position for influencing financial flows because it is usually the banker to the government, the main domestic banks and the central banks of other countries; it thus stands at the crossroads between the banking system and the private, public and external sectors and can influence the behaviour of all of them to various degrees by its regulations and its market operations.

It has always been thought desirable that the central bank should not be a government department but should have some autonomy. This is sometimes shown, as in the USA and in Italy, by the fact that the central bank is wholly or partly owned by private banks and not by the government; the Bank of England was not nationalized until 1946. In the early 1990s there was considerable pressure for the autonomy to be taken further by granting the central bank complete independence in the formulation and carrying out of monetary policy, subject only to a broad brief from the parliament, to which it would be accountable. Several countries, including France, Italy and Spain, have already granted this independence, following the examples of Germany and the USA.

Prudential regulation and supervision are often carried out by the central bank, as in Britain, Spain and Italy, but many countries, including Germany and the Scandinavian countries, have separate supervisory bodies; the USA has several. The Bank of England has always resisted pressure to give up its supervisory duties. The inevitable bank failures demonstrate that supervision is a poisoned chalice, but the Bank of England claims that the intimate knowledge of individual banks that it yields is essential for carrying out its other duties.

Since the 1960s the banking systems of most developed countries have changed considerably in several directions. The first major trend has been the internationalization of banking. Until the mid-twentieth century, banks conducted most of their international business through correspondent banks in the various countries, but most large and many medium-sized banks now reckon to have branches in all important international financial centres. This move was led by the large banks from the USA, and they and branches of banks from other countries have introduced new techniques and been the catalysts for change in many countries whose banking markets were previously sheltered. Banking has also become internationalized through the establishment of a pool of international bank deposits (the eurodollar market) and through syndicated lending by numbers of large banks to multinational corporations and to governments. During the recession that started

in 1978, the inability of many governments and other borrowers to meet the conditions of loan repayments has been a considerable source of instability, which continued into the recession that started at the end of the 1980s. The heavy provisions that banks had been forced to make against sovereign debt in the first of the two recessions were joined by provisions against domestic loans in the second. The banking systems of developed countries were considerably weakened by these two bouts of provisions against bad loans, and their large customers turned to the capital market for a much higher proportion of their funding needs. Banks have proved very flexible in this situation by themselves acquiring subsidiaries in the securities industry and in insurance and by the switch to non-interest income referred to earlier, but the balance of power in the financial system has moved considerably away from banking to the securities markets and to the institutional investors that are the biggest holders of most types of security.

On the domestic scene, the methods of operation of the international banking market have been adopted in what is termed wholesale banking, in which banks deal with large organizations. The technique is essentially the mobilization of large deposits through an interbank money market to provide funds for loans of up to ten years, often at rates of interest that change every three or six months.

In retail banking, with households and small businesses, the number of personal customers has increased, especially through the payment of wages into bank accounts rather than by cash. Competition has intensified, and savings banks, building societies and co-operative banks are becoming more like the main banks in their powers and kinds of business. The new electronic technology of payments, using the plastic card, will further increase competition, because it will enable institutions without branch networks to compete successfully with those that have branches.

bargaining (economic theories)

Economists are interested in bargaining not only because many transactions are negotiated (as opposed to being entirely determined by market forces) but also because,

conceptually, bargaining is precisely the opposite of the idealized 'perfect competition' among infinitely many traders, in terms of which economists often think about markets. Bargaining situations concern as few as two individuals, who may try to reach agreement on any of a range of transactions which leave them both at least as well off as they could be if they reached no agreement. As early as Edgeworth (1881), it was noted that modelling traders only by their initial endowments and indifference curves, while often adequate to determine a unique competitive equilibrium in a market, would nevertheless leave indeterminate the outcome of bargaining, although it could determine a 'contract curve' in which the outcomes of successful bargaining might be found.

With the advent of game theory, attempts were made to develop theories of bargaining which would predict particular outcomes in the contract curve. John Nash (1950; 1953) initiated two related, influential approaches. In his 1950 paper he proposed a model which predicted an outcome of bargaining based only on information about each bargainer's preferences, as modelled by an expected utility function over the set of feasible agreements and the outcome which would result in case of disagreement. In his 1953 paper, Nash considered a simple model of the strategic choices facing bargainers, and argued that one of the strategic equilibria of this game, which corresponded to the outcome identified in his 1950 paper, was particularly robust.

Nash's approach of analysing bargaining with complementary models—abstract models which focus on outcomes, in the spirit of co-operative game theory, and more detailed strategic models, in the spirit of non-cooperative game theory—has influenced much of game theory. Modern contributions to this tradition include influential work on bargaining by Ariel Rubinstein and Ken Binmore. One direction this work has taken has been to connect bargaining theory with the theory of competitive equilibrium in markets, by examining market models in which agents meet and negotiate transactions, with the option of returning to the market in case of disagreement (see, e.g. Binmore and Dasgupta 1987: Osborne and Rubinstein 1990).

One shortcoming of the classical game theoretic models of bargaining was that they provided little help in understanding disagreements, except to suggest that disagreements resulted primarily from bargainers' mistakes. Incomplete information models help to remedy this, by showing how a positive probability of disagreement may be inescapable at equilibrium, when agents do not know how other agents value all transactions. The underlying intuition is that if you reach an agreement whenever there are gains from trade, then you are not making as much profit on each agreement as you could (see, e.g. the papers in Roth 1985).

Because many game theoretic models of bargaining depend on information difficult to observe in the field (e.g. bargainers' detailed information and preferences over alternatives), these models were long resistant to all but the most indirect empirical tests. However, with the growth of experimental economics, many laboratory experiments were designed to test the predictions of these theories. Although some of their qualitative predictions have received some support, the existing models have performed poorly as point predictors. Most recently, this has led to new (or sometimes renewed) interest in different kinds of theories, having to do with co-ordination and/or learning and adaptive behaviour. (For an account of experimental work see Roth 1995.)

basic needs

The concept of basic needs has played a big part in analysing conditions in poor countries in recent years. In reports produced by international agencies, the term has a long history (see, e.g. Drewnowski and Scott 1966). The term was given particularly wide currency after the International Labour Office's World Employment Conference at Geneva in 1976, where it was formally adopted. Basic needs were said to include two elements:

> Firstly, they include certain minimum requirements of a family for private consumption: adequate food, shelter and clothing, as well as certain household furniture and equipment. Second, they include essential services provided by and for the community at large, such as safe drinking water, sanitation, public transport and health, education and cultural facilities…. The concept of basic needs should be placed within a context of a nation's overall economic and social development. In no circumstances should it be taken to mean merely the minimum necessary for subsistence; it should be placed within a context of national independence, the dignity of individuals and peoples and their freedom to chart their destiny without hindrance.
>
> (ILO 1976:24–5)

The idea has played a prominent part in a succession of national plans (see, e.g. Ghai *et al.* 1979) and in international reports (see, e.g. Brandt 1980; UNESCO 1978).

The term is quite clearly an enlargement of the subsistence concept, the older idea that families could be assessed as to whether their incomes were 'sufficient to obtain the minimum necessaries for the maintenance of merely physical efficiency' (Rowntree 1901). However, the basic needs formulation differs to the extent that it adds a new emphasis on minimum facilities required by local communities. The arbitrariness of the criteria used to select the items on the list is very evident. Moreover, the needs of

populations cannot be defined adequately just by reference to the physical needs of individuals *and* the reference to a few of the more obvious physical provisions and services required by local communities. The exposition of need depends on some assumptions about the functioning and development of societies. The emerging *social* expectations laid upon the citizens of poor countries during periods of development are not adequately acknowledged. The disproportionate poverty and deprivation experienced by tribal groups, ethnic minorities, women, elderly people, children and people with disabilities in such countries is not adequately allowed for in this formulation.

It is important to recognize the function of basic needs in the debates going on about the relationship between the First and Third Worlds. The more that social aspects of need are acknowledged, the more it becomes necessary to accept the relativity of need to the world's and national resources. The more the concept is restricted to physical goods and facilities, the easier it is to argue that economic growth alone, rather than a complex combination of growth, redistribution and reorganization of trading and other institutional relationships, is implied.

behaviour therapy

The movement that has come to be known as behaviour therapy (or behaviour modification) arose shortly after the end of the Second World War, having its origins independently in the USA, Britain and South Africa. In Britain, behaviour therapy developed mainly out of dissatisfaction with the traditional role of the clinical psychologist who worked within a medical model which likened mental disease to bodily disease, except that the former was a disease of the mind rather than the body. There was also dissatisfaction with the psychodynamic approach that viewed patients' symptoms as indicators of some underlying conflict requiring their resolution in-depth analysis, and with the diagnostic (testing) approach resulting in patients being labelled, but without any obvious consequent implications for therapy.

To replace these traditional approaches, it was proposed that psychologists make use of the entire body of knowledge and theory that constituted psychology as a scientific discipline and in which only the psychologist was an expert. In practice, the aim was to be achieved by stressing experimental investigation of the single case (that is, the presenting patient), in which the precise nature of the patient's problem was to be elucidated by systematic investigations. Behaviour therapy was simply the extension of this method to attempts to modify the maladaptive behaviour by similar controlled experimental procedures. In the USA, behaviour therapy developed mainly out of the efforts to apply the principles of operant conditioning to the description and control of human behaviour, especially, in its early stages, the bizarre behaviours of psychotics. In South Africa, the impetus for behaviour therapy came largely from the work of Wolpe (1958). His reciprocal inhibition theory, developed from studies of animal neuroses, underlay the technique of systematic desensitization which was applied to the treatment of phobias with great success, and served more than anything else to bring behaviour therapy to notice as a significant new way of approaching the therapy of maladaptive behaviours.

Between 1950 and 1970 behaviour therapy developed rapidly, its achievements being critically reviewed in three simultaneous publications (Bandura 1969; Franks 1969; Yates 1970). Although Eysenck's definition of behaviour therapy as 'the attempt to alter human behaviour and emotion in a beneficial manner according to the laws of modern learning theory' (Eysenck 1964) has been very widely accepted, Yates (1970) has stressed that

behaviour therapy is a much broader endeavour than Eysenck's definition suggests, since, in principle, the whole body of the knowledge and theory that constitutes psychology is available to the behaviour therapist when dealing with a presenting patient. But for some behaviour therapists, the development of techniques that 'work' is more important than the use of theory and the experimental method, even though the best known technique of all (Wolpe's systematic desensitization) was based on specific theoretical considerations. Justification for a technique-oriented approach, however, stems in part from the demonstration that flooding, a technique directly contradicting Wolpe's theory, appears to be as effective as systematic desensitization in the therapy of phobias. There are few other standard techniques available, one notable successful example being the bell-and-pad method of treating enuresis (bedwetting).

The rapid growth of behaviour therapy has led to its application to a far wider range of problems than could earlier have been envisaged (Yates 1981). In its early stages behaviour therapy was mainly concerned with the investigation of individuals, either alone or in hospital settings. Now it is widely used by professional social workers, in marital therapy, in the design of social communities, in crime prevention and the treatment of criminals, to name but a few areas. The approach has been utilized in the control of littering, energy consumption and refuse disposal; in community aid to the disadvantaged (such as persuading low-income parents to have their children accept dental care). A good indication of the vastly expanded range of behaviour therapy can be gained by perusing successive volumes of the *Journal of Applied Behavior Analysis* (1968+), *Progress in Behavior Modification* (1975+) and the *Annual Review of Behavior Therapy* (1969+).

An important development since the early 1970s has been the attempt to reconcile behaviour therapy with psychodynamic psychotherapy and even to integrate them. Yates (1970) had argued that the two approaches differed so fundamentally in their theories about the genesis and maintenance of abnormalities of behaviour that any reconciliation and inte-gration was impossible. However, such moves had started as early as 1966 and by 1980 had achieved considerable progress (Yates 1983). The strength of the movement is indicated by the appearance of a symposium in *Behavior Therapy* (1982 13: articles by Kendall, Goldfried, Wachtel and Garfield). While admitting the strength of the evidence in favour of a reconciliation and integration, a fundamental difficulty remains, namely the relationship between theory and therapy which makes it difficult, if not impossible, for agreement to be reached on the appropriate therapy for disorders such as enuresis and stuttering; this consequently undermines the apparent integration achieved in relation to more complex disorders such as anxiety (Yates 1983).

Behaviour therapy has become as prominent an approach to the explanation and treatment of disorders of behaviour in the second half of the twentieth century as psychoanalysis was in the first half. There seems no doubt that it has fundamentally and irrevocably altered the framework within which disorders of behaviour are viewed. Its greatest virtue is perhaps its relative open-endedness and therefore its capacity for change and self-correction in the light of empirical evidence. It seems unlikely that it will suffer the fate of many of its predecessors, which became prematurely frozen within a rigid conceptual and methodological framework.

behavioural economics

As the topic of economics is human behaviour in economic affairs, the phrase behavioural economics might be thought redundant. Nevertheless, 'behavioural' must somehow be distinguished from 'neo-classical' economics because the latter generally eschews a detailed empirical study of human choice in favour of deducing the behaviour logically from axioms of perfect rationality. The neo-classical axioms postulate a consistent utility function that the economic actor uses to choose the action which maximizes utility (or, under uncertainty, maximizes expected utility).

Contrast between behavioural and neo-classical theory

Empirically, actual choice behaviour commonly departs widely from the behaviour predicted by the axioms of perfect rationality (see Kahneman *et al.* 1982). Moreover, decision making within business firms is heavily concerned with the discovery of choice

alternatives (e.g. Cyert and March 1993 [1963]), and frequently seeks satisfactory rather than optimal choices; whereas in neo-classical theory, alternatives are generally assumed to be given in advance (but see Stigler 1961), and the goal is the optimum.

In response to these and other major discrepancies between neo-classical assumptions and actual behaviour, neo-classical theorists seldom defend the literal correctness of the axioms, but prefer to argue, first, that departures from the behaviour called for by the axioms are not sufficiently large to have significant consequences for markets or the whole economy, and second, that actors may behave 'as if' they were maximizing utility without actually carrying out the implied calculations. The best known defence of neoclassical theory along these lines is Milton Friedman's (1953).

With respect to the first argument, behavioural economists would reply that changes in behavioural assumptions do, in fact, have major macroeconomic implications: for instance, the differences between Keynesian and neo-classical predictions all stem from departures of the Keynesian model from the assumptions of perfect rationality, Keynes's appeal to 'animal spirits' and to money illusion being two of the most obvious examples. The classical theory also cannot usually arrive at definite predictions about the economic effects of economic policies without making numerous auxiliary assumptions. For example, economic analyses commonly assume that people equate utility with wealth, and that altruism is absent from their economic calculations. But both of these are empirical assumptions, and the evidence indicates that they are false. Current practice in neo-classical economics is highly tolerant of *ad hoc* empirical assumptions of these kinds without requiring empirical support for them.

With respect to the second argument, behavioural economists regard discovering the actual mechanisms underlying economic decisions as a major goal of economic science. Just as molecular biology seeks to explain life processes in terms of chemistry and physics, positive economics seeks to explain the behaviour of firms and individuals in terms of psychological laws. 'As if' assumptions that ignore the computational and knowledge limits of human actors cannot provide a basis for understanding economic choice behaviour.

Hence, on the critical side, behavioural economics is concerned with altering those core and auxiliary assumptions of neo-classical theory that are empirically unsound, and with challenging conclusions drawn from theory that depend on these assumptions. On the positive side, behavioural economics is concerned with building an empirically founded theory of human decision making.

Behavioural theories

Behavioural theory in economics resembles theory in biology more than theory in physics. There are not just a few central phenomena to be explained, but a large number, which interact to produce the behaviour of economic systems. These phenomena are not produced by a few underlying processes, but by numerous interdependent mechanisms. In particular, the theory is much more inductive than deductive, emerging out of empirical investigation. There is a substantial body of theory about human economic behaviour, supported by extensive data.

One part of the behavioural theory explains phenomena that do not depend at all on assumptions of rationality (Simon 1979). For example, the observed average relation of executive salary to size of firm (salaries are proportional to logarithm of firm size) is explicable in terms of the relative constancy of span of control (number of immediate subordinates per executive) and a social norm for the ratio of salaries at adjacent organizational levels. Neo-classical theory had explained this relation only by making strong, *ad hoc* untested assumptions about the distribution of executives by ability. Similarly, the observed logarithmic rank-size distribution of business firms is explicable on the assumption that average growth rates of firms are independent of present size. The neo-classical literature 'explains' this distribution by contrary-to-fact assumptions about the change of cost of production with company size.

Another part of behavioural theory seeks to establish the human motivations that underlie economic decision making, and the circumstances under which particular motives display themselves. Of particular importance is evidence that people sometimes behave altruistically, especially by identifying with particular social groups, ranging from the family and business organizations to ethnic and national groups. As a consequence, the 'I' becomes a 'we', which evaluates alternatives by their consequences for the relevant group instead of the self.

A third part of behavioural theory explains the operation of business firms and the choice between firms and markets. Here organizational identification gives firms a comparative advantage over markets. A second important mechanism accounting for the efficiency of firms is the employment contract, which shifts from employees to employers the management of uncertainty in matters where decisions have much larger consequences for the firm than for the employee. Particular attention is being paid to the information flows, in addition to information about prices, that are required for the conduct of economic affairs. These flows also have strong impact on the choice between organizational and market arrangements. At a more abstract level, and drawing upon both the behavioural and neo-classical viewpoints, the 'new institutional economies' (Williamson 1975) explains the choice between intra-firm and inter-firm arrangements in terms of transaction costs and opportunism (unenforceability of contract conditions).

A fourth part of behavioural theory explains rationality in decision making in the face of people's limited information and limited capabilities for computing consequences ('bounded rationality'). It studies the focus of attention (the small part of the decision context that is actually considered); how problems that reach the agenda are represented and structured; the processes for generating potential problem solutions (design processes); and how design and problem-solving processes are organized in business firms.

New concepts have emerged from this fourth component of the theory and have been investigated empirically, including the respective roles of satisficing (looking for good-enough solutions) and maximizing in making decisions; the formation of aspiration levels that determine what is 'good enough'; the development of individual and organizational expertise by acquiring large knowledge bases and 'indexes' that give access to the knowledge; the routinization of organizational decision making by using the knowledge bases to recognize decision situations and handle them on a rule-governed basis, and

many more.

Research methods

Because of the empirical emphasis of the behavioural theory, much attention has been paid to methods of enquiry. Neo-classical economics, when undertaking empirical verification of its theories, has mostly relied on econometric methods applied to aggregated data. Most often, the data were originally assembled with other purposes than economic analysis in mind.

While not ignoring such data, behavioural economists have sought more direct ways to observe actual decision making in organizations, as well as the behaviour of consumers. Survey research aimed at collecting data about expectations provided much of the early information about departures of actual behaviour from perfect rationality. Techniques have gradually developed for direct observation of decision making in individual business firms; but better methods are needed for aggregating individual case studies into evidence for general theories. Computer simulation of individual and organizational problem solving and decision making has become an important way of stating theories in rigorous and testable form. Finally, there has been a vigorous development of experimental economics, especially the laboratory study of markets. All of these improved and new techniques facilitate progress in our understanding of human decision making, and, as a consequence, our understanding of human bounded rationality in the operation of business firms, markets and the economy.

behaviourism

Behaviourism is mainly a twentieth-century orientation within the discipline of psychology in the USA. The behavioural approach emphasizes the objective study of the relationships between environmental manipulations and human and animal behaviour change, usually in laboratory or relatively controlled institutional settings. Emerging as a discrete movement just prior to the First World War, behaviourism represented a vigorous rejection of psychology defined as the introspective study of the human mind and consciousness. Early behaviourists eschewed the structuralism of Wundt and Titchener, the functional mentalism of James, Dewey, Angell and Carr, and the relativism and phenomenology of Gestalt psychology.

John B.Watson is credited with declaring behaviourism a new movement in 1913, but the foundations of the development extend back to the ancient Greeks and include empiricism, elementism, associationism, objectivism and naturalism. The direct antecedents of behaviourism during the late nineteenth and early twentieth centuries were the studies of animal behaviour and the functional orientation inspired by Darwin's theory of evolution; the conditioning research of Russian physiologists Ivan Pavlov and Vladimir Bekhterev emphasizing stimulus substitution in the context of reflexive behaviour; and the puzzle box studies of US psychologist Edward Thorndike concerned with the effects of the consequences of behaviour on response frequency. The two predominant and often competing theoretical-procedural models of conditioning research have been classical conditioning derived from the work of Pavlov and Bekhterev, and Skinner's operant conditioning.

While it is generally claimed that behaviourism as a distinct school ceased to exist by the 1950s, behaviourism as a general orientation has gone through the following overlapping periods: classical behaviourism (1900–25), represented by the work of Thorndike and Watson; neo-behaviourism (1920s–40s), an exciting time when the theories of Clark Hull, Edward Tolman, Edwin Guthrie and Burrhus F.Skinner competed for pre-eminence; Hullian behaviourism (1940–50s), when Hull's complex hypothetico-deductive behaviour theory appeared most promising; Skinnerian behaviourism (1960s-mid–1970s), during which time operant conditioning techniques, emphasizing the control of behaviour implicit in the consequences of behaviour, afforded the most powerful methodologies; and, finally, cognitive behaviourism (1975-present) when the limits of a purely Skinnerian approach to behaviour change became increasingly apparent, and cognitive perspectives, such as social learning theories, seemed necessary to account for behaviour change.

A behavioural orientation has been central to twentieth-century psychology in the USA primarily because of a strong faith in laboratory research and experimental methodologies; an interest in studying the process of learning; a preference for quantitative information; the elimination from the discipline of ambiguous concepts and investigations of complex and therefore difficult to describe private (subjective)

experiences; and, since the late 1950s, a very conservative approach to theory building.

While each of the major behavioural programmes from Thorndike's to Skinner's failed to provide a comprehensive account of behaviour change, the behavioural orientation has led to the development of behaviour-control methodologies with useful application in most areas of psychology. In addition, the movement has inspired precision and accountability in psychological enquiry.

Behavioural methodologies have, of course, been employed by psychologists in countries other than the USA, particularly those with strong scientific traditions such as Britain and Japan. Behavioural assumptions have also influenced other social sciences, especially sociology and political science. But because laboratory animal research is central to the behavioural orientation, behaviourism as a major movement developed only in psychology.

Bentham, Jeremy (1748–1832)

Jeremy Bentham was undoubtedly one of the most important and influential figures in the development of modern social science. His numerous writings are major contributions to the development of philosophy, law, government, economics, social administration and public policy, and many have become classic texts in these fields. To these subjects he brought an analytical precision and careful attention to detail which, especially in matters of legal organization and jurisprudence, had not been attempted since Aristotle, and he transformed in method and substance the way these subjects were conceived. He combined a critical rationalism and empiricism with a vision of reform and, latterly, radical reform, which gave unity and direction to what became Philosophic Radicalism. Although he was not the first philosopher to use the greatest happiness principle as the standard of right and wrong, he is rightly remembered as the founder of modern utilitarianism. Many of Bentham's writings were never published in his lifetime or were completed by various editors. The new edition of the *Collected Works* (1968-in progress) will replace in approximately sixty-five volumes the inadequate *Works of Jeremy Bentham* (1838–43), edited by John Bowring, and will reveal for the first time the full extent and scope of Bentham's work.

Bentham is best known for some of his earliest writings. *An Introduction to the Principles of Morals and Legislation* (printed in 1780 and published in 1789) and *Of Laws in General* (not published until 1945) are important texts in legal philosophy and,

together with his critique of William Blackstone's *Commentaries on the Laws of England* in the *Comment on the Commentaries* (published first in 1928) and *A Fragment on Government* (1776), represent major landmarks in the development of jurisprudence. The *Introduction to the Principles of Morals and Legislation* was also intended to serve as an introduction to a penal code, which was an important part of a lifelong ambition, never fully realized, of constructing a complete code of laws (latterly called the *Pannomion*). At this time Bentham also turned to economic questions which were to occupy him in various forms throughout his life. His first publication was the *Defence of Usury* (1787), a critique of Adam Smith's treatment of this subject in *The Wealth of Nations.*

From the outset of his career, Bentham was devoted to reform and especially to the reform of legal institutions. His attitude towards fundamental political reform developed more slowly. Although at the time of the French Revolution he was not part of the radical movement in England, he wrote numerous manuscripts in support of democratic institutions in France. He eventually reacted strongly against the excesses of the revolution, but earlier contacts, largely developed through Lord Lansdowne, and the publication of his *Draught of a New Plan for the Organisation of the Judicial Establishment of France,* led to his being made an honorary citizen of France. One important development of this period was his friendship with Etienne Dumont, the Swiss reformer and scholar, whose French versions of Bentham's works, especially the *Traités de législation, civile et pénale* (1802), were read throughout Europe and Latin America and earned for Bentham a considerable international reputation. Following the French Revolution much of Bentham's practical energies were devoted, in conjunction with his brother Samuel, to establishing model prisons, called Panopticons, in various countries. His main effort in England failed, and this failure, though ultimately compensated by the government, was one factor leading him to take up the cause of radical political reform. The influence of James Mill was perhaps the most important factor (there were many) in his 'conversion' to radicalism in 1809–10, and the publication of *A Plan of Parliamentary Reform* in 1817 launched the Philosophic Radicals in their quest for parliamentary reform. In the 1820s, though now in his seventies, Bentham resumed the task of codification and the construction of the *Pannomion* in response to requests from governments and disciples in Spain, Portugal, Greece and Latin America. In his massive, unfinished *Constitutional Code* (1822–), he set forth a theory of representative democracy which was a grand synthesis of many of his ideas and a classic of liberal political thought.

Boas, Franz (1858–1942)

Franz Boas, born in Germany in 1858, naturalized US citizen in 1892, unquestionably dominated both the intellectual paradigm and institutional development of twentieth-century American anthropology until the Second World War, presiding over the emergence of anthropology as a professional discipline based on the concept of culture, and establishing a subdisciplinary scope including cultural, physical and linguistic anthropology as well as prehistoric archaeology.

In spite of his focus on professionalism in science, Boas himself was trained in (psycho)physics in his native Germany, thereby coming into contact with the folk psychology of Wundt and the anthropology of Bastian (European folk cultures) and Virchow (anthropometry). Boas's dissertation at the University of Kiel in 1881 on the colour of sea water led to concern with the inherent subjectivity of observer perception. His work in geography with Fischer initially supported environmental determinism, but his expedition to the Eskimo of Baffin Land in 1882–3 led to a more flexible argument stressing the interaction of culture and environment.

Boas settled permanently in North America only in 1887, recognizing greater opportunities there for an ambitious young Jewish scholar. In the ensuing years, he was crucially involved in the development of American anthropology in all of its early major centres. The institutional framework for the emerging Boasian anthropology was usually collaboration between a university, ensuring the academic training of professional anthropologists, and a museum to sponsor field research and publication. Boas himself settled in New York, teaching at Columbia from 1896 until 1936. He had previously served as Honorary Philologist of the Bureau of American Ethnology, which dominated Washington and government anthropology. Through F.W.Putnam of Harvard, he organized anthropology at the Chicago World's Fair of 1892 and acquired ties to archaeological work centring at Harvard. Boas's own students established programmes elsewhere, particularly Kroeber at Berkeley, Speck at Pennsylvania, and Sapir in Ottawa.

By about 1920, Boasian anthropology was firmly established as the dominant paradigm of the North American discipline.

Boas's theoretical position, often characterized as historical particularism, claimed that unilinear evolution was an inadequate model for the known diversity of human cultures. Human nature was defined as variable and learned tradition. Although he was extremely interested in particular historical developments, Boas argued that progress did not necessarily follow a fixed sequence, nor was it always unidirectional from simple to complex. He further parted from evolutionary theorists like E.B.Tylor in his contention that cultural learning is basically unconscious rather than rational. Boas produced particular ethnographic examples to argue the limits of theoretical generalization in anthropology, indeed in social science generally. 'Laws' comparable to those of the natural sciences were possible in principle though usually premature in practice. The ultimate generalizations of anthropology would be psychological (1911b), but Boas's own studies rarely transcended the prior level of ethnographic description. Later students, especially Margaret Mead and Benedict, elaborated these ideas in what came to be called culture and personality.

Particular histories could not be reconstructed in detail for societies without written records. In contrast, Boas stressed the historical dimensions of synchronically observable, particular cultural phenomena. For example, distribution was the primary reconstructive method to trace the diffusion (borrowing) of folklore motifs and combinations on the Northwest Coast. Elements in a single culture had diverse sources rather than a single common origin. Boas applied this same argument to linguistic work, assuming that language was a part of culture. His scepticism about distant genetic relationships of American Indian languages was consistent with his lack of training in Indo-European philology, and brought him into frequent disagreement with his former student Edward Sapir, whose linguistic work was far more sophisticated.

On the other hand, Boas made important contributions to linguistics, being the first to establish the theoretical independence of race, language and culture as classificatory variables for human diversity (1911 a). He broke with the Indo-European tradition in insisting on the 'inner form' (Steinthal) of each language in its grammatical patterning, developing new analytic categories appropriate to American Indian languages.

Boas insisted on the importance of firsthand fieldwork in living cultures, and he returned again and again to the Kwakiutl and other Northwest Coast tribes. He trained native informants to record their own cultures, and collected native language texts for folklore as well as linguistics. He was particularly concerned to record the symbolic culture of these tribes, focusing on art, mythology, religion and language, and was influential in the development of the disciplines of folklore and linguistics as well as anthropology.

Boas's own research spanned the scope of anthropology in its North American definition. In archaeology, he pioneered in Mexico and the Southwest in developing research programmes to reconstruct the history of particular cultures. In physical anthropology, he demonstrated that the head-form of descendants of immigrants can change in a single generation, thereby illustrating the essential variability and plasticity of the human form. He further developed important statistical methods for human growth studies, using longitudinal studies and family-line variation to show the role of

environment in modifying heredity. Moreover, Boas was dedicated to the idea that anthropology had practical consequences for society generally, arguing, particularly in response to events in Nazi Germany at the end of his life, for the essential equality of races (defined in terms of statistical variability) and the validity of each cultural pattern.

Boas is, then, more than any other individual, responsible for the characteristic form which the discipline of anthropology has taken in North America. During his long career, he and several successive generations of students stood for a particular scope, method and theory, applied largely to the study of the American Indians. The increasing diversity of North American anthropology since The Second World War still has Boasian roots.

body

Since the early 1970s the human body has become a vivid presence in the human sciences and interdisciplinary cultural studies. Feminist theory, literary criticism, history, comparative religion, philosophy, sociology, psychology and anthropology are all implicated in the move towards the body. It has been suggested that this widespread interest in the body may be due to the current historical moment in which 'we are undergoing fundamental changes in how our bodies are organized and experienced' such that we are seeing 'the end of one kind of body and the beginning of another kind of body' (Martin 1992:121).

Recent scholarship (Bynum 1989; Frank, 1991) appears to support this claim. The body has been typically assumed, by scholarly and popular thought alike, to be a fixed,

material entity subject to the empirical rules of biological science, and characterized by unchangeable inner necessities. The new body beginning to be identified can no longer be considered a brute fact of nature. A chorus of critical statements has declared that 'the body has a history' in that it behaves in new ways at particular historical moments, that neither our personal nor social bodies are natural because they exist only within the self-creating process of human labour, and that as the existential ground of culture the body is characterized by an essential indeterminacy and flux. With biology no longer a monolithic objectivity, the body is transformed from object to agent.

Others argue that the human body can no longer be considered a 'bounded entity' due to the destabilizing impact of social processes of commodification, fragmentation, and the semiotic barrage of images of body parts (Kroker and Kroker, 1987). In the milieu of late capitalism and consumer culture, the body/ self is primarily a performing-self of appearance, display, and impression management. Fixed life-cycle categories are blurred, and the goals of bodily self-care have changed from spiritual salvation, to enhanced health, and finally to a marketable self. The asceticism of inner body discipline is no longer incompatible with outer body hedonism and social mobility, but has become a means towards them.

The contemporary cultural transformation of the body is also observable in the problematizing of the boundaries of corporeality itself. These include the boundaries between the physical and non-physical, between animal and human, between animal/human and machine or automaton, and between human and gods or deities. Yet another inescapable transformation of the contemporary body is being wrought by the incredible proliferation of violence: ethnic violence, sexual violence, self-destructive violence, domestic violence, and gang violence. From the dissolution of self in torture and the denaturing of the body in situations of chronic political violence, from unarticulated bodily resistance to hegemonic oppression among the impoverished and again to the madness of 'ethnic cleansing' and rape as political weapons, the body is the threatened vehicle of human being and dignity.

Across these transformations, several general approaches to the body can be identified in current literature. A premise of much writing is an 'analytic body' that invites discrete focus on perception, practice, parts, processes or products. Other literature concentrates on the 'topical body', that is, an understanding of the body in relation to specific domains of cultural activity: the body and health, the body and political domination, the body and trauma, the body and religion, the body and gender, the body and self, the body and emotion, the body and technology are examples. Finally, there is the 'multiple body', with the number of bodies dependent on how many of its aspects one cares to recognize. Douglas (1973) called attention to the 'two bodies', referring to the social and physical aspects of the body. Scheper-Hughes and Lock (1987) give us 'three bodies', including the individual body, social body, and body politic. O'Neill (1985) ups the ante to 'five bodies': the world's body, the social body, the body politic, the consumer body, and the medical or medicalized body.

To greater or lesser degrees these approaches study the *body* and its transformations while taking *embodiment* for granted. Emphasis on embodiment problematizes conceptual dualities between mind and body, pre-objective and objectified, subject and object, culture and biology, mental and material, culture and practice, gender and sex.

There is among champions of the body in contemporary theorizing a tendency to vilify what is usually called Cartesian dualism as a kind of moral abjection. Yet Descartes in part introduced the doctrine as a methodological distinction and a way to free scientific thought from subjection to theology and strict institutional supervision by the Church. The philosopher is doubtless not entirely to blame for the ontologization of the distinction, and the way it has become embedded in our thinking (cf. Leder 1990).

The possibility that the body might be understood as a seat of subjectivity is one source of challenge to theories of culture in which mind/subject/culture are placed in contrast to body/object/biology. Much theorizing is in fact heir to the Cartesian legacy in that it privileges the mind/subject/culture set in the form of representation, whether cast in terms of rules and principles by social anthropology and sociology, signs and symbols by semiotics, text and discourse by literary studies, or knowledge and models by cognitive science. In such accounts the body is a creature of representation, as in the work of Foucault (1979; 1986), whose primary concern is to establish the discursive conditions of possibility for the body as object of domination. In contrast, the body can be comprehended as a function of being-in-the-world, as in the work of Merleau-Ponty (1962), for whom embodiment is the existential condition of possibility for culture and self. If indeed the body is in a critical historical moment, the corresponding theoretical moment is the tension between representation and being-in-the-world.

Braudel, Fernand (1902–85)

Fernand Braudel was one of the most influential historians of the twentieth century. The third of the founding fathers of the so-called Annales School of French historians, he followed the lead of such pre-Second World War historians as Lucien Fèbvre and Marc Bloch in seeking to revitalize the study of history in the light of the methods and concerns of the social sciences. However, Braudel went considerably further along this path than his predecessors, developing an entirely new concept of, and approach to, historical studies. In a more systematic way than his precursors, Braudel sought to emancipate history from its traditional division into political, economic and cultural history and to achieve a 'total' history of society. The objective was to integrate all aspects of humankind's past, placing the chief emphasis on the changing environment and lifestyle of the common person and of society as a whole. Inevitably, the new approach involved a marked de-emphasizing and distancing from the political and constitutional history, which had always been the central preoccupation of historians and which Braudel and his followers term *'histoire événementielle'*.

Braudel's most famous and important work, on the Mediterranean world in the age of Philip II, was first published in 1949 and was greeted with widespread and eventually almost universal acclaim. A revised and considerably expanded second edition was published in 1966. In this vast undertaking, Braudel transcended all political and cultural borders, as he did in all historical practice and procedure. He sought to reveal the immense scope and implications of the decline of Mediterranean society in the sixteenth century, achieving a majestic and often elegant synthesis of economic, demographic, cultural and political data and interpretation. It was by no means Braudel's intention to disregard political phenomena; rather he wished to tackle these in a new way, within the context of long- and medium-term socioeconomic trends. Thus one of his principal objectives was to throw new light on the shift in the policy concerns of Philip II of Spain away from the Mediterranean and towards the Atlantic, a change in the direction of

Spanish policy making which dates from the 1580s.

Basic to Braudel's approach was his novel categorization of history into simultaneous processes proceeding on different levels at quite different speeds. He envisaged these various trends as taking place on three main levels and, on occasion, compared the processes of historical change to an edifice consisting of three storeys. On the lowest level, he placed the slow, long-term changes in humankind's agrarian, maritime and demographic environment. On the middle level, Braudel placed the medium-term economic and cultural shifts which take place over one or two centuries rather than millennia. Finally, on his uppermost storey, he located all short-term fluctuations and 'events' in the traditional sense.

This novel approach to history is further developed in Braudel's second major work, an ambitious trilogy entitled *Civilisation matérielle et capitalisme* (1967–79) (English trans., 1973–82 *Civilization and Capitalism*), which deals with the evolution of the world economy and of society generally from the end of the Middle Ages to the industrial revolution. Despite Braudel's insistence on material factors as the determinants of social change, and his readiness to borrow concepts from Marx, including the term capitalism which figures prominently in his later work, Braudel's system, like the work of the Annales School more generally, is in essence quite outside the Marxist tradition in that it allocates no central role to class conflict. In the view of some scholars, certain weaknesses evident in the earlier work are much more pronounced in the later study. A less secure grasp of detail, frequent errors both of fact and interpretation of data and, generally, much less convincing evaluations detract considerably from the value of the later work. Certain historians now also see serious defects in Braudel's overall approach, running through his entire *œuvre* which, besides the two major works, includes a number of noteworthy short books and essays. In particular it is felt that Braudel's method of handling the interaction between socioeconomic and political history is unconvincing and unsatisfactory. Thus, his radical de-emphasizing of political and military power, and the impact of 'events' on socioeconomic development, gives rise in his writing to numerous, often major, distortions.

The influence of Braudel's ideas and the extent to which they have been adopted as the modern approach to historical studies varies from country to country, but is pervasive in several European and many Latin American countries as well as in North America. It has been repeatedly asserted that he was 'indisputably the greatest of living historians', but it must also be said that a tendency towards uncritical adulation of his work has become fashionable in many quarters on both sides of the Atlantic. Some history departments in universities, and a number of collaborative historical research projects and publications, have professed Braudel and his approach as the guiding principle directing their studies.

bureaucracy

Agreement as to when and how the word bureaucracy was invented is widespread and precise. 'The late M. de Gornay…' notes Baron de Grimm, the French philosopher, in a letter dated 1 July 1764, 'sometimes used to…invent a fourth or fifth form of government under the heading of *bureaucratic.*' Within a very short time, the physiocrat economist's word entered the international language of politics: the Italian *burocrazia,* the German *Bureaukratie* (later *Bürokratie*), and the English 'bureaucracy' (Albrow 1970).

Agreement about what the word means, however, could hardly be *less* widespread or precise. In political debate, writes Martin Albrow, '"bureaucracy" has become a term of strong emotive overtones and elusive connotations'. Social scientists have been no more precise. 'Sometimes "bureaucracy" seems to mean administrative efficiency, at other times the opposite. It may appear as simple as a synonym for civil service, or it may be as complex as an idea summing up the specific features of modern organizational structure. It may refer to a body of officials, or to the routines of office administration' (Albrow 1970).

This confusion may be more apparent than real. From the plethora of definitions, two stand out: bureaucracy as rule by officials, and bureaucracy as a particular form of organization. Even these meanings, though distinct, are not unrelated.

Rule by officials was Vincent de Gornay's intention when, in the style of 'democracy' and 'aristocracy', he attached the Greek suffix for rule to the French word 'bureau', which already included 'a place where officials work' among its definitions. It also was the meaning of Harold Laski when he defined bureaucracy in the 1930 *Encyclopaedia of the Social Sciences* as 'A system of government the control of which is so completely in the hands of officials that their power jeopardizes the liberties of ordinary citizens', and of Harold Lasswell and Abraham Kaplan (1950), who defined it in *Power and Society* as 'the form of rule in which the élite is composed of officials'.

Twentieth-century heirs to de Gornay's definition of bureaucracy have characteristically shared his observations on 'bureaumania'—the spread of bureaucracy as well. They regard rule by officials to be the most prevalent form of government in modern society. Some have traced this rise to officials' organized concentration of expert knowledge. Others, such as Robert Michels (1962 [1911]), have explained it in terms of the imperatives of large-scale organization itself: 'Who says organization, say oligarchy.'

Most modern authors of the de Gornay school have also inherited his displeasure with what he called the 'illness' of bureaucracy. Yet their shared distress belies the polarity of their diagnoses. Sometimes bureaucracy is looked upon as 'intolerably meddlesome', 'a demanding giant', 'an oppressive foreign power', and sometimes as 'timid and indecisive', 'flabby, overpaid, and lazy'. The same critics often seem to regard bureaucracy as both aggressive and passive. Laski, for example, having identified bureaucracy as a form of rule that 'jeopardizes the liberties of ordinary citizens', adds in the next sentence that: 'The characteristics of such a regime are a passion for routine in administration, the sacrifice of flexibility to rule, delay in the making of decisions and a refusal to embark upon experiment.'

In all cases, however, officials tend to be judged by subscribers to this first definition as the real power in any political system in which the ranks of officialdom are large. It was this view that Max Weber (Gerth and Mills 1946) challenged in the early part of the twentieth century, with arguments that set the stage for the development of bureaucracy's second definition, as a particular form of organization.

To Weber, those who equated large numbers of officials with rule by officials sometimes confused appearance and reality. They saw official orders given and obeyed, and assumed from this that officials were wielding independent power. In truth, Weber argued, orders were more likely obeyed because their recipients believed that it was right to obey. Not power *per se,* but 'authority'—power cloaked with legitimacy—was at play. In modern society, such authority characteristically was 'legal' rather than 'charismatic' or 'traditional' in nature: officials' orders were considered legitimate when officials were seen to be acting in accordance with their duties as defined by a written code of laws, including statutes, administrative regulations, and court precedents.

As Weber conceived it, bureaucracy was the form of organization best suited to the exercise of legal authority. If legal authority calls for 'a government of laws and not of men', bureaucracy may be thought of as 'an organization of positions and not of people'. Bureaucratic organizations consist of offices whose powers and duties are clearly defined, whose activities are recorded in writing and retained in files, and whose arrangement in relation to one another is hierarchic. Offices are filled on the basis of 'merit', as measured by diplomas, examinations, or other professional qualifications. Officeholders occupy, but in no sense own, their positions or the powers, duties, and other resources that go with them. Their personal relationships with the organization are defined by contracts that specify salary and career structure.

'Rule by officials' and 'a particular form of organization' are very different understandings of bureaucracy. But they also are related: as this history has shown, one definition was formed in reaction to the other. There may even be grounds for reconciling, if not fusing, the two.

Weber, for example, seemed most provoked by the connotations that were usually

attached to the 'rule by officials' definition—the easy assumption that wherever officials proliferated, they governed. He was right in seeing that this assumption was often made, but one would be wrong in thinking it necessarily must be made. One can think of bureaucracy as a form of government without assuming that it is the most prevalent form of government.

Conversely, it is not uncommon for those who define bureaucracy in organizational terms to be concerned about rule by officials, either as dangerously efficient (a 'demanding giant') or as hopelessly inefficient ('flabby, overpaid, and lazy'). For Weber's part, he warned in one of his most widely remembered passages of the potential power of bureaucracy at its most efficient:

> Under normal conditions, the power position of a fully developed bureaucracy is always overtowering. The 'political master' finds himself in the position of the 'dilettante' who stands opposite the 'expert', facing the trained official who stands within the management of administration. This holds whether the 'master' whom the bureaucracy serves is a 'people'…or a parliament…a popularly elected president, a hereditary and 'absolute' or a 'constitutional' monarch.
>
> (Gerth and Mills 1946)

Other social scientists who basically accept Weber's definition of bureaucracy direct their concerns about bureaucratic power to the inefficiency of such organizations. Robert Merton (1952), for example, notes the danger, inherent in any rules-bound organization, that the rules will become ends in themselves, blinding officials to the organization's service functions and making them resistant to change. In the same spirit, Michel Crazier (1964) describes bureaucracy as 'an organization that cannot correct its behaviour by learning from its errors'.

Burke, Edmund (1729–97)

Edmund Burke, the British statesman and political theorist, was born in Dublin in 1729. He came to London in 1750 and soon acquired a reputation as a philosopher and man of letters. In 1765 he was elected to the House of Commons, acting as party secretary and chief man of ideas to the Whig connection led by the Marquis of Rockingham. He wrote voluminously, and the eloquence he brought to expressing a high-minded but by no means unrealistic view of political possibilities has never been surpassed. He could bring out the universal element in the most parochial of issues.

Burke's enduring importance in articulating a political tendency is particularly evident in the *Reflections on the Revolution in France* (1790) and subsequent late works in which he defended his criticism of the Revolution against fellow Whigs who had welcomed it as an act of liberation from an odious Bourbon absolutism. Attacked as one who had betrayed the cause of liberty, Burke agreed (in the *Appeal from the Old to the New Whigs*) that consistency was the highest virtue in politics, but proceeded to theorize its complex nature. In supporting the American colonists, he argued, he was in no way committed to support every movement which raised the banner of liberty, for in his view the Americans 'had taken up arms from one motive only; that is, our attempting to tax them without their consent' (Burke 1855, *Appeal,* vol. 3). Real political consistency must take account of circumstances, and cannot be deduced from principles. And it was in terms of the contrast between historical concreteness and abstract principle that Burke interpreted the challenge posed by the revolutionaries in France.

The revolutionaries were, Burke argued, amateur politicians attempting to solve the complex problems of French society with a set of theories or what he called 'metaphysic rights'. They believed that an ideal rational constitution, in which a republic guaranteed the rights of humankind, was suitable for all societies. This belief constituted a revelation which stigmatized most existing beliefs as prejudice and superstition, and all existing forms of government as corrupt and unjust. On Burke's historical understanding of the specificity of different societies, the beliefs and practices of any society revealed their character; indeed, properly understood, they revealed a kind of rationality much more profound than the propositional fantasies of revolutionaries. To condemn what whole societies had long believed as merely mistaken was in the highest degree superficial. Society is a delicate fabric of sentiments and understandings which would be irreparably damaged if subjected to the butchery of abstract ideas. Burke judged that, as the revolutionaries discovered that the people were not behaving according to the rationalist prescriptions, they would have increasing recourse to violence and terror. At the end of every prospect would be found a gallows. He predicted that the outcome would be a military dictatorship.

Burke's genius lay in breaking up the conventional antitheses through which politics was then understood. He had never been, he wrote, 'a friend or an enemy to republics or to monarchies in the abstract' (Burke 1855, *Appeal,* vol. 3), and this refusal to take sides

on an abstractly specified principle became a dominant strain in conservatism. The real clue to wisdom politics lay not at the level of high principle but of low and humble circumstance. This was the level of actual human experience, and, at this level, there was not a great deal that governments could achieve, and most of what they could was to prevent evils rather than promote goods. No stranger to paradox, Burke insisted that one of the most important of the rights of humankind is the right to be restrained by suitable laws. Again, Burke was prepared to agree that society was indeed a contract, but he instantly qualified this conventional judgement by insisting that it was a contract of a quite sublime kind, linking the living, the dead and those yet to be born. It is in these hesitations and qualifications of conventional wisdom to which he was impelled by the excitements of his time that Burke's contribution to political understanding lies.

More philosophically, Burke adapted to political use the empiricist doctrine that the passions, especially as entrenched in and shaped by social institutions, are closer to reality than the speculations of philosophers, and especially of *philosophes.* His defence of prejudice threw down a gauntlet to the superficial rationalism of his opponents, and has sometimes been seen as expressing an irrationalism endemic to conservative thought. It is, however, an argument about the relations between reason and passion similar to that of Hegel, though in a quite different idiom.

Burke's political judgement is a conservative modification of the English political tradition and covers many areas. On the nature of representation, for example, he argued that the House of Commons was not a congress of ambassadors from the constituencies. His defence of the place of parties in British politics contributed to the acceptance and development of party government, however limited in intention it may have been (Brewer 1971). In the indictment of Warren Hastings, he stressed the trusteeship of power and property which was never far from his thoughts. But in all his political writings, Burke wrote to the occasion, and it is perilous to generalize about him too far. His personal ambitions required manoeuvring in the complex world of late eighteenth-century politics which have led some writers (e.g. Namier 1929; Young 1943) to regard him as little more than a silver-tongued opportunist. This is to do less than justice to the suggestiveness of his prose and the momentousness of the occasions to which he so brilliantly responded.

business concentration

Business seller concentration refers to the extent to which sales in a market, or economy, are concentrated in the hands of a few large firms. At the level of an individual market or industry, *market concentration* is thus an (imperfect) indicator of the *degree of oligopoly,* and measures thereof are widely used by industrial economists in empirical tests of oligopoly theory. The most popular operational measure is the *concentration ratio,* which records the share of industry size (usually sales, but sometimes employment or value added) accounted for by the k largest firms (where, usually, $k=3$ or 4 or 5). Its popularity derives more from its regular publication in Production Census reports than from a belief in its desirable properties (either economic or statistical). The multitude of other concentration measures include the Hirschman-Herfindahl index, which is the sum of squared market shares of all firms in the industry, the Hannah-Kay index, a generalization of the former, and various statistical inequality measures borrowed from the study of personal income distribution. While there is general agreement that a respectable measure of concentration should be inversely related to the number of sellers and positively related to the magnitude of size inequalities, these criteria are satisfied by a large number of the alternative indexes, and there is no consensus on what is the ideal measure.

   Evidence on market concentration is readily available for most western economies, and although differences in methods of data collection and definitions make most international comparisons hazardous, three broad facts are indisputable. First, the pattern of concentration is similar within most countries, with high concentration prevalent in consumer good and capital-intensive industries. Second, typical levels of market concentration are higher in smaller economies. Third, in-depth studies of the UK and the USA suggest that, on average, the five firm ratio may be as much as fourteen points higher in the UK. Studies of trends over time show a steady and pronounced increase in the UK from 1935 to 1968, with a levelling off in the 1970s. In the USA, market concentration has remained fairly constant since the Second World War.

   Theories on the causes of concentration include the technology and entry barrier explanation (emanating from the Structure-Conduct-Performance paradigm), and a range of stochastic models based on Gibrat's Law of Proportionate Effect. The latter are largely (statistically) successful in accounting for the characteristic positive skew observed in most firm size distributions and for the steady increase in concentration ('spontaneous drift'). They do not, however, provide a true economic understanding of the forces at

work. Empirically, mergers have also been identified as a major source of concentration increases.

A*ggregate concentration* is often measured as the share in GDP, or aggregate manufacturing of the top 100 corporations. In the UK this rose dramatically from 16 per cent in 1909 to 40 per cent in 1968 and then remained constant up to 1980.

business cycles

Business cycles are recurring cycles of economic events involving a period of more rapid than normal or average growth (the *expansionary phase*) and culminating in a peak, followed by a phase of slower than average growth (a *recession*), or a period of negative growth (a *depression*) culminating in a trough. In the post-war literature, business cycles are normally assumed to be forty to sixty months in duration, and they are distinguished from various longer cycles that have been discussed in the economics literature, such as the six-to eight-year Major trade cycle, the fifteen- to twenty-five-year Kuznets or building cycle, and the fifty- to sixty-year Kondratieff wave.

Business cycles have commonly been viewed as evolving around a long-term growth trend, especially in the post-war period, and this has typically led to a divorce of 'business cycle theory', which attempts to explain the fluctuations around the trend, from 'growth theory', which attempts to explain the trend growth itself In the 1970s, interest in long waves revived, and an alternative view is that business cycles are short-term fluctuations in economic activity around longer cycles or waves. In this case, business cycles are analysed as growth cycles, with alternating rapid growth expansionary phases and slower growth contractionary phases (or recessions) during the upswing of the long wave; while during the downswing of the long wave they will involve periods of positive growth in the expansionary phase followed by periods of zero or negative growth in the contractionary phase (or depression).

There has been some debate about whether business cycles are systematic economic fluctuations, or whether they are instead purely random fluctuations in economic activity. It is certainly true that business cycles are not regular, in the sense of a sine wave with constant period and amplitude. But the weight of evidence, largely due to the accumulated studies produced through the National Bureau of Economic Research, indicates that business cycles are sufficiently uniform to warrant serious study.

Business cycle modelling in the post-war period has usually adopted the approach, suggested by the work of Frisch (1966 [1933]) and Slutsky (1937 [1927]), of regarding the economic system as fundamentally stable but being bombarded by a series of shocks or unexpected events. Economists commonly attempted to devise a 'propagation model' of the economy capable of converting shocks, generated by an impulse model, into a cycle. Using this strategy, many different models have been devised; these vary according to the degree of stability assumed in the 'propagation model', the form of the series of shocks emanating from the 'impulse model', and the sources of the shocks and sectors of the economy described by the propagation model. The various models have commonly involved linear stochastic second order equation systems. The linearity assumption serves both to simplify analysis and to allow an easy separation of business cycle and growth theory, because growth can be represented by a linear or log linear trend. There have been exceptions to this general modelling strategy that have used nonlinear equa-tion systems capable of generating—in the absence of shocks—self-sustaining 'limit cycles'. These can be stable and self-repeating even in the face of shocks, which merely impart some additional irregularity. Since the late 1970s catastrophe theory and bifurcation theory have been used to develop models of the cycle in which nonlinear discontinuities play a key role. Chaos theory, which can explain the seeming irregularity of business cycles using simple nonlinearities, has also been employed. Such contributions have been relatively rare but may become more common as economists increasingly familiarize themselves with nonlinear techniques of mathematical and statistical analysis. The possibility of modelling the business cycle as a limit cycle, as an alternative to the Frisch-Slutsky approach, raises the general question of whether the business cycle is something that would die out in the absence of shocks, or whether it is endogenous to the economic system.

The nonlinear models have also commonly treated business cycles and growth theory as separable. There is, however, an alternative view, which is that business cycles and growth should be explained together, and that a theory of dynamic economic development is required. This view is most frequently associated with the work of Schumpeter (1989).

In 1975 papers by Nordhaus (1975) and Lucas (1975) discussing the political and the equilibrium theories of the business cycle had a major impact. The political theory of the business cycle argues that business cycles are in fact electoral economic cycles which result from governments manipulating the economy in order to win elections. This contrasts the broad Keynesian consensus view of the mid-1960s that governments, through anti-cyclical demand management policies, had on the whole been successful in reducing the amplitude of the cycle, although it was accepted that at times they may have aggravated it because of the problems involved in allowing for the lag in the effect of policy interventions. The equilibrium theory of the business cycle assumes that economic agents are endowed with 'rational expectations' but must make decisions based on inadequate information about whether price changes are purely inflationary, so that no real response is required, or whether they indicate a profitable opportunity. In models based on this theory, systematic anti-cyclical monetary policy can have no effect, and the only contribution the government can make is to reduce the shocks to the economy by pursuing a systematic monetary policy. The equilibrium theory of the business cycle

contrasts with most other theories, which view business cycles as being fundamentally a disequilibrium phenomenon. Although the political and equilibrium theories have many contrasting features, they both raise questions concerning the appropriate treatment of the government in business cycle models. The Keynesian consensus view was that the government could be treated exogenously. In contrast, the political and equilibrium theories of the business cycle indicate that the government should be treated endogenously in business cycle models. A promising new approach to business cycle modelling is the game theoretic analysis of government policy making.

Both the political and equilibrium theories of the business cycle have their origins in much earlier literature. The evidence in their support is rather less than conclusive. Nevertheless, these modern theories revived interest in the nature and causes of business cycles, and spawned a large literature on 'real business cycles', which are equilibrium cycles driven by real, rather than monetary, shocks. They also provoked a reconsideration of the appropriate policy responses to business cycles, based on the analysis of policy credibility and reputation, which led to support for central bank independence.

business studies

The term business studies is a loose generic title for several related aspects of enterprises and their environments, foremost among these being administration and management, accounting, finance and banking, international relations, marketing, and personnel and industrial relations. There is considerable disagreement, however, on the extent to which scholastic, managerial or professional values should predominate in the framing of the curriculum and in research and teaching objectives.

It is usual to trace modern ideas on business studies to formative developments in the USA, where the Wharton School of Finance and Commerce was the first of 20 schools of business administration and commerce to be founded between 1881 and 1910. But it was particularly in the next two decades, when a further 180 schools were established, that the distinc-tive US style of business education, with a high degree of abstraction and a quantitative approach to the solution of problems, became firmly rooted (Rose 1970). Management education developed much later in Europe, originally under the tutelage of practitioners from the USA. Indeed, in Britain, it was not until 1947 that the first major centre, the Administrative Staff College at Henley, was inaugurated. There are now several leading European institutes for business and management studies. In both Europe and Japan, there have been active attempts to develop programmes which are distinctive from the original North American model, a change which has been facilitated by the considerable interest in business studies in Third World nations and by the rigorous analytical techniques which have latterly evolved in the USA.

The precise causes of the expansion of business education are open to some doubt, although processes of rationalization in modern societies and the rapid growth in numbers of managerial personnel have been signal influences. Further favourable trends have been increased international competition and investment, major technical changes, a larger scale and greater complexity of modern enterprises and a facilitative role of governments.

However, opinion differs on whether business studies should become an empirical social science or whether, to the contrary, it should be founded on a series of prescriptive values (what should be accomplished) and ideas (what can be achieved) in actual employing organizations. A particular problem of internal coherence in business education also stems from the varied subject backgrounds of research workers and teachers, a situation which has militated against an adequate interdisciplinary synthesis.

In principle, the theoretical linkages between the main areas of business studies are examined in business policy, although this has in practice become a highly specialized area dealing primarily with the intertemporal concept of strategy. In substantive terms, organizational behaviour is the most obvious branch of study that connects the disparate approaches within the business field. Nevertheless, its excessive reliance on contingency theory (which implies that whether a particular organizational form is effective depends on the nature of the environmental context) has proved to be an encumbrance, since challenges to this approach have ensured that there is no longer a generally accepted

model for conceptualizing business behaviour.

A further critical issue in business studies is the extent to which, regardless of cultural, socioeconomic or political conditions, common administrative practices are appropriate on a worldwide scale. The earliest perspectives tended to assume a considerable uniformity, the various strands being combined in the 'industrial society' thesis in which a basic 'logic of industrialism' was seen to impel all modern economies towards similar organizational structures and modes of administration (Kerr *et al.* 1960). This complemented the earlier work on classical organization theory, which postulated universal traits of business management, and on studies of bureaucracy, which arrived at similar conclusions. In this approach, too, a key assumption was that there had been a divorce of ownership from control in the business enterprise that, in turn, had ensured the convergence of decision-making processes between societies with ostensibly irreconcilable political ideologies and economic systems.

More recently, however, the 'culturalist' thesis has emerged as a check-weight to these universalist approaches. This assumes great diversity in business behaviour and ideology occasioned either by variations in the 'task' environment (community, government, consumer, employee, supplier, distributor, shareholder) or, more especially, in the 'social' environment (cultural, legal, political, social). Above all, it emphasizes that each new generation internalizes an enduring strain of culture through its process of socialization, with people in different countries learning their own language, concepts and systems of values. Moreover, such deep-rooted cultural forces are continually reasserted in the way people relate to one another and ensure that organizational structures which are not consonant with culturally derived expectations will remain purely formal.

Divergence in business organization and practice can also stem from temporal as well as spatial differences between societies. Indeed, 'late development' would appear to enhance a mode of industrialization quite distinct from the earliest western models, with the state being more predominant at the expense of a *laissez-faire* ideology, educational institutions preceding manufacturing, more substantial technical and organizational 'leaps', human relations and personnel management techniques being more advanced, and large-scale enterprises being deliberately constructed as a spearhead for economic advancement (Dore 1973). In this respect, too, the choices of strategic elites are as important as the constraints of environment and organizational structure in determining which types of business conduct become ascendant in any given society.

Since the Second World War, business studies have been influenced by notions of 'human resource management' (Blyton and Turnbull 1992). The issue here is whether business managers have wider moral obligations, beyond seeking to enhance profitability and efficiency. 'External social responsibility' is particularly relevant to marketing policies. Various ethical questions are raised by the strategies and techniques for promoting different types of goods and services (Baird *et al.* 1990). 'Internal social responsibility' has to do with employee welfare and satisfaction, and human relations in the enterprise. More broadly, there has been a major expansion of research and teaching in the fields of personnel management and industrial relations (Schuler and Huber 1993).

The structure of business studies courses often shows evidence of a tension between professional and managerial approaches. Another unresolved issue is the extent to which

business studies should concentrate on the development of empirical social science, perhaps at the expense of consultancy work.

C

cannibalism

Cannibalism, as the customary consumption of human flesh in some other time or place, is a worldwide and time-honoured assumption. This pervasive, and in many ways appealing, characterization of others has also found its place in contemporary anthropology, which has tended to accept uncritically all reports of cannibalism in other cultures as ethnographic fact. This propensity has led to the development of a variety of categories for the conceptualization of the pattern and motivation for the purported behaviour. These have included the recognition of endocannibalism (eating one's own kind) as opposed to exocannibalism (eating outsiders), and ritual in contrast to gustatory or nutritional cannibalism. Uncondoned survival cannibalism, under conditions of extreme privation, has also been noted. Yet, despite the uncounted allusions and the elaborate typologies, there is reason to treat any particular report of the practice with caution, and the entire intellectual complex with some scepticism.

This estimation is warranted for a number of reasons. Depending on time or place, written accounts of alleged cannibalism entered the historical record long after the cessation of the purported custom—often after the obliteration of the culture itself and the

decimation of its population. Moreover, reporters were representatives of the very society that was then engaged in the subjugation and exploitation of the people in question. Those responsible for our contemporary impressions rarely took an unbiased view of the traditional culture, and at best relied upon informants who claimed that 'others', such as the nobility or priesthood, engaged in such reprehensible practices. Consequently, rather than reliably documenting a custom, between the early sixteenth and late nineteenth centuries the allegation of cannibalism in western literature often merely legitimized the conquest of foreign cultures by expansionist European states.

These suspect conditions could have been rectified by modern anthropologists actually resident among presumed cannibals in the remoter regions of the world. However, contemporary reports continue to be secondhand; indeed, no anthropologist has ever provided an account of cannibalism based on observation. While reasonable explanations are offered for these circumstances, for example, that the practice has been discontinued or is now hidden, the overall pattern continues to be one of circumstantial rather than direct evidence.

Thus, is it reasonable to assume that cannibalism ever occurred? The answer is yes, but neither as often nor in the context usually assumed. There is as indicated survival cannibalism, but also an antisocial or criminal variety and sometimes subcultural cannibalism practised by a deviant segment of the population (see Parry 1982). In rare instances, 'inversion' cannibalism has also occurred. The first three types are sporadically noted in every part of the world, where they are frowned upon by the majority. The final instance, of which there are a few accounts, involves rituals in which members of a society are constrained to act for the moment in ways prohibited under ordinary moral circumstances (Poole 1983). Such occasions of inversion underscore the basic rules of society by intentional violations but should not be construed as custom in the general sense. There is a simplistic and unwarranted tendency to label non-western societies with such restricted practices of any aforementioned type as cannibalistic. This suggests that the portrayal of others as man-eaters, rather than the deed itself, is the pervasive human trait.

capital, credit and money markets

Production requires capital to be laid down in advance; capitalist economies have developed markets to allow the division of function between the person undertaking the production, the 'entrepreneur', and the ultimate owner of capital. The modern capital market, as this nexus of markets is called, extends across frontiers and embraces a wide variety of contracts, from debt and credit through preferential shares to ordinary equity (i.e. shared ownership). Investors of capital are able through diversification, between different types of projects and contracts, to obtain the most favourable combination of risk and return. The entrepreneur is able to tap into sources of funds that similarly offer the best combination of risk and cost.

In addition to the primary markets in debt and equity, 'derivative' markets have developed that allow investors and entrepreneurs to adjust their portfolios of assets and liabilities to a quite precise mix. This mix is defined by the events that would trigger costs and returns: through options and futures one may protect one's position against a particular event such as the outcome of an election while being exposed to, say, the economy's growth rate. (An option is a contract for someone to pay or receive a sum contingent on an event, while a future is a purchase or sale of a primary instrument made for a future date.)

The modern theory of finance suggests that in capital markets free from controls the multitude of people buying and selling will drive the expected return on (or, seen from the other side, the cost of) investment to a risk-free rate plus a risk-premium that should reflect (besides the average investor's dislike of risk or 'risk-aversion') 'systematic' risk, by which is meant the contribution to the overall risk on a portfolio made by holding this asset. This contribution will depend on the correlation between returns on this asset and on other assets, which is taken advantage of by diversification. Since this correlation should be reasonably stable, this risk-premium ought to be stable too and invariant to the amounts of the asset being traded, provided these are small relative to the market as a whole. Furthermore if people make proper use of available information (rational expectations) then the expected return should change only when new information arrives in the market.

This theory is that of 'efficient markets', efficient in the sense that information is being reflected appropriately in market prices (and hence in expected returns): this also implies that the capital markets allocate capital in the most economical way between uses, so that government intervention could not (using the same information) improve matters. At an international level it implies extremely high capital mobility between countries: a country's entrepreneurs or government will be able to raise as much capital as they can profitably employ at a cost that will reflect the general international cost of capital adjusted for their particular risk-premium.

This smoothly functioning world of capital may seem too good to be true; certainly in empirical testing the results have been mixed. Statistical tests over past data generally

reject the hypothesis of strict efficiency (such rejection could be partly explained by variability of risk-premiums though this should normally be modest). Nevertheless, it has also proved hard to make above-normal returns by investment strategies other than those which used information unavailable to the market: this suggests a fair degree of efficiency. There is clearly a tension between the exploitation of information driving above-normal returns to zero and there being sufficient above-normal returns available to motivate the research into an analysis of information that makes such exploitation possible: it may well be, therefore, that the markets are 'nearly efficient'—with just enough inefficiency to enable analysts to make a living. This state of affairs would justify using the theory as a working approximation.

So far we have made no mention of money. Indeed it would be quite possible to envisage this world of capital markets functioning without money. If everyone had a balance in a gigantic clearing system, whose unit was some amount of a consumer good or combination of several (a 'basket'), then money would be unnecessary. However, it is a fact that many goods are paid for by money by most people and most goods are paid for by money by some people. The reason is to do with the cost of doing business (transactions cost): clearing systems are good value typically for large transactions by people with some security to offer, money is typically good value for small transactions and for people with no security. The costs of both sorts of exchange technology also depend on how intensively and widely they are used, the size of their network—rather like a telephone system.

Notice that money and capital markets are quite separate things. Money is a means of exchange (of anything), one way of permitting exchange in any set of markets; while capital markets trade capital and could use various means of exchange to carry out this trade, including a clearing system or money. (Cash could also be used as part of the portfolio, as a store of value, but being non-interest-bearing it would make better sense to hold a savings deposit in a bank.)

However, once money exists as the means of exchange it acquires potential importance for the functioning of the whole economy. The usual institutional set-up will be one in which money (cash) is used for a limited set of goods and clearing systems (such as credit cards and cheques) for the rest, with cash as their unit of account. By this is meant that to close a balance in these systems one must produce cash. Therefore ultimately cash might have to be used; of course in practice cash may well not be used. For example in bank accounts cash is virtually never used to close them; rather they continue in credit or overdraft. With credit card balances, again cash is rarely used: instead bank account balances are transferred to settle them.

How does money affect the economy and capital markets in such a set-up? Money, being the unit of account, now implies a price level: the amount of money needed to pay for a basket of goods. Also the rate of interest is expressed in money; other capital contracts may not be (equity gives part-ownership of a company, for example) but their prices in the market are, and are related as above to the risk-free rate of interest. It follows that the government (or the central bank if it has the authority) can either fix the quantity of money (cash which it prints), or the price level (through a conversion rule for example as under the early gold standard, where it offers to buy goods, or print money, if their price level falls below a certain level and vice versa), or the rate of interest.

Given that people want cash in order to carry out transactions, printing money will give them more than they initially require. The oldest of theories, the quantity theory, views this requirement as related to the volume of transactions, the price level, and the period over which money turns over (basically the gap between wage payments). The latter should be sensitive to the rate of interest because non-interest-yielding cash creates an incentive to economise by more frequent payment. Hence these different policies of government are in certain conditions equivalent: printing money creates an excess supply of money which must induce higher demand by lowering the rate of interest; lowering the rate of interest increases the demand and this can only be met by printing more money. These two equivalent policies then raise spending on capital and consumption so that, assuming that the economy is fully employed and cannot produce extra quantities, the price level will be driven up. Direct action by government to raise the price level would equivalently have raised the price level, and this would have raised demand for money which would have required extra to be printed.

This way of thinking—in which full employment was assumed to be normal—dominated economics before the First World War. Money was seen as the way to control the price level. It was considered fairly immaterial whether the control was carried out by direct printing control, or indirectly, by fixing interest rates or pegging the price level. After the First World War the Great Depression focused minds (particularly that of J.M.Keynes) on how monetary contraction could depress output and employment rather than only prices: the answer seems to be that most contract prices for goods and labour are written in money terms and are renegotiated at intervals, so that prices change only slowly. Hence sharp unexpected changes in monetary conditions (whether the gold parity, interest rates, or money printed) could have their first effect on output. When this happens these three monetary policy interventions will have different effects: it will depend on the shocks that may hit the economy, whether policies that stabilize money supply, the price level, or interest rates are preferable. The recurring debate over whether exchange rates should be fixed or flexible can be seen in this light. (The evidence tends to suggest that a modern economy facing a wide variety of demand and supply shocks will be better served by flexible rates that permit competitiveness to adjust quickly and also allow interest rates to vary flexibly to maintain employment stability; experience within the European Exchange Rate Mechanism has reinforced the point.) Modern thought (following the work of monetarists such as Milton Friedman and Karl Brunner) accepts such ideas for the short run while maintaining the classical position for the long run, when monetary policy should have its sole impact on prices (or if it is persistently expansionary, on inflation in which case it will also affect interest rates as capital providers protect their returns against it). However, there is no general agreement on the precise short-run mechanisms.

Some monetary theorists have stressed that credit availability rather than cost (interest rates) is the channel by which monetary policy works. However, while this appears superficially attractive from experiences of 'credit crunches', such episodes (for example in 1980 in the USA) tend to occur when controls on credit or other capital markets are introduced. When capital markets are free of controls it is hard to see why availability of finance should be limited given the wide variety of instruments through which capital can be made available.

capital consumption

Understanding capital consumption (that is, the using up of fixed capital) must be based on an understanding of the distinction between fixed capital and circulating capital. In this context, the term capital refers to tangible assets (i.e. as excluding financial assets). Items of circulating capital have only a once-for-all (or 'once-over') use in the process of production; items of fixed capital have a continuing and repeated use in the process of production. A dressmaker has a stock of cloth and a sewing machine: the cloth has a once-for-all use in the process of dressmaking; the sewing machine can be used repeatedly. The cloth is *circulating capital;* the sewing machine is *fixed capital.* The universal feature of items of fixed capital (apart from land) is that, for more than one reason, they have finite working lifetimes and will eventually have to be replaced (as the cloth has immediately to be replaced) if the production process is to continue.

Suppose the working lifetime of a sewing machine is ten years: at the beginning of Year 1 the dressmaker starts business with a (new) sewing machine valued at $ 1,000 and at the end of Year 10 the sewing machine is worth nothing (assuming it has no residual scrap-metal value). In order to continue in business, the dressmaker has then to spend $1,000 on replacing the sewing machine (abstracting from inflation—a very significant proviso). Now, if over the years the dressmaker has not gathered in from all the customers an aggregate amount of $1,000, then the effect is that those customers have had the free gift of the services of the sewing machine. Therefore, customers should be charged for the use of fixed capital. Suppose the dressmaker makes 200 dresses a year; over ten years 2,000 dresses will have been made and customers should be charged 50 cents per dress, reckoned as: $ 1,000 (original capital cost of sewing machine) *divided by* 2,000 (dresses) *equals* $0.50 per dress. The 50 cents is the charge for (fixed) capital

consumption per dress, and is analogous to the charge made for the cloth used. The price charged must include the cost of capital consumption per dress.

However, most enterprises do not proceed in this direct way to incorporate capital consumption into the price(s) of the item(s) they produce. Instead, the same result may be achieved by making an overall deduction of annual capital consumption from annual gross income (income gross of—including—capital consumption). The dressmaker may deduct from gross income an *annual* charge for capital consumption, reckoned as: $1,000 (original capital cost of sewing machine) *divided by* 10 (years—the lifetime of the sewing machine) *equals* $100 per annum.

If 'income' is to be taxed, then net income rather than gross income is the appropriate tax-base. Hence tax authorities have regulations concerning the deduction of (annual) capital consumption, otherwise known as depreciation provisions.

There are various methods of calculating the flow of depreciation provisions. The formula just given is known as the 'straight-line' method, because it gives a linear decline in the depreciated value of the fixed capital stock and a linear increase in the cumulated depreciation provisions (that is, there is a constant annual charge for depreciation), as follows: beginning Year 1, $1,000 capital, $0 cumulated depreciation provisions; end Year 1, $900 depreciated value of capital, $100 cumulated depreciation provisions; end Year 2, $800 depreciated value of capital, $200 cumulated depreciation provisions; and so on until end Year 10, $0 depreciated value of capital, $1,000 cumulated depreciation provisions. Together the sum of depreciated capital and cumulated depreciation provisions always equal $1,000 and so 'maintains' capital (i.e. wealth) intact.

This arithmetic example illustrates the definitions that: 'Depreciation is the measure of the wearing out, consumption or other loss of value of a fixed asset' (Accounting Standards 1982); or that capital consumption is the fall in the value of fixed capital between two accounting dates; or that charging depreciation provisions is a method of allocating the (original) cost of a long-lived asset to the time periods in which the asset is 'used up'. It also illustrates how the purpose of charging capital consumption against gross income to arrive at net (true) profit is to prevent an enterprise from 'living off its capital': 'A provision for depreciation reduces profit by an amount which might otherwise have been seen as available for distribution as a dividend' (Pizzey 1980). It is not essential that the depreciation provisions be re-invested in the same item: it is quite in order for the dressmaker to invest, in an ongoing way, the depreciation provisions in, say, a knitting machine. What is essential is that sufficient capital equipment for production purposes continues to be available.

capital punishment

Capital punishment, accompanied by torture, is widely applied and taken for granted in most pre-industrial societies, past and present (see, e.g. Diamond 1971). In modern industrial societies there has been a tendency towards decreasing severity of criminal punishments, and, especially, towards decreasing use of the death penalty (Gorecki 1983). This pattern has been particularly marked in European history, although the total abolition of capital punishment became a publicly articulated demand only after the Enlightenment. Most liberal democracies do not now have the death penalty, but many authoritarian societies readily apply capital punishment.

Among the democracies, the USA is the most conspicuous exception. Following a protracted struggle, the American abolitionists resorted, in the 1960s, to judicial review: they petitioned Federal courts rather than lawmakers to ban the penalty on the ground of the constitutional prohibition of 'cruel and unusual punishments'. Abolitionist scholars supplied the Supreme Court with relevant sociolegal empirical data which some Justices cited in their opinions. However, the abolitionists lost the struggle in the wake of a crucial Supreme Court decision of 1976; following that decision, the majority of the states in the USA continue to punish the most abominable cases of murder by death. This development was precipitated by the increasing public anger against high rates of violent crime in the USA.

The arguments of both abolitionists and retentionists are many and hotly debated. The most forcefully stressed retentionist plea is utilitarian (or, strictly speaking, teleological): capital punishment is claimed to deter wrongdoing even better than lifelong confinement. There are further utilitarian contentions as well: that capital punishment constitutes the only secure incapacitation, and that it increases respect for criminal law. Non-utilitarian retentionists believe in the ultimate retributive value of capital punishment as the only 'just desert' for the most abhorrent crimes. In rejoinder, the abolitionists question the superior deterrent value of the death penalty. Furthermore, they stress the sanctity of human life and immorality of the state killing anyone. They argue that the penalty brutalizes society, and endangers the innocent, because judicial errors do occur. Moreover, they claim that the penalty is arbitrarily imposed, and often tainted by prejudice, especially if the perpetrator is black and the victim white (Baldus *et al.* 1990). They also feel that the suffering of convicts who are led to execution and of those who wait on death row is appalling. Believers in the re-education of wrongdoers rather than in retribution as the basic goal of criminal justice complain that execution not only is vindictive but also precludes rehabilitation.

The logical status and empirical validity of these arguments vary The non-utilitarian arguments constitute moral axioms, like any ultimate ethical norms. The utilitarian arguments are questionable on purely empirical grounds. This is particularly true of the deterrence idea, which has stimulated a wealth of statistical inquiries. Despite their increasing refinement—especially by Ehrlich (1975) and his opponents—the enquiries

have been inconclusive; we do not know and may never learn whether capital punishment deters most effectively. But while the impact of the death penalty on the functioning of criminal justice remains unproved and uncertain, the question as to whether we send criminals to their death presents a moral dilemma of utmost importance. That is why interest in the issue remains intense, particularly in the USA.

Since the defeat of the abolitionists in 1976, the US crime rates have risen dramatically. This generated such continuing growth of punitive attitudes that politicians hardly dare to appear 'soft on crime', and often use (and abuse) advocacy of the gallows for political purposes. Since the 1980s, the consistently retentionist Supreme Court stopped utilizing sociolegal empirical studies, which were designed to test the factual assertions underlying the normative views of individual Justices (Acker 1993; Ellsworth 1988; Zimring 1993). In this climate the abolitionists, active and influential in the late 1970s, have lost most of their clout.

Will the USA join the abolitionist club of the most advanced societies? This will probably happen if and when violent crime is brought under control by a conjunction of new social and legal policies. This would have to include the implementation of a viable family and educational policy, guaranteeing adequate upbringing and training for all of America's children and adolescents, and, on the legal front, an over-haul of the criminal justice system. With crime under control, and the pervasive anger and fear of crime disappearing, the tendency towards declining harshness of criminal punishments cannot but start working again, and the day of the abolitionists will probably come. But, for constitutional reasons, it should come through legislative process rather than the action of the Supreme Court. Since legislatures constitute an audience obviously more open to scholarly expertise than the judicial branch, empirical data relevant to the struggle for and against abolition will once more be granted attention.

capital theory

Capital's role in the technological specification of production and as a source of income called interest or profit encompasses theories of production and accumulation and theories of value and distribution. The subject has perplexed economists because capital produces a return which keeps capital intact and yields an interest or profit which is thus permanent, while consumption goods produce a unique return (utility) equal to cost and are destroyed in use.

The pre-industrial classical economists thought of capital as stocks of food and provisions advanced to labour; it was the accumulation of stocks making possible the division of labour which was of importance. This position is reflected in J.S.Mill's (1886 [1848]) statement that to 'speak of the "productive powers of capital"…is not literally correct. The only productive powers are those of labour and natural agents.' Capital was at best an intermediate good determined by technology and thus subject to exogenous or 'natural' laws, rather than human or economic 'laws'.

By Marx's time, factory-labour working with fixed machinery had become widespread, and he was impressed by the increase in the ratio of 'dead' labour, which had gone into producing the machines, to the living labour which operated them. Marx's idea of a 'mode of production' made capital a social, rather than a purely technological, relation; it was not the machinery, but the operation of the laws of value and distribution under capitalism that produced revolutionary implications. This integration of production and distribution challenged Mills's separation and clearly raised the question of the justification for profit or interest as a permanent return to capital.

Jevons was among the first to note the importance of the time that labour was accumulated in stock. Böhm-Bawerk's Austrian theory of capital built on time as a justification for interest in answer to Marx. The Austrians considered human and natural powers as the original productive factors, but 'time', which allowed more 'roundabout' production processes using intermediate inputs, was also productive. Longer average periods of production would produce greater output, but in decreasing proportion. It was the capitalists' ability to wait for the greater product of longer processes, and the workers' haste to consume, which explained the former's profit.

Clark extended Ricardo's classical theory of differential rent of land to physical capital goods, considering diminishing returns to be a 'natural law' of production. In Clark's explanation it is the capital goods themselves which are considered productive, their return equal to their marginal product. Determination of capital's 'marginal' contribution requires that it be 'fixed' while the amount of labour employed varies, but 'transmutable' into the appropriate technical form when different quantities are used with a 'fixed' quantity of labour.

L.Walras shifted emphasis from physical capital goods to their services as the 'productive' inputs and the return to owning the goods themselves which can then be analysed as the exchange and valuation of the permanent net revenues they produce.

Wicksell (1934) was critical of Walras, rejected 'time' as a productive factor, and was sceptical of the application of marginal theory to aggregate capital, for the 'margin' of the capital stock could not be clearly defined. The problem was in the fact that 'land and labour are measured each in terms of their own technical unit' while 'capital…is reckoned as a sum of exchange value…each particular capital good is measured by a unit extraneous to itself', which meant that the value of capital, equal in equilibrium to its costs of production, could not be used to define the quantity used to calculate its marginal return because 'these costs of production include capital and interest. …We should therefore be arguing in a circle' (Wicksell 1934). Wicksell's argument recalls the original classical view of capital as an intermediate good, a produced means of production, rather than an 'original' productive factor.

Fisher made a sharp distinction between the flow of income and the capital stock that produced it; since discounting future income converts one into the other, the key to the problem is in the role of individual preferences of present over future consumption, or the 'rate of time preference' in determining the rate of interest. The greater the preference for present goods, the higher the rate of time discount and the lower the present value of future goods represented by the stock of capital.

Keynes's *General Theory* assumption of a fixed stock of capital and the absence of a clear theory of distribution left open the analysis of capital and the determination of the rate of interest or profit to complement the theory. Neoclassical theorists (based in Cambridge, USA) added a simplified version of Clark's theory via an aggregate production function relating homogeneous output to the 'productive' factors: labour and aggregate capital, in which the 'quantity' of capital would be negatively associated with its price, the rate of interest. This preserved the negative relation between price and quantity of traditional demand theory. Cambridge (UK) economists rejected capital as a productive factor, arguing that the value of the heterogeneously produced means of production comprising 'aggregate capital' could not be measured independently of its price, which was a determinant of the value used to identify its quantity. These theoretical disputes came to be known as the 'Cambridge Controversies' in capital theory.

A crucial role was played in these debates by Sraffa's (1960) theory of prices, which furnished formal proof of Wicksell's criticisms by demonstrating that changes in the rate of interest (or profit) in an interdependent system could affect the prices of the goods making up the means of production in such a way that the sum of their values representing the aggregate 'quantity' of capital might rise or fall, or even take on the same value at two different rates of interest. These demonstrations came to be known as 'capital reversal' and 'reswitching' and clearly demonstrated that the negative relation between the quantity of aggregate capital and the rate of interest had no general application. Such criticism does not apply to the analysis of individual capital goods, although a general equilibrium in which the rate of return is uniform requires the comparison of competing rates of return and thus ratios of profits to the value of the capital goods that produce them. Modern theorists agree only on the inappropriateness of aggregate capital concepts.

capitalism

The term capitalism relates to a particular system of socioeconomic organization (generally contrasted with feudalism and socialism), the nature of which is more often defined implicitly than explicitly. In common with other value-loaded concepts of political controversy, its definition—whether implicit or explicit—shows a chameleon-like tendency to vary with the ideological bias of the user. Even when treated as a historical category and precisely defined for the purpose of objective analysis, the definition adopted is often associated with a distinctive view of the temporal sequence and character of historical development. Thus historians such as Sombart (1915), Weber (1930 [1922]) and Tawney (1926), who were concerned to relate changes in economic organization to shifts in religious and ethical attitudes, found the essence of capitalism in the acquisitive spirit of profit-making enterprise and focused on developments occurring in the sixteenth, seventeenth and early eighteenth centuries. Probably a majority of historians have seen capitalism as reaching its fullest development in the course of the Industrial Revolution and have treated the earlier period as part of a long transition between feudalism and capitalism. Marxist historians have identified a series of stages in the evolution of capitalism—for example, merchant capitalism, agrarian capitalism, industrial capitalism and state capitalism—and much of the debate on origins and progress has hinged on differing views of the significance, timing and characteristics of each stage. Thus Wallerstein (1979), who adopts a world-economy perspective, locates its origins in the agrarian capitalism that characterized Europe of the sixteenth, seventeenth and eighteenth centuries; while Tribe (1981), who also takes agrarian capitalism as the original mode of capitalist production, sees the essence of capitalism in a national economy where production is separated from consumption and is co-ordinated

according to the profitability of enterprises operating in competition with each other.

Whatever the historical or polemical objective of writers, however, their definition is likely to be strongly influenced by Karl Marx (1867–94), who was the first to attempt a systematic analysis of the 'economic law of motion' of capitalist society and from whom most of the subsequent controversy on the nature and role of capitalism has stemmed. For Marx, capitalism was a 'mode of production' in which there are basically two classes of producers: the capitalists, who own the means of production (capital or land), make the strategic day-to-day economic decisions on technology, output and marketing, and appropriate the profits of production and distribution; and the labourers, who own no property but are free to dispose of their labour for wages on terms which depend on the numbers seeking work and the demand for their services. This was essentially the definition adopted, for example, by non-Marxist economic historians such as Lipson and Cunningham and by Marxists such as Dobb (1946).

Given this perspective, it is primarily the emergence of a dominant class of entrepreneurs supplying the capital necessary to activate a substantial body of workers which marks the birth of capitalism. In England, and even more emphatically in Holland, it can be dated from the late sixteenth and early seventeenth centuries. Holland's supremacy in international trade, associated with its urgent need to import grain and timber (and hence to export manufactures) enabled Amsterdam to corner the Baltic trade and to displace Venice as the commercial and financial centre of Europe. The capital thus amassed was available to fund the famous chartered companies (Dutch East India Company 1602; West India Company 1621) as well as companies to reclaim land and exploit the area's most important source of industrial energy—peat. It also provided the circulating capital for merchants engaged in the putting-out system whereby they supplied raw materials to domestic handicrafts workers and marketed the product. Specialization within agriculture drew the rural areas still further into the money economy, and the urban areas supplied a wide range of industrial exports to pay for essential raw material imports.

Dutch capitalists flourished the more because they were subject to a Republican administration which was sympathetic to their free market, individualist values. In England, where similar economic developments were in progress in the sixteenth and early seventeenth centuries, the rising class of capitalists was inhibited by a paternalistic monarchical government bent on regulating their activities for its own fiscal purposes and power objectives and in terms of a different set of social values. The Tudor system of state control included checking enclosures, controlling food supplies, regulating wages and manipulating the currency. The early Stuarts went further in selling industrial monopolies and concessions to favoured entrepreneurs and exclusive corporations and infuriated the majority whose interests were thus damaged. The English capitalists carried their fight against monopolies to the Cromwellian Revolution. When the monarchy was restored in the 1660s, the climate of opinion had been moulded by religious, political and scientific revolution into an environment which favoured the advancement of capitalism and laid the foundations for its next significant phase—the Industrial Revolution.

Orthodox economic theorists eschew the concept of capitalism: it is too broad for their purposes in that it takes into account the social relations of production. Modern economic historians adhering to an orthodox framework of economic theory also tend to avoid the

term. They do, however, recognize a significant aspect of capitalism by emphasizing the rational, profit-maximizing, double bookkeeping characteristics of capitalist enterprise; and in the post-Second World War debates on economic development from a backward starting-point, there has been a tendency to regard the emergence of this 'capitalist spirit' as an essential prerequisite to the process of sustained economic growth in non-socialist countries (see, e.g. Landes 1969; Morishima 1982; North and Thomas 1973).

The modern debate on capitalism in contemporary advanced economies has revolved around its being an alternative to socialism. Marxist economists follow Marx in seeing capitalism as a mode of production whose internal contradictions determine that it will eventually be replaced by socialism. In the aftermath of the Second World War, when the governments of most developed countries took full employment and faster economic growth as explicit objectives of national economic policy, there was a marked propensity for the governments of capitalist economies to intervene actively and extensively in the process of production. At that stage the interesting issues for most Western economists seemed to be the changing balance of private and public economic power (see Shonfield 1965), and the extent to which it was either desirable or inevitable for the increasingly 'mixed' capitalist economies to converge towards socialism. In the late 1960s and 1970s, when the unprecedented post-war boom in world economic activity came to an end, Marxist economists were able to point confidently to the 'crisis of capitalism' for which they found evidence in rising unemployment and inflation in capitalist countries; but non-Marxist economists had lost their earlier consensus. The economic debate on capitalism is now taking place in a political context which is relatively hostile to state intervention; and those economists who believe that the 'spirit of capitalism', or free private enterprise, is the key to sustained technological progress and that it is weakened by socialist economic policies, seem to carry more conviction than they did in the 1950s and 1960s.

cargo cults

Cargo cults is the name given to millenarian movements of Melanesia, which centre on a belief that specified ritual manipulations and observances will soon bring to the people concerned material rewards, notably manufactured goods, and a better, even paradisiacal, life. The name originates from the frequent use by participants of the Pidgin word *kago* (derived from the English 'cargo') to describe the returns they intend their activities to bring, although having a wider, and in the cult context uniquely Melanesian, connotation.

These small-scale and intense cults usually have messianic leaders who rise up to direct their activities, using relevant traditional belief, reinterpreting myths and manipulating associated symbols to promulgate their syncretized and appealing message. The activities inspired and directed by these 'prophets' frequently disrupt everyday life, as they divert people from subsistence tasks (at times even forbid them), and encourage the pursuit of preparations for the coming millennium. One example is clearing airstrips, and surrounding them with bamboo landing lights, to receive the prophesied aircraft coming with cargo, sometimes to be piloted by the ancestors.

One cult reported in the late 1970s, from the Vanuatuan island of Tanna, centres on the Duke of Edinburgh and his autographed photograph. The people believe that the duke was spirited from their midst at birth, and they have prepared for his return, which they believe is imminent, to cure sickness, rejuvenate the elderly and bring material wealth to all. They have a site ready on a nearby beach where the duke's boat will berth on arrival.

Early reports interpreted such cults as the actions of irrational and deluded people, even in states of temporary collective madness. Sensitive research in post-war years has refuted this dismissive conclusion, showing that cargo cults are a rational indigenous response to traumatic culture contact with western society. Although precipitated by familiarity with, and a desire to possess, the goods of the industrialized world, they have a traditional focus and logic. They turn to traditional beliefs and idioms to cope with a bewildering invasion, and although inappropriate, even comical to us in their misunderstanding of our society and their bizarre interpretation of unintelligible aspects of it (like the role of the Royal Family or aircraft technology), they are neither illogical nor stupid.

The newcomers have material wealth and technical capabilities beyond local people's understanding and imagination and—for tribal societies—irresistible political and

military power emanating from incom-prehensible nation-states. Europeans apparently do no physical work to produce these goods, unlike the politically subjugated local population, many of whom they put to hard labour for paltry returns. Neither do Europeans share their fabulous wealth with others, a direct assault on a cardinal Melanesian value, where giving and receiving is an integral aspect of social life.

Clearly Europeans know something, and the problem for the Melanesians is how to gain access to this knowledge. Unable to comprehend western society and the long-term nature of education, which they interpret as a scheme to dupe them, or the worldwide capitalist economic system and the life of a factory worker, they turn to millenarian cults. A recurring feature in these cults is a belief that Europeans in some past age tricked Melanesians and are withholding from them their rightful share of material goods. In cargo cults the Melanesians are trying to reverse this situation, to discover the ritual formula that will facilitate access to their misappropriated manufactured possessions. They conclude that material goods come from the spirit world and that the wealthy whites are stealing their share; so it is a case of manipulating rituals in order to gain access to them.

An oft-repeated aim is to secure the cargo of the ancestors, who some cultists believe will return at the millennium. They will come to right current injustices. Some cults take on a disturbing racist tone here, probably reflecting the attitudes of the white newcomers, which signal people's discontent with European domination and feelings of impotence. With the coming of the millennium, blacks will become whites, and the whites turn black, and white domination will end.

The relatively frequent pan-Melanesian occurrence of cargo cults in a wide range of disparate cultures, and their recurrence time and again, with modified dogma and ritual, in the same region, testify to their importance to the people concerned. In their expression of tensions, they lend themselves to a range of sociological and psychological interpretations. Although frenetic, short-lived and—to outsiders—disruptive, these cults allow Melanesians who find themselves in a confusing and inexplicable world invaded by technically superior outsiders to cope with the changed situation, even manipulate it, for in some cases their behaviour brings results: desperate governments supply processed food and other provisions to alleviate the resulting, sometimes chronic, food shortages following the disruption of subsistence activities.

cartels and trade associations

Cartels are a common form of collusion in oligopolistic markets. In a market with many sellers (perfect competition) each seller can take the market price as parametric, but in an oligopolistic market firms will be aware that their pricing decisions will affect the decisions of others. It is commonly agreed that isolated profit maximization in an oligopolistic market will lead all producers to have lower profits than would be possible if they colluded. Cartels and trade assoc-iations are descriptions for collusion, the former in markets with a small number of firms, the latter in markets where there are many (100). Cartels vary from gentlemen's agreements to legally binding contracts. In most countries they are illegal, but have often also been formed at government behest, as in Germany and the USA in the 1930s. The objective of a cartel is to raise price and cut quantity to increase industry profits. Although they are commonly observed (and more commonly exist), they are often unstable, as each firm has an incentive to cheat by offering small discounts to gain increased sales. Because every firm can cheat, many will, and cheating will occur unless the cartel is properly policed. Cartels can take many forms, from overt (or covert) agreements to tacit agreements on price leadership in the market. Agreement appears to be easier to reach when numbers involved are modest, products are homogeneous and government regulation lax. Developments in the theory of games, using infinite dynamic game theory with time discounting and plausible retaliation for cheating, have aided our understanding of the topic (see Friedman 1982), but have served only to emphasize the indeterminateness of possible solutions in cartelized markets.

cartography

Cartography is the art and technology of making and using maps to represent locations and spatial relationships. It is an art because these representations typically, but not always, are graphic, and thus instruments of visual communication and visual aesthetics. It is also a technology because map makers use, develop and adapt a wide variety of electronic, mechanical and photographic techniques for storing, retrieving, selecting, generalizing and displaying geographic information. These techniques can affect the appearance of graphic maps as well as the efficacy of map-making and map use. Dramatic changes in the cartographic image reflect profound changes in map-making technology over the past five centuries, particularly since 1970. Maps have become dynamic and interactive, and electronic technology has encouraged an ever more diverse range of specialized cartographic applications.

Most geographers and other scholars regard cartography largely as map authorship, that is, the design and Grafting of geographic illustrations to accompany a verbal narrative. Often there is a division of labour in expository cartography between the author-cartographer, who compiles the maps and writes the text, and a cartographic illustrator or drafter, who produces the artwork. But as word-processing and electronic-publishing technology are displacing the typesetter by making fuller use of the author's key strokes, electronic cartography is displacing the drafter who retraces the map author's delineations. Because the cartographic technician serves as a design filter, to advise authors ignorant or uncertain about map projections, symbols and generalization, electronic cartography calls for a greater awareness of graphic and cartographic principles and practices by both authors and their editors. Electronic cartography also fosters a closer integration of maps and words in multimedia and hypertext presentations as well as in traditional publishing formats of articles, books and atlases. Computers, too, are weakening distinctions between cartographic presentation and cartographic analysis, in which maps are a tool for discovering and understanding geographic patterns and for testing and refining hypotheses.

Map making is also an institutional enterprise, in which government cartographic units compile and publish a wide variety of topographic maps, navigational charts, geographic inventories, and other cartographic products essential for economic development, national defence, environmental protection, and growth management. In addition, commercial firms not only serve governments as contractors but also produce a still wider range of derivative, value-added maps and cartographic databases tailored to the needs of travellers, industries, businesses, local governments, and educators. Because expository cartography depends heavily on institutional cartography for source materials, map authors must be aware of the availability, utility and reliability of government and commercial maps.

Cartography is also a subdiscipline of geography in which scholars either seek more effective means of cartographic communication or treat the map, its derivation and its

impact as an object of study. Most academic cartographers are concerned with training geographers and others in the design and use of maps as well as with developing improved methods of cartographic display. Studies of map design rely on a variety of approaches, including semiotic theory, psychophysics, colour theory, statistics, policy analysis, and subject-testing. Because maps can be largely or subtly rhetorical, other cartographic scholars focus on mapping as a social or intellectual process and on the map's role as an instrument of power and persuasion. Despite the hyperbole of cartographic chauvinists who assert that the field is fundamentally a science, maps are subjective texts that reflect the biases of their authors and sources as well as the limitations of technology.

case study

The case study is widely and variously used across the whole range of social science disciplines. It refers to both an organizing principle for and a method of social research. Simply put, case study describes any form of single unit analysis. An individual may be the focus for a case study, as in psychotherapy or medicine, but so may an organization, a group, an event or a social process. The point is that the focus is upon a naturally occurring social phenomenon rather than an experimentally constructed activity or selected sample. Thus, Smith (1990:11); writing about educational research, says:

> The relative emphasis on what I call an 'intact', 'natural' or 'ongoing' group versus some kind of sampled set of pupils, teachers, classes, curricula or schools also seems very important. I believe that this is what some of the case study advocates mean by 'case'.

Cases are not normally selected by criteria of typicality but on the basis of theoretical significance or particular critical qualities.

Case study is based upon depth; more specifically it is holistic and exhaustive. The aim is for what Geertz (1973) calls 'thick description', which is so essential to an understanding of context and situation. An eclectic variety of types of data are collected and set against one another in the processes of analysis and in the representation of 'the case' in writing. Where appropriate and feasible, researchers themselves are central to the conduct of case study research. Data are collected by direct presence in the site, or face-to-face exchange with the subject. The researcher aims to share experiences with the researched, to witness events firsthand, to question action within the setting. The design and conduct of case study research is responsive and creative, accommodating to the form, rhythm and possibilities of the setting. 'Any case study is a construction itself, a product of the interaction between respondents, site and researcher' (Lincoln and Cuba 1990:54). This is typically reflected in the language of case study reporting; 'case studies will rhetorically exemplify the interpersonal involvement which characterized that form of inquiry' (Lincoln and Cuba 1990:59). This contrasts with the 'stripped down, cool' style of 'scientific' reporting. Case studies are written to convey authenticity, to recapture the natural language of the setting and to evoke a vicarious response from the reader.

Case study research is frequently attacked for its lack of generalizability (Bolgar 1965; Shaunhessy and Zechmeister 1985) although in some respects the importation of generalization arguments from the field of quantitative research is based upon misunderstandings of the purposes of case study research. The case study is not premised on the generation of abstract, causal or law-like statements. Rather, it is intended to reveal the intricate complexities of specific sites or processes and their origins, interrelations and dynamics. However, the evolution of the approach and the defence against the generalization argument, the escape from what is called 'radical particularism', has led, in some fields, to the use of multi-site case study research designs. These concentrate upon a limited range of issues across a number of settings, collecting the same data and using the same analytical procedures. Firestone and Herriot (1984) examined twenty-five such studies, which ranged in scope from three sites to sixty. Both the number and the heterogeneity of sites have been used as a basis for claims about more robust generalizability. However, the basic issue of the value of breadth rather than depth applies as much when considering single as against multi-site case studies as it does when the single case study is set over and against survey research. The key question is, what is lost and gained in the trade-off between exhaustive depth and more superficial breadth?

caste

Caste systems have been defined in the most general terms as systems of hierarchically ordered endogamous units in which membership is hereditary and permanent (e.g. Berreman 1960). On such a definition a whole range of rigidly stratified societies would be characterized by caste—Japan, for example, or certain Polynesian and East African societies, or the racially divided world of the American Deep South. Hindu India is generally taken as the paradigmatic example. Many scholars would argue, however, that the difference between this case and the others are far more significant than the similarities, and that the term caste should properly be applied only to this context.

The morphology of the Hindu caste system can be described in terms of three key characteristics (Bouglé 1971 [1908]), all of which are religiously underpinned by the religious values of purity (Dumont 1970). First, there is a *hierarchy* of castes which is theoretically based on their relative degree of purity. As the purest of all the Brahmans rank highest, and are in principle both distinct from and superior to the caste which actually wields politico-economic power. Second, as the pure can maintain their purity only if there are impure castes to remove the pollution that they inevitably incur by their involvement in the natural world, there is a *division of labour* between castes resulting in their *interdependence.* Third, pollution is contagious, and a caste must therefore restrict its contacts with inferiors in order to maintain its status. This *separation* takes many forms: a rule of endogamy precluding marital alliances with inferiors; restrictions on commensality; the outcasting of those who transgress the rules lest they pollute the rest of the group, and the phenomenon of Untouchability debarring physical contact between 'clean' and 'polluted' groups. (We even have historical reports of theoretically Unseeable castes; while in parts of traditional Kerala the relative status of non-Brahman castes was in theory precisely reflected in the number of paces distant they had to keep from the highest Brahmans.)

While the (upward) mobility of *individuals* is theoretically impossible and empirically rare, the group as a whole may lay claim to a higher status by emulating the customs and practices of its superiors, and may succeed in validating its claims by using a new-found political or economic leverage to persuade erstwhile superiors to interact with it on a new basis (the crucial test being their acceptance of its food and water). As the actors present

it, however, this is not a matter of social climbing but of reasserting a traditional status quo which was temporarily disrupted. A theory of timeless stasis is thus preserved despite a good deal of actual mobility.

The system is often visualized as being like a layercake with each layer as an occupationally specialized group characterized by endogamy and unrestricted commensality. A better image is of a set of Chinese boxes. At the most schematic level, contemporary Hindus, following the scriptures, represent the caste order in terms of a fourfold division: Brahman, Kshatriya, Vaishya and Shudra. At the local level (the details vary considerably), the Brahmans may be subdivided into priestly and non-priestly subgroups, the priestly Brahmans into Household-priests, Temple-priests and Funeral-priests; the Household-priests into two or more endogamous circles; and each circle into its component clans and lineages, who may be the only people who will freely accept one another's food. The answer to the question 'What is your caste?' will depend on context and might legitimately be phrased in terms of any of these levels. At each level the group is referred to as a *jati*, a term which is conventionally translated as 'caste' but is more accurately rendered as 'breed' or 'species'. Groups which share a common status in relation to outsiders are internally hierarchized: all Brahmans are equal in relation to non-Brahmans, but non-priestly Brahmans are superior in relation to priestly ones, and Household-priests in relation to Funeral-priests. It will be seen that the occupationally specialized group is not necessarily coterminous with the endogamous group, which may not coincide with the unit of unrestricted commensality. It is therefore impossible to define caste by listing a series of characteristics (e.g. occupation, endogamy, etc.) common to all. The universe of caste is a relational universe, rather than one made up of a given number of fixed and bounded units.

census of population

A census of population, as defined in United Nations reports, is the total process of collecting, compiling, evaluating, analysing and publishing, or otherwise disseminating, demographic, economic and social data pertaining to all persons in a country, or to a well

delimited part of a country at a specified time.

The census of population is the oldest and most widely distributed statistical undertaking by governments throughout the world. Censuses have also been developed to provide information on housing, manufactures, agriculture, mineral industries and business establishments. Many of the principles applying to the census of population apply equally to these other censuses.

It is not known which ruler first ordered a count of the people in order to assess the numbers potentially available for military service or to determine how many households might be liable to pay taxes. Population counts were reported from ancient Japan, and counts were compiled by Egyptians, Greeks, Hebrews, Persians and Peruvians. Many of these early censuses were limited as to the area covered and in some instances dealt with only a part of the population, such as men of military age. The results were generally treated as state secrets. In Europe, censuses on a city-wide basis were reported in the fifteenth and sixteenth centuries. India reported a census in 1687. Various censuses have been claimed as the first in modern times.

Data collected in a population census have often been used as the basis for the allocation of a territory to one or the other claimant governments. Census data are widely used by governments for planning and carrying out a variety of governmental functions. In some countries representation in legislative bodies and distribution of funds by the central government are significantly affected by the census results. The powers and duties of many municipalities depend on the size of their population. The private economy makes extensive use of the data for site locations, marketing strategies, and many other activities. Health, education and welfare programmes depend very heavily on such data.

The oldest continuous census taking is that of the USA where a census has been taken every ten years since 1790. The United Kingdom began taking a census in 1801 and followed the ten-year pattern except in 1941 when wartime requirements led to its cancellation. The ten-year pattern is widely observed. In many countries the census is authorized anew whenever the government finds a need for the data. In a few countries censuses are taken at regular five-year intervals. During the 1970s special efforts by the United Nations and some donor countries were directed to assisting African countries which had not previously taken a census. In 1982 the People's Republic of China completed the largest census ever taken. By 1983 virtually every country in the world had taken at least one census of population.

Early censuses often utilized household lists or similar sources as the basis of their tabulations. A modern census is one in which information is collected separately about each individual. Such practices became common during the last half of the nineteenth century.

The information assembled in a census depends in large part on the needs of the government for such information and on the availability of alternative sources. The United Nations has identified a set of topics which appear most essential. They include place where found at time of census, place of usual residence, place of birth, sex, age, relationship to head of household, marital status, children born alive, children living, literacy, school attendance, status (employer, employee, etc.). International comparability will be facilitated to the extent that national census offices utilize the standard definitions which have been developed by the United Nations.

A question which needs careful attention prior to a census is who is to be counted as part of the national and local population. Special consideration needs to be given to such persons as members of the Armed Forces, including those stationed outside the home country, migratory workers, university students, technical assistance personnel outside their home countries, long-term visitors, and guest workers.

Having determined who is to be included in the census, it becomes necessary also to determine in which part of the national territory they are to be counted. The classic distinction is that between a *de facto* and a *de jure* census. In a *de facto* census people are generally counted as a part of the population of the place where they encountered the census enumerator. This differs from the practice in a *de jure* census where an effort is made to ascertain where the person 'belongs'. This may be a usual residence, a legal residence, or an ancestral home. Persons who spend part of the time in one place and the remainder in one or more other places, and persons in long-stay institutions (prisons, hospitals, etc.) need to be recorded in a uniform manner within the country. Special procedures may need to be developed for persons who have no fixed place of residence, such as persons who live on the streets, nomads, refugees, or illegal aliens.

Customarily two basic methods of taking the census are recognized—direct enumeration and self-enumeration. Under the former method the enumerator collects information directly from the household. Self-enumeration means that the household members are given a questionnaire with the request that they enter the appropriate information and deliver the completed form to the designated census office or to an enumerator who comes to collect the completed forms.

The law establishing the census normally makes provision for the authority of the census office and its employees to conduct the census and establishes the obligation of the residents to provide the answers to the best of their ability. There are normally legal penalties for refusal or for providing false information.

An important part of the legal provision for the census is the guarantee that the individually identifiable information will be held in strict confidence and will be used only for statistical purposes, and violation of pledge of confidentiality is a punishable offence.

The almost universal availability of computers for the processing, tabulation and printing of the data collected in the census has greatly facilitated the work of census offices. A more complete and thorough review of the raw data as well as of intermediate and final tabulations is possible, and where the research community also has access to computers the provision of summary tapes and of public use microdata sample tapes has enabled them to use the data more effectively.

The improved access of the public to the census products has greatly increased the concern over errors in the census from whatever source, whether in coverage of the population, errors by the respondents, errors in recording the information supplied by respondents, or errors made in the processing of the data, and census officials are alerted to this problem.

Computers and the development of sampling procedures have brought about significant changes in the conduct of population censuses. The effective use of computers has brought about changes in field procedures and has speeded up the tabulation and release of the results. They have led to the preparation of data for specialized purposes.

They have contributed to procedures for making microdata available for research purposes, while protecting the confidentiality of the individual records.

The quality of census results has come under increasing study. The completeness of the coverage is critical for many governmental actions. Special efforts have been undertaken to ascertain the completeness of the census results. Methods of ascertaining the degree of under- or ov.rcounting of the population of a given area have yielded valuable information. Special attention has been given to sources of data within the census operation which can yield the information required. The treatment of members of minority groups—ethnic, age, occupation, country of birth, etc.—can have profound effects on the data and public actions for or against members of the groups.

Related sources of information, such as a population register, can be used very effectively in all phases of the census. Training and supervision of the staff are critical to the success of a census. Special arrangements may be needed if the census work in essence is a parttime activity by persons who have other duties. A different set of procedures is needed if the bulk of the census is carried on by persons who are recruited for the census.

Conrad Taeuber

centre and periphery

The two concepts centre and periphery form part of an attempt to explain the processes through which capitalism is able to affect the economic and political structure of underdeveloped or developing societies. Drawing on the Marxist tradition, this view assumes that in the central capitalist countries there is a high organic composition of capital, and wage levels approximate the cost of reproducing labour. By contrast, in the peripheral countries, there is a low organic composition of capital, and wages are likely to be low, hardly meeting the cost of reproducing labour. This happens because in

peripheral areas reproduction of labour is often dependent on some degree of non-capitalist production, and the wages paid to workers are subsidized by subsistence production. In some cases, such as with plantation workers, smallholder plots may contribute as much as the actual money wage paid, or in mining, the migrant male wage labourer may receive a wage which supports him but not his family, who depend on subsistence production elsewhere. In the centre, wages are determined largely by market processes, whereas at the periphery non-market forces, such as political repression or traditional relations of super- and subordination (as between patrons and clients), are important in determining the wage rate.

The use of the concepts centre and periphery implies the world-system as the unit of analysis, and 'underdevelopment' as an instituted process rather than a mere descriptive term. Underdevelopment is the result of contradictions within capitalist production relations at the centre. It is the outcome of attempts to solve these problems and is a necessary part of the reproduction of capitalism on a world scale.

Attempts to analyse the processes of surplus extraction, together with the claim that the world economy had become capitalist, gave rise to two major interrelated debates. One concerned the precise definition of capitalism and whether it is to be satisfactorily characterized by a specific system of production or of exchange relations. The other tried to identify the links between centre and periphery, and thus the nature of the system, in terms of the relations or articulations between different modes of production. In trying to clarify these theoretical issues together with their political implications, the use of the terms centre and periphery was elaborated and empirically researched. This gave rise to various forms of world-system theory, represented in the writing of Wallerstein (1974), Frank (1978) and Amin (1976); it also revived interest in theories of national and global economic cycles, for example in the work of Mandel (1980). In addition, in attempting to explain the position of countries such as Brazil, Argentina and Mexico, the concept of the semi-periphery was developed. This concept involves the idea that their particular political cultures and the mixed nature of their industrialization places these countries in a buffer position, particularly in their international political stance, between central capitalist countries and those of the true periphery.

charisma

Charisma is one of the more contentious sociological concepts, in part because it has been absorbed into popular, or at least mass media, usage in a considerably adulterated form. The term derives from a theological conception which referred to the divine gift of grace. Max Weber developed its sociological use by extending it to refer to the recognition in individual leaders by their followers of supernatural or super-human powers or qualities of an exemplary kind or of transcendental origin.

Weber's formulation gave rise to ambiguities. On the one hand, it could be argued that the nature of charisma inhered in the powers or qualities displayed by the individual, and thus was to be explained primarily in terms of the personal psychological attributes of the leader. On the other hand, it could be argued that the character of charisma lay in the recognition extended by the following, and thus was to be explained primarily in terms of the social psychological features of the interpersonal relationship between leader and followers. Common usage bears elements of both approaches, identifying the charismatic figure as one who displays personal attractiveness or force-fulness of a kind which leads to great popularity or popular devotion. However, this is quite antithetical to Weber's central thrust.

Weber sharply contrasts charisma with forms of authority deriving from tradition and from rationalistic or legal considerations. The charismatic leader is one who breaks with tradition or prevailing legal norms, and demands obedience on specifically irrational grounds of devotion as God's Prophet, the embodiment of transcendental forces, or as possessor of supernatural powers. Conventionally elected leaders, or heirs of an established tradition, cannot therefore be construed as charismatic because of their attractiveness or popularity or even both.

The following of a charismatic leader offers its obedience and devotion in virtue of the mission upon which it believes the leader to be engaged and the transcendental forces which the leader manifests. But it may require periodically to be reassured of the possession of those powers, demanding signs of the miraculous as the price of commitment.

The charismatic leader operates through a body of disciples or other personally devoted inner circle rather than an established administrative staff. Often—especially in the case of religious charisma—it may consist of members of the leader's immediate household, living in an intimate and emotionally laden communal relationship with the leader. They receive their appointment not on the basis of technical expertise, but rather because of the intensity of their devotion or willingness to subordinate themselves to the leader's will. They are commissioned to carry out that will on an *ad hoc* basis. There is no administrative routine, or any such routine is short-lived, constantly disrupted by the intervention and revelation of the leader. The economic basis of the movement is irregular and founded on booty or free-will offerings. Decision making is erratic and

inspirational.

Charisma is inevitably a precarious form of authority. Max Weber maintained that it could exist in its pure form for only a relatively brief period. In the course of time it tends to become transformed into a less spontaneous or less unpredictable form of leadership, towards traditionalism or rational-legal authority. Such a development appears to be an ineluctable consequence of perpetuating the movement's mission or of spreading it beyond an immediate, local band of disciples. Endurance over time or wider spread is likely to introduce the need for mechanisms of co-ordination, supervision and delegation. In consequence there will arise increasing impersonality and routine and the desire for greater stability and predictability on the part of officials.

The problem of succession often accelerates the process of routinization. The charisma of the founder is vested in another by virtue of hereditary succession or a ritual of consecration. Thus, such forms as 'hereditary charisma' or 'charisma of office' become an intervening step in the transformation of authority in a traditionalistic or rational-legal direction.

Chicago School

The so-called Chicago School of economics, chiefly American, is a neo-classical counter-revolution against institutionalism in economic methodology, against Keynesian macroeconomics, and against 'twentieth-century liberalism', i.e. interventionism and *dirigisme,* in economic policy generally. Its centre has been the University of Chicago, where it first achieved prominence in the 1930s. Its intellectual leaders until about 1950 were Frank H.Knight in matters of theory and methodology and Henry C.Simons in matters of economic policy. During the next generation, the leaders have been Milton Friedman, George Stigler and Gary Becker. Many economists not trained at Chicago have aligned themselves with many 'Chicago' positions, and many members of the Chicago economics faculty, to say nothing of its graduates, have dissociated themselves from 'Chicago' doctrine.

Some characteristic Chicago School views have been as follows:

1 Methodological positivism. The validity of a theory depends neither upon its generality nor upon the plausibility of its initial assumptions, but exclusively upon the confirmation or disconfirmation (primarily statistical) of such of its implications as diverge from the implications of alternative theories.
2 Acceptance of market solutions for economic problems, not in any Utopian or optimal sense but in aid of political and intellectual freedom. Chicago School economists see the market economy as a *necessary* condition for free societies generally. It is not, however, a *sufficient* condition.
3 Distrust of administrative discretion and *ad hoc* intervention in economic policy. Preference for 'rules versus authorities' in matters of monetary and fiscal policy.
4 Monetarism rather than fiscalism in macroeconomic regulation.
5 The use of fiscal measures to alleviate poverty, but distrust of redistributionism above the poverty line.
6 Disciplinary imperialism, by which is meant the applicability of economic analysis by economists to problems normally restricted to other disciplines, such as history, politics, law and sociology.

The school's positions with regard to a number of topics, especially trade regulation and monetary policy, have changed over the years. Simons, for example, believed in the active maintenance of competition by a strong anti-monopoly or 'trust-busting' policy, while Friedman and Stigler thought monopoly and oligopoly to be only short-term problems of minor long-term significance. Simons also believed that monetary policy should be guided by a price-level rule—expansionary when the price level was falling and contractionary when it was rising. Friedman, impressed by the long and variable time-lags involved in price-level reactions to monetary change, has favoured a constant rate of monetary growth.

Following the retirement and death of Stigler, and the retirement of Friedman and his move to the Pacific coast, Chicago's own economists have become at once less directly concerned with public policy and more frequently honoured by Nobel Prizes and other awards for pure economic, financial and historical scholarship. In macroeconomics, Robert Lucas has become a leader in the 'new classical' or 'rational expectations' approach to research in monetary and financial economics. In fact, in the mid-1990s, Lucas and Gary Becker may be considered the guiding spirits if not yet the elder statesmen of the Chicago School, replacing Friedman and Stigler.

The two best summaries of Chicago doctrine are Simons's (1938) *Economic Policy for a Free Society and* Friedman's (1962) *Capitalism and Freedom.*

childcare

Childcare is taken to refer to state policy regarding the care of children, and more generally to ideas and practices concerning the care of children. State agencies may be involved with the provision of substitute or alternative care where family caring mechanisms have broken down, and with the provision or regulation of care for children during the day or for short periods when parents are not available to care. An extension of this role may be to provide support and supervision for families where there is some doubt about the standards of childcare.

A major concern since the 1970s is the abuse of children, both physical and sexual, due partly to the discovery that both forms of abuse were more common than previously thought, and to 'scandal' cases where care agencies were unable to prevent child deaths at the hands of a parent or parent figure (for example the case of Maria Colwell in Britain in 1973). This led to anxiety about the risk to children from their own birth or genetic parents, about returning children from substitute care to a parental home where care might be inadequate, and about situations where children's lives were disrupted by constant moves back and forth from substitute to birth parent care. The focus on abuse and the debate about the appropriate role for the state continued into the 1980s and 1990s.

A number of perspectives have been outlined by Fox Harding (1991) on how the state might proceed in relation to children and their families where there is concern about the quality of care. These views connect with wider ideas about child psychology, the importance of genetic relatives, and the broader role of the state. The first perspective is concerned with independent and secure, permanent families, be these birth families or substitute families, and a minimum role for the state. The second perspective is concerned primarily with poor parental care and the necessity of firm state action to protect children. The third perspective is concerned above all with the original family unit, its importance for the child, and the need to support deprived families by means of various services. Finally, there is a 'children's rights' perspective.

Of interest for the future is the fourth perspective emphasizing the *rights* of children as actors independent of adults or state agencies. At its extreme, this allocates to children rights identical to those of adults such as the franchise and the right to work (see, e.g. Farson 1978; Holt 1975). While most would find the granting of all adult rights and freedoms to children impracticable, and not necessarily in the interests of children themselves, a more moderate form of the 'rights' emphasis has found expression in the greater ability of children under the law to express a view, give evidence, and apply to

live in a particular home (e.g. under the Children Act 1989 in Britain); in campaigns against corporal punishment of children (e.g. Newell 1989); and in the UN Convention on the Rights of the Child 1989, the first international legal instrument on children's rights, which explicitly states that children have a right to a say in processes affecting their lives (Freeman 1993).

The 1980s and 1990s saw matters of childcare policy debated against a background of policies of reducing public expenditure and contracting of the role of the state. In the childcare context this has meant an increased emphasis on parental rather than state responsibility. There has also been a concern about the increased number of mother-headed families, and the loss of the father's role from the family, both in terms of financial support, and his disciplinary and general caring role. Attempts have been made to extract more by way of maintenance payments from 'absent' fathers, for example under the Child Support Act 1991 in Britain, which was itself modelled on schemes operating in Wisconsin and in Australia. The concern about the 'disappearance' of the father's role has also been linked with wider problems of social breakdown and disorder (e.g. Dennis and Erdos 1992).

Childcare remains a controversial area, and differences of view arise between those who hold different ideas about the role of the state, the role of the family, the roots of abuse and poor childcare, and the nature of childhood itself.

childhood

For most periods of history and for most children in the world, childhood is *not* ideally cosy, protected, playful and free from adult responsibilities; in practice, a child's survival in hostile conditions is often the first challenge that the child faces (see Scheper-Hughes 1987). The UN Convention on the Rights of the Child 1976 accordingly sought to establish not 'the best' but progressive realization of the 'best possible' standards respecting the economic, social and cultural rights of children.

The idea of childhood is historically and culturally variable. Philippe Aries (1962 [1960]) argues that in Europe childhood began to be marked as a distinctive stage of life only in the thirteenth century. The conception of childhood altered radically in the seventeenth century with the rise of modern notions of the family and of the school, and again in the nineteenth century. The modern world is 'obsessed by the physical, moral and sexual problems of childhood' (Aries 1962 [1960]: 411).

If Aries is right, it cannot be sheer coincidence that the most influential theorists in the history of psychology—Sigmund Freud and Jean Piaget—were concerned to understand childhood and how children come to be adults. Freud focused on sexual identification and the development of conscience. The child becomes a moral being via the control by guilt of sexual and aggressive impulses. Piaget (e.g. 1926; 1935) devoted his life to describing how the child cognitively constructs the concepts that allow for an effective adult engagement in the world, such as those of number, time, physical causality, measurement, etc.

Behaviourist psychologists tried to show how, like other animals, children are 'conditioned' to behave in certain ways through encounters with their environment, including other people, that yielded rewards and punishments. The increasing sophistication of biology-based studies of animal behaviour and cognitivist studies of humans revealed difficulties with learning theory, but the notion that children are 'conditioned' by their environment proved particularly congenial to sociologists and anthropologists who were less concerned with the child as 'individual' than they were with the child as a member of a collectivity. For example, the anthropologist Margaret Mead, whose best known works focus on childhood and adolescence, ascribed to cultural conditioning the fact that *what* children learn is culturally appropriate and *how* they learn is culturally mediated too. Data on child-rearing practices were also of special significance for those 'culture and personality' theorists who were interested in the cross-cultural applicability of psychoanalytic theory (see, e.g. Whiting and Child 1953).

However, with the export of Piaget's ideas to the USA and the increasing dominance of cognitivist explanations in psychology during the 1960s and 1970s, the idea of the child as conditioned by the environment or, more radically, as imitating adult behaviour, gave way to 'socialization' theories, according to which the child was actively engaged in

knowledge processes.

Piaget was criticized by his Russian contemporary Vygotsky for failing to incorporate historical (i.e. sociocultural) parameters and social interaction in his account of childhood cognition (see, e.g. Vygotsky 1962 [1934]), and by others because he did not recognize how extensive are a child's earliest cognitive abilities (see, e.g. Smith *et al.* 1988), nor how early infants form a sense of an emergent self which actively shapes their interactions with others (e.g. Stern 1985).

While psychological models of childhood long stressed the active and *transformative* nature of cognitive developmental processes, they also tended to suggest that the end-products of cognition are known. Particularly in anthropology and sociology the child was regarded as a more or less passive receiver of collectively constituted, and adult, ideas. However, since the 1980s there have emerged a number of interdisciplinary approaches to the project of understanding childhood. These studies emphasize the idea of the child as *agent,* as a producer as well as a product of the dynamic collective processes we characterize as 'history' (see, e.g. Kessel and Siegel 1983; James and Prout 1992). Children inevitably differentiate themselves from their parents and, in so doing, they establish historically specific forms of social relations that will manifest at once both cultural continuity and cultural change. This approach directs attention to how children cognitively construct over time concepts that refer to domains that we have been used to think of as distinctively adult—kinship or political economy or religion (see, e.g. Toren 1990). Under the stimulus of new theoretical approaches, the study of childhood in anthropology and sociology may come to have the same importance for theory in these disciplines as it has always had in psychology.

Chomsky, Noam (1928–)

Noam Chomsky, language theoretician, philosopher, intellectual historian and social critic, is one of the most profound and influential thinkers of the modern period, and one of the few scientists whose works are widely read.

After receiving a PhD in linguistics from the University of Pennsylvania in 1955, he joined the faculty at the Massachusetts Institute of Technology, where he was promoted to full professor in 1961, appointed to an endowed chair in 1966, and made institute professor (one of a handful, most of them Nobel laureates) in 1976. Many of the most distinguished contemporary linguists were once his students, some of whom continue to find his work inspiring. (He has supervised about one hundred doctoral dissertations to date.)

His most original contribution has been to open the way to the cognitive natural sciences, for which he has provided a model that is still without equal. (He received the Kyoto Prize for 'basic sciences' in 1988.) His specific model for human language, often referred to as (transformational) generative grammar, can be regarded as a kind of confluence of traditional, and long-forgotten, concerns of the study of language and mind (as in the work of Wilhelm von Humboldt or Otto Jespersen) and new understanding provided by the formal sciences in the late 1930s, specifically, recursive function theory, also known as the theory of computation. His rather unusual knowledge of philosophy, logic and mathematics also allowed him to make use of more sophisticated techniques in linguistics than were being used when he appeared on the scene (and to go on to develop, in the late 1950s, algebraic linguistics, a branch of abstract algebra which is now part of computer science).

However, his original theory of language led in due course (by 1980) to the principles-

and-parameters model (greatly improved in his 'minimalist programme' of the early 1990s) and this new model—the first one ever to suggest a substantive solution to the fundamental problem of language acquisition—constitutes a radical break from the rich tradition of thousands of years of linguistic enquiry, which in a way cannot be said of early generative grammar. It is true that the entire (modern) generative grammar period appears to be in many ways a new era. In retrospect it is clear that it has brought with it quite significant changes and progress in the study of language. New areas of enquiry have been opened to serious investigation, leading to many insights and deeper understanding. Furthermore, the current rate of change and progress is rapid even by the standards of the 1960s, so that the generative grammar of the first decade of the twenty-first century may be as novel to us as present-day generative grammar would be to linguists of the not too distant past. If the thinking along the lines of the minimalist programme is anywhere near accurate, it might not be unreasonable to expect that 'a rich and exciting future lies ahead for the study of language and related disciplines', as Chomsky believes in the mid-1990s.

One of the most important consequences of his technical work is that it provides what appears to be decisive evidence in support of epistemological rationalism, as he was quick to point out. It is no secret that Chomsky was greatly influenced by developments in philosophy from the very beginning, and that he turned to the serious study of the Cartesian tradition, which he was to revive and update, shortly after he made his revolutionary discoveries. It was these discoveries that made it possible for him to go well beyond the programmatic, nonspecific insights of the Cartesians, and give substance, at long last, to central Cartesian claims, in the process reconstructing the enduring ideas of the first phase of the age of modern philosophy (a not always recognized antecedent of the cognitive revolution of the 1950s), on which Chomsky has shed much light as a very insightful intellectual historian.

For Chomsky, as for Descartes, there is no essential variation among humans (no 'degrees of humanness') apart from superficial physical aspects: a creature is either human or it is not. Racism, sexism and other inegalitarian tendencies are then a logical impossibility under this conception, if consistently applied. This conviction, which his technical linguistic work shores up to some extent, is at the root of his broader, more searching studies of human nature and society, and on the grounding of concepts of a social order in features of human nature concerning which empirical enquiry might provide some insight. This is not to say that he, or anyone else, has been able to provide a specific model for the study of social structures, that is, a sort of 'universal grammar' (a new cognitive science) of possible forms of social interaction comparable in depth to the model he has provided for linguistic structures, something possible in principle for other cognitive domains, in his view (which provides an entirely new perspective on the humanities and the social sciences). Still, his social and political theory, which takes an 'instinct for freedom' and the associated urge for self-realization as our basic human need (as distinct from our merely animal needs)—drawing heavily on his superb sympathetic acquaintance with the modern history of social struggle and the ideals underlying it— does not lack inner coherence, is consistent with what is currently known, and compares favourably with any available alternative.

However, the bulk of Chomsky's 'non-professional' writings, which by now are

voluminous, and of his numerous and well-attended talks, is devoted not to social and political theory but to a painstaking analysis of contemporary society, to which he brings the intellectual standards taken for granted in scrupulous and profound disciplines (in addition to a hard-to-match brilliance and just plain decency). Because of the broad range, the massive documentation and the incisiveness of this work he is widely recognized as the foremost critic of the foreign and domestic policies of the world's number one (and now only) superpower.

citizenship

Only a state, that is, an internationally recognized entity, can grant a person citizenship. One cannot be a citizen of an ethnic group or of a nationality which is not organized as a state. Nor is citizenship confined to democratic states. The distinction between citizens (who belong to a republic) and subjects (who belong to a monarchy) became obsolete when democracy matured in states that retained a monarchical façade. Non-democratic states would not now tolerate the international stigmatization of their population by a refusal to term them 'citizens'.

Citizenship is a legal status defined by each state. Rights and obligations are nowadays ascribed equally to all citizens, since it has become inexpedient to acknowledge the

existence of second-class citizens, whether on the basis of place of birth or residence, gender, beliefs, behaviour, race or caste. 'Civil' rights protect their safety and their ability to act. Raymond Aron (1974) affirms that 'modern citizenship is defined by the Rights of Man', but ancient polities (e.g. the Roman Empire) emphasized liberties and procedural guarantees on behalf of their recognized members. In addition to these civil rights, other rights, again supposedly modern, are termed social rights or entitlements. These entitle the citizen to some level of well-being and of social (i.e. socially guaranteed and organized) security. It should not be forgotten, however, that ancient states had their own forms of entitlements, the *panem et circenses* of Rome being inconsiderable when compared to the state socialism of some ancient empires in America or Asia. Moreover, civil rights, true prerequisites of democracy, have for centuries been viewed as 'natural' possessions of individuals, which had only to be protected from the state (hence their often negative description: 'Congress shall make no law…abridging the freedom of speech or of the press'). Social rights, in contrast, are popular aspirations which are not always enforceable, even where they are endorsed by the state, because of socioeconomic or ideological constraints. Westbrook (1993:341) therefore suggests that 'a civil right is thus defined in spite of ordinary politics; a social right is defined by the grace of ordinary polities'.

The duty of the citizens is to obey the laws of the state: 'subjection to the sovereign is the defining characteristic of citizenship' (Camilleri and Falk 1992:18). Serving the state, from paying taxes up to risking one's life in its defence, is part of civic duty. However, most political philosophers have stressed that the state exists to serve the citizens: hence it is necessary for the citizens to assert political control over the state in order to ensure that their civic responsibilities do not become too heavy in proportion to their rights.

It is therefore easy to understand why citizenship, originally merely a classification of membership, has become enmeshed with the three most formidable ideological currents of modern times: nationalism and democracy, which advocate an active, dedicated citizenship, and tend to reject on the one hand the non-patriots and on the other hand the non-democrats; and third, but not least, the ideology of the welfare state, which emphasizes a passive, consumer-like citizenship and which merges easily with the Hobbesian view of a profitable authority. These three conflicting ideologies are themselves internally divided on such issues as the relevance of ethnicity for the nation, and of majority rule for democracy. In consequence of these ideological conflicts being grafted upon it, the juridical notion of citizenship is sure to remain a matter of urgent public debate for many years to come.

city

Terms like the city, urban and urbanism relate to a wide range of phenomena, which have varied greatly through history and between world regions. Different disciplines develop their own perspectives towards urban phenomena: there is an urban anthropology, an urban economics, an urban geography, an urban sociology, etc. Conceptions of the urban community are not congruent between different languages: the English town/city distinction does not have direct counterparts even in closely related languages.

We may regard a reasonably large and permanent concentration of people within a limited territory as the common characteristic of all cities and other urban places. Scholarship has focused on the role of such communities within the wider society, and on the particular characteristics of their internal life.

The beginnings of urbanism are now usually identified with a broad-type of ritual-political centre which developed apparently independently in six areas: Mesopotamia, the Nile and Indus Valleys. North China, Mesoamerica, the Andes, and Yorubaland in West Africa (Wheatley 1971). In these centres divine monarchs and priesthoods, with a corps of officials and guards, controlled the peasants of the surrounding region and extracted a surplus from them. What may have begun as modest tribal shrines were elaborated as complexes of monumental architecture: temples, pyramids, palaces, terraces and courts. We find here the early history not only of the city, but also of civilization and the state. The Yoruba towns, last of the kind to emerge independently, but the only ones still existing as ongoing concerns in a form at all resembling the original, have not exhibited the complexity of architecture and other technology of the earlier and more famous cases but show similarities of social form.

The early centres were urban especially through their capacity to organize the countryside around them, evidently mostly through symbolic control. Yet they might have small residential populations, and most of the people under their rule came to them only for major ritual events. In this sense, one may see the centres as marginally urban. Over time, however, warfare and other factors tended to lead to more secular forms of political control, as well as to greater population concentrations at the centres themselves. The same development can be discerned in European antiquity. In *La Cité antique* (1864)

(The Ancient City), Fustel de Coulanges has described its urban beginnings as once more a complex of ritual politics, but at the height of their power, the cities of the Graeco-Roman world had elites of landowners and warriors, in control of enormous slave workforces.

These were cities of power, and cities of consumers. Commerce and industry played a minor part within them. But the ancient empires and their cities would decline, and in the Middle Ages, a new urbanism came into being in western Europe. It was mostly commercially based, and with business as the dominant element, the cities developed a considerable autonomy and independence from the feudal social structures surrounding them. The Belgian historian Henri Pirenne is one of the scholars who have been concerned with these medieval European cities. Another is Max Weber, who developed an ideal type in *The City* (1958 [1921]): an urban community must have a market as its central institution, but also a fortification, an at least partially autonomous administrative and legal system, and a form of association reflecting the particular features of urban life (the guild was a conspicuous example).

This frequently quoted formulation constituted a very restrictive definition of urbanism. The distinctiveness of the town in relation to the surrounding countryside is clear, but the institutional apparatus belonged in a particular phase of European history. Weber also contrasted this occidental city with its oriental counterparts. The latter were more internally fragmented and at the same time more closely integrated into imperial administrations. As cities of power rather than of commerce, often with some emphasis on the symbolic expression of pre-eminence, the great urban centres of the east as seen by early European travellers may appear more related to the first urban forms.

Industrialism, of course, has given shape to yet other kinds of cities. One important account of the misery of the huge new concentrations of labouring people in rapidly growing cities is Friedrich Engels's in *The Condition of the Working Class in England* (1969 [1845]), based on his experience in Manchester. Another classic set of studies of urban life under industrialism were carried out by the Chicago school of sociologists—Robert E.Park, Louis Wirth and others—in the 1920s and 1930s. The Chicago sociologists drew attention to the spatial organization of the industrial city and its apparently orderly changes, and thus launched an 'urban ecology'. At the same time, they located a series of smaller-scale ethnographies of particular 'natural areas' within the wider spatial order. Thus they simultaneously pioneered the study of many topics now central to urban anthropology ethnic quarters, youth gangs, occupations, deviant groups and public places.

In a well-known formulation, Louis Wirth (1938) described urban social contacts as 'impersonal, superficial, transitory, and segmental', and the Chicago sociologists were generally pessimistic about the possibilities of achieving a satisfying human life under urban conditions, as a great many other thinkers have also been. (Yet one celebrates the contribution of urbanism to intellectual life.) On the whole, they concerned themselves more with the internal characteristics of the city, rather than with its place in society. This probably contributed to their tendency to generalize about urbanism on the basis of their Chicago experience, instead of emphasizing that this city was a product of a particular American context, including expansive industrial capitalism as well as ethnic diversity in a somewhat unsettled state.

Partly in response to such generalizations, a considerable body of ethnographically inclined research has emphasized the great variety of forms of life which can be found under urban conditions, and not least the fact that informal social organization may indeed be quite different from the type summarized by Wirth's phrase. William F.Whyte's *Street Corner Society* (1943), describing a close-knit Italian-American neighbourhood in Boston, was a noteworthy early study in this vein, and it is by now generally understood that while city life may have its share of impersonality and anonymity, it also contains a web of friendship, kinship, and occupational linkages: in part, it may be a mosaic of 'urban villages'. With the growth of new subcultures and lifestyles, and a new appreciation for cultural diversity in the city, urban ethnography has been further revitalized in North America and Europe.

Similar perspectives have also been important in the study of contemporary urbanism in the Third World. Especially as the process of urbanization accelerated greatly in Africa, Asia and Latin America in the mid-twentieth century, there was first a tendency by commentators to emphasize 'disorganization', 'detribalization', and the weakening of traditional social ties generally. Later studies have tended to point to the security still provided by kinship and ethnicity, the economic and political uses to which they may be put, and the ability of urbanites to evolve new adaptations, even without significant economic means. Research on squatter settlements, especially in Latin American cities, has thus often made the point that such 'informal housing' is often superior in its efficiency to large-scale public housing projects, and a wave of studies of the 'informal sector' of the urban economy has shown that a very large number of people in Third World urban centres make some kind of living through self-employment or less formal employment arrangements, without occupational training in formal educational structures, and with very limited material resources. This sector includes artisans, petty traders, rickshaw drivers, ice cream vendors, shoe shiners, truck pushers and a multitude of other more or less legitimate ways of supporting oneself, as well as a variety of illicit occupations.

One must not exaggerate the capacity of informal modes of organization to solve the problems of urban living, however, in Third World countries or elsewhere, and the debate on such issues is not yet concluded. What is clear is that generalizations about cities and city life must almost always be qualified. There are in fact a great many types of urban centres, each city has many kinds of inhabitants, and every urbanite engages in social contacts and activities of multiple sorts.

This diversity obviously depends to a great extent on the varying relationships between cities and society. Several different research perspectives thus concern themselves with setting urban centres in a wider context. In economic geography and regional science, different models have been developed to deal with the spatial distribution of urban functions within larger areas. Central place theory, first developed by Walter Christaller (1933) in the 1930s, has been a prominent example, dealing with the location of commercial, administrative and transport centres. Geographers have also concerned themselves with the problem of classifying cities according to their major societal functions, and analysing their internal structure as determined by these functions. Among early well-known classifications, for example, is one showing eight types of urban communities in the United States: retail, wholesale, manufacturing, mining, transport,

resort and retirement, university, and diversified. Since the 1960s, one strong interdisciplinary trend has been to view urban processes especially in western Europe and North America within the framework of the political economy of industrial capitalism. This trend, partially under Marxist inspiration, has related urbanism more closely to issues of class, power and social movements (Castells 1977).

In the years since Max Weber drew his contrast between occidental and oriental cities, there have also been numerous further attempts at delineating various regional urban types, such as the Middle Eastern City or the Latin-American City. Cultural historians and other area specialists have played an important part in evolving such constructs, and they have not always been guided by a desire to arrive at a comprehensive comparative understanding of world urbanism. Because of colonialism and other kinds of western expansion, of course, the urban forms of different regions have not all been equally autonomous in their development. Often they must be seen within the context of international centre-periphery relationships. In Africa, Asia and Latin America the large port cities which grew with western domination—Dakar, Bombay, Calcutta, Shanghai, Buenos Aires and others—are an example of this. A recurrent pattern in the colonial and post-colonial Third World has also been the growth of 'primate cities', which through a strong concentration of the commercial, administrative, industrial, cultural and other functions of a country or a territory become much larger and more important than any other urban centre there. Yet colonialism has also created other kinds of urban communities—mining towns, small administrative centres, 'hill stations' for resort purposes, and so forth—and its products may have coexisted with more indigenous urban traditions. Due to such variations, it would seem wiser to look at regional forms of urbanism not always as single types but as typologies in themselves, generated through an interplay of international influences and local forces of social and spatial differentiation.

As for present and future changes in urbanism, these depend in complex ways on demographic, economic, technological and other factors. The twentieth century has witnessed urban growth on an unprecedented scale. 'Megalopolis' and 'conurbation' are new concepts applicable to phenomena of both the western and the non-western world. With increasing globalization, the growing economic and cultural importance of 'world cities' has drawn more attention since the 1980s (Sassen 1991). Yet new modes of transport and communication tend to make human beings less dependent on crowding themselves in limited spaces. 'Counter-urbanization' is thus another modern phenomenon.

civil society

This is an old concept in social and political thought that has recently been revived, especially in eastern Europe but also in the west. Traditionally, up to the eighteenth century, it was a more or less literal translation of the Roman *societas civilis* and, behind that, the Greek *koinónia politiké.* It was synonymous, that is, with the state or 'political society'. When Locke spoke of 'civil government', or Kant of *bürgerliche gesellschaft,* or Rousseau of *état civil,* they all meant simply the state, seen as encompassing—like the Greek *polis*—the whole realm of the political. Civil society was the arena of the politically active citizen. It also carried the sense of a 'civilized' society, one that ordered its relations according to a system of laws rather than the autocratic whim of a despot.

The connection of citizenship with civil society was never entirely lost. It forms part of the association that lends its appeal to more recent revivals of the concept. But there was a decisive innovation in the second half of the eighteenth century that broke the historic equation of civil society and the state. British social thought was especially influential in this. In the writings of John Locke and Tom Paine, Adam Smith and Adam Ferguson, there was elaborated the idea of a sphere of society distinct from the state and with forms and principles of its own. The growth of the new science of political economy—again largely a British achievement—was particularly important in establishing this distinction. Most of these writers continued to use the term civil society in its classical sense, as in Adam Ferguson's *Essay on the History of Civil Society* (1966 [1767]); but what they were in fact doing was making the analytical distinction that was soon to transform the meaning of the concept.

It is to Hegel that we owe the modern meaning of the concept of civil society. In the *Philosophy of Right* (1958 [1821]), civil society is the sphere of ethical life interposed between the family and the state. Following the British economists, Hegel sees the content of civil society as largely determined by the free play of economic forces and individual self-seeking. But civil society also includes social and civic institutions that inhibit and regulate economic life, leading by the ineluctable process of education to the rational life of the state. So the particularity of civil society passes over into the universality of the state.

Marx, though acknowledging his debt to Hegel, narrowed the concept of civil society to make it equivalent simply to the autonomous realm of private property and market

relations. 'The anatomy of civil society', Marx said, 'is to be sought in political economy'. This restriction threatened its usefulness. What need was there for the concept of civil society when the economy or simply 'society'—seen as the effective content of the state and political life generally—supplied its principal terms? In his later writings Marx himself dropped the term, preferring instead the simple dichotomy 'society—state'. Other writers too, and not only those influenced by Marx, found less and less reason to retain the concept of civil society. The 'political society' of Alexis de Tocqueville's *Democracy in America* (1835–40) recalled the earlier sense of civil society as education for citizenship; but Tocqueville's example did little to revive the fortunes of what was increasingly regarded as an outmoded term. In the second half of the nineteenth century 'civil society' fell into disuse.

It was left to Antonio Gramsci, in the writing gathered together as the *Prison Notebooks* (1971 [1929–35]), to rescue the concept in the early part of the twentieth century. Gramsci, while retaining a basic Marxist orientation, went back to Hegel to revitalize the concept. Indeed he went further than Hegel in detaching civil society from the economy and allocating it instead to the state. Civil society is that part of the state concerned not with coercion or formal rule but with the manufacture of consent. It is the sphere of 'cultural polities'. The institutions of civil society are the Church, schools, trade unions, and other organizations through which the ruling class exercises hegemony over society. By the same token it is also the arena where that hegemony is challengeable. In the radical decades of the 1960s and 1970s, it was Gramsci's concept of civil society that found favour with those who attempted to oppose the ruling structures of society not by direct political confrontation but by waging a kind of cultural guerrilla warfare. Culture and education were the spheres where hegemony would be contested, and ended.

New life was also breathed into the concept by the swift-moving changes in central and eastern Europe in the late 1970s and 1980s. Dissidents in the region turned to the concept of civil society as a weapon against the all-encompassing claims of the totalitarian state. The example of Solidarity in Poland suggested a model of opposition and regeneration that avoided suicidal confrontation with the state by building up the institutions of civil society as a 'parallel society'. In the wake of the successful revolutions of 1989 throughout the region, the concept of civil society gained immensely in popularity. To many intellectuals it carried the promise of a privileged route to the post-communist, pluralist society, though they were vague about the details. Western intellectuals too were enthused anew with the concept. For them it suggested a new perspective on old questions of democracy and participation, in societies where these practices seemed to have become moribund.

Civil society, it is clear, has renewed its appeal. As in the eighteenth century, we seem to feel once more the need to define and distinguish a sphere of society that is separate from the state. Citizenship appears to depend for its exercise on active participation in non-state institutions, as the necessary basis for participation in formal political institutions. This was Tocqueville's point about American democracy; it is a lesson that the rest of the world now seems very anxious to take to heart. The question remains whether 'civil society' will simply be a rallying cry and a slogan, or whether it will be given sufficient substance to help in the creation of the concrete institutions needed to realize its goals.

class, social

In the course of the first three decades of the nineteenth century the term class gradually replaced estates, ranks and orders as the major word used to denote divisions within society. The change of vocabulary reflected the diminishing significance of rank and ascribed or inherited qualities in general, and the growing importance of possessions and income among the determinants of the social position. Taken over by social theory from its original context of political debate, class came to refer to large categories of population, distinct from other categories in respect of wealth and related social position, deriving their distinctive status mainly from their location in the production and distribution of social wealth, sharing accordingly in distinctive interests either opposing or complementing other group interests, and consequently displaying a tendency to a group—distinctive political, cultural and social attitudes and behaviour. At the very early stage of the debate, class was given a pronounced economic meaning, arguably under the influence of David Ricardo, who identified the social category of labourers with the economic category of labour, understood as one of the factors of capitalist production. Political economists of the 'Ricardian socialist' school (William Thompson (1824), Thomas Hodgskin (1825) and others) developed Ricardo's suggestions into a comprehensive economic theory of class division, which was then adopted and elaborated

upon by Karl Marx.

The many usages of class in social-scientific theory and research are invariably influenced by Marx's magisterial vision of class division as, simultaneously, the principal source of social dynamics and the main principle of its interpretation. Even if historiosophic aspects of Marx's class theory (all history is a history of class struggle; social change occurs through class revolutions; the conflict between capitalists and workers, arising from the capitalist form of production, is bound to lead to a proletarian revolution and to a new, socialist form of production) are questioned or rejected, the enduring interest in class and, indeed, the unfaltering centrality of the category of class in social-scientific discourse are due to Marx-inspired belief in a high predictive and explanatory value of (primarily economic) class in respect of both individual and collective behaviour.

The resilience to this latter aspect of Marx's theoretical legacy is in no small part due to its overall harmony with the dominant liberal world-view, which interprets individual action as, by and large, rational pursuit of interest, and assigns to 'gain' the role of the central motive of human conduct. The continuous popularity of Marx's class theory has been helped by the incorporation of these tacit premises of common sense and the resulting strategy of interpreting social antagonisms as conflicts of economic interests (that is, incompatibility of goals rationally pursued by various groups differently located within the economic process).

Defining classes as large groups united by their common location within the economic process and aspiring, against efforts of other classes, to an increased share of the surplus product, was a habit firmly established inside the classic political economy before Marx. The fateful contribution of Marx consisted in the reading into the class conflict of another dimension—the struggle for the management of social surplus. Since, within the capitalist order, the right to the surplus was the prerogative of the managers of the productive process, rational effort to amplify a class share in the surplus product must be aimed at the management of production; since, again in the capitalist system, the right to manage productive process as a prerogative of the owners of capital (or means of production), a class barred from access to the surplus can defy its deprivation only through dissociating the right to manage from the right of ownership—through the expropriation of the owners of the capital. In the succession of historical forms of class struggle, the conflict between capitalists and their workers was thus presented by Marx as the modern equivalent of *both* the conflict between pre-capitalist landlords and their serfs *and* the conflict between landowning aristocracy and industry-owning capitalists. Indeed, the specifically Marxist approach to class analysis of industrial society consists in conflating the two dimensions of class conflict and the tendency to interpret the first (the redistribution of surplus) as an immature manifestation, or an early stage, of the second (the management of the production of surplus).

In consequence, the Marx-inspired study of class and class conflict focuses its attention on the combat between owners of capital and industrial workers. More specifically, in this conflict, considered central for the current historical era, this study is interested in the progression of industrial workers from their objective situation as a factor in the process of capitalist production ('class in itself') to the acquisition of a consciousness of their situation and, finally, to the appropriation of a political strategy aimed at radically

overcoming their subordination to capital by abolishing the capitalist mode of production itself ('class for itself').

For the Marx-inspired class theory, therefore, the major difficulty arises from the evident failure of industrial workers to make any notable advance along the line of anticipated progression. A century and a half after the essential historiosophical assumptions of Marx's class theory had been made public in the *Communist Manifesto* (1980 [1848]), the workers of the industrialized world seem to come nowhere near the threshold of the socialist transformation of society. The gap between predictions generated by class theory and the actual tendency of historical development was brought into sharp relief in the wake of the October Revolution in Russia in 1917: a revolution claiming to fulfil the Marxist promise of socialist transformation occurred in a society little advanced in its capitalist development, while all the timid attempts at socialist revolution in truly capitalist countries with a large industrial working population failed. What, from the theoretical perspective, appeared a bewildering incongruity of historical praxis, triggered off recurring attempts among Marxist thinkers to provide auxiliary theories accounting for the failure of the anticipated historical tendency to materialize.

The first, and tone-setter, in the long chain of such auxiliary theories was Lukács's (1967 [1923]) 'false consciousness' theory. Lukács distinguished 'consciousness of class' from 'class consciousness'; the first was the empirically ascertainable state of ideas and motives of the class members arising from the experience accessible within their daily business of life, while the second could be arrived at only through a bird's-eye survey of the total situation of the society, and a rational study of the totality of the information related to the social system (Lukács was here influenced by Weber's method of 'ideal types'). In Lukács's view, there was no automatic passage from the first to the second: the information necessary to construct ideal-typical 'class consciousness' was not available within the individual experience constrained by the tasks of daily survival. The empirical consciousness of class displayed a tendency, therefore, to remain a 'false consciousness', misguided and misled as it were by the narrow horizons of individual experience—unless assisted by scientific analysis filtered into the minds of the workers through the channels of their political organizations. In Lukács's subtle revision of the original model, the passage from 'class in itself to 'class for itself', far from being an automatic process guaranteed by the logic of capitalist economy, has now become a matter of ideological struggle. Without such battle of ideas the passage would not be probable, let alone inevitable.

Numerous suggestions have been made in the sociological literature since the mid-1960s to render the discrepancy between the objective deprivation of the workers, and the apparent lack of radical opposition to the system responsible for it, amenable to empirical study, leading eventually to the location of factors either furthering the persistence of deprivation or prompting opposition to it. An early attempt was made by Dahrendorf (1959) to analyse the problem in terms of the passage from 'quasi-groups', united only by 'latent interests', to 'interest groups', whose Consciousness of the common fate renders their interests 'manifest'. Sharing of latent interests is a necessary, but insufficient, condition of the passage; the latter demands that a number of additional factors must be present. Developing this insight, Morris and Murphy (1966) suggested that class consciousness should be seen as 'a processual emergent', and that from 'no perception of

status difference' to a 'behaviour undertaken on behalf of the stratum interests and ideology' lead a number of stages, each subject to a somewhat different set of factors. In a highly influential collective study of *The Black-Coated Worker,* Lockwood (1958) departed from the 'stages' or 'progression' framework heretofore dominant in post-Marxian study of class consciousness and proposed that depending on the technologically determined type of employment, presence or absence of communal living and other cultural aspects of the mode of life, different types of consciousness ('traditional', 'deferential' or 'privatized') may develop among workers, each acquiring a degree of permanence grounded in its congruence with specific conditions of life. The early study of class consciousness by Parkin (1974) prompted similar conclusions: Parkin singled out, as an attitudinal type most likely to arise from life experience of the workers, a 'subordinate' ideology, taking either a 'deferential' or 'aspirational' form, but in both cases inducing the workers to make peace with the system responsible for their subordinate position.

These auxiliary theories all assume that the life situation of the workers within the capitalist mode of production necessarily produces an anti-capitalist tendency in their consciousness. It is this assumption, and this assumption only, which renders the evident absence of anti-capitalist action problematic and gives both meaning and urgency to the study of factors responsible for the empirical departure from a theoretically grounded expectation.

Not so in the case of another large family of class theories, tracing its origin to Max Weber. Weber revised Marx's theory of class in three important respects. First, having accepted Marx's notion of class as a category articulated first and foremost within the network of economic relations, he denied to these relations the determining role in respect of the articulation of society on its sociocultural and political planes. Status groups (the nearest equivalent of the Marxist idea of class consciousness) as well as political groupings (the nearest equivalent of the Marxist idea of class action) are categories in their own right, parallel to but not necessarily overlapping with economically determined classes, and subject to their own constitutive rules and developmental logic. In short, Weber denied that economic divisions were necessarily mirrored in the cultural and political articulation of the society. Then, having related class, as an economic phenomenon, to the market (specifically, to the chances of access to marketable goods), Weber questioned the possibility of determining *a priori* which of the many conflicts of interests that the market may generate at various times should be assigned a paramount role. And in contrast to Marx, Weber argued that interests vary with respect to different goods and market chances. Consequently they divide the population exposed to the market in more than one way, each individual belonging in principle to a number of classes whose boundaries need not overlap. (The concept of 'housing classes', advanced by Rex (1967), is a good example of a category of economic classes articulated in relation to just one, though highly important, marketable commodity.) The relative importance attached by a given individual to each of the classes to which they belong is not, therefore, determined in advance. It may change, depending on the structure of the market situation, and no one class can be credited in advance with a capacity to command an overwhelming allegiance, displacing all other classes as the major determinant of action.

Weber's insight into the multiplicity of classes and the role of the market in their articulation has been applied, particularly by British sociologists, in a novel analysis of the self-perception of classes and their responses to class inequality. Theoretical models emerging from these analyses refuse to be constrained by the idea of a structurally assigned class consciousness organizing the field of class attitudes and opinions, and instead attempt to gear themselves, with some success, to the empirically accessible evidence of actual ideologies, policies and actions of labour. Among these developments two are perhaps most seminal. One is W.G.Runciman's (1966) concept of 'relative deprivation' (akin to Moore's concept of 'outraged justice'), according to which groups, in their effort to assess their own social position, tend to 'compare with comparable' only: that is, they do not perceive as inequality, at least not as an 'unjust' inequality, the differences between their situation and that of groups distant on the scale of possessions—but they keenly guard their parity with groups they consider their equals, and are goaded into collective action when overtaken by those occupying a lower rung of the ladder. A somewhat similar analysis of class conflicts has been advanced by Parkin (1979) in his later study, drawing on the little used concept of 'closure', introduced but left largely undeveloped by Weber. According to Parkin, the mechanism of class behaviour can best be understood in terms of a tendency to preserve, and if possible enhance, whatever privileged access to coveted market commodities a given class may possess. Subject to this tendency, rational action would consist in the policy of either 'closure by exclusion' (to prevent dilution of the privilege by an influx of those below), or 'closure by usurpation' (to acquire a share in the privileges of those above). In the light of both analyses, organized labour's notorious lack of concern with the extremes of the social distribution of surplus, the paramount importance attached in the practice of trade unions to the preservation of 'differentials', or the puzzling indifference of the same unions to the conditions of the unemployed poor (as distinct from the defence of members' jobs), are all manifestations of a sociological regularity, rather than aberrations calling for special explanations in terms of unusual factors.

The American reception of Weberian ideas pointed in a somewhat different direction. It was guided by the Weberian image of the essential multidimensionality of social differentiation, and was concerned above all with the investigation of correlation (or lack of correlation) between wealth, prestige and influence. In practice most American sociology (particularly until the 1960s) tended to assign a central role to the dimension of prestige (as exemplified by the widespread studies of social deference in relation to occupations). In the context of these practices, however, the term 'class' was employed but rarely (when used outside the Weberian current, for example by Warner or Centers, the term was given a primarily psychological meaning). The specifically American approaches to the question of socially induced inequality are not an exact equivalent (or an alternative to) class theory, and are better analysed in their own framework, as theories of stratification (based on the master-image of gradation, rather than division).

As for class theory proper, both post-Marxian and post-Weberian approaches remain faithful to the ground premises articulated early in the nineteenth century: class is first and foremost an economic phenomenon, and class conflict is above all about the defence or the improvement of economic position, that is, of the share in the distribution of social surplus. One can say that the discursive formation of class has been shaped in its present

form in the period of reinterpretation, in economic terms, of social conflicts spanning the course of west European history between the French Revolution and the 'Spring of Nation' of 1848. It was only quite recently that the rethinking of the class model of society has developed sufficiently to put in question the very premises on which the discourse of class is grounded. One of the important lines of questioning comes from the work of Foucault (1980) which revealed a close association of the modern social system, not so much with the invention of machine technology or the spread of the capitalist form of labour, as with the establishment of a new type of 'disciplinary' power, aimed directly at the control of the human body and using surveillance as its main method. From this perspective the intense social conflicts of the early nineteenth century, later interpreted as manifestations of the inchoate labour movement, are seen as the last stage of the defensive struggle against new forms of controlling power; while the economically oriented organizations of factory workers, portrayed within class theory as specimens of a mature labour movement, are seen as a product of displacing the original conflict, centred around control, on to the field of distribution.

Whatever the view of the applicability of class theory to the understanding of the past two centuries, other doubts are raised about its usefulness in the study of the current stage in social development. Habermas (1978 [1973]), Offé (1964), Gorz (1982) and Touraine (1971) among others drew attention, each in a slightly different way, to the rapidly shrinking size of the industrial labour force, to the diminishing role of bargaining between owners of capital and industrial workers in organizing the distribution of surplus, and to the growing mediation and, indeed, initiative of the state in reproducing the essential conditions of the social production of surplus. In view of these developments, it is increasingly difficult to maintain that class membership remains a major key to the mechanism of reproduction of societally inflicted deprivations (and, more generally, social differentiation as such) or, for that matter, a major explanatory variable in the study of individual and group behaviour. Thus far, however, no alternative concept of similar comprehensiveness and cogency has been proposed to replace class in the description and interpretation of socially produced inequality.

Some sociologists have attempted to replace class as the overriding determinant of identity with other criteria, notably gender, ethnicity, race, or culture. On the whole, however, contemporary sociologists are not inclined to accept that one dimension of stratification subsumes all others. Identity is generally treated as multidimensional, and the ability of individuals to construct and deconstruct their social identities is acknowledged. Indeed, the degree to which this freedom is enjoyed may be seen as the most salient element in defining social status. The wider social categories, previously treated as given, are now also analysed as the products of human agency. Moreover, no principle of division or stratification is believed to apply to all members of a society. The notion of the underclass, for example, tacitly suggests that a part of the population is excluded from the 'class system'.

classical economics

The term classical economics, although sometimes given the rather broader meaning of any economics which is not Keynesian, is generally taken to refer to the body of economic ideas stemming from the work of David Hume, whose most important work was published in 1752, and Adam Smith, whose great *Wealth of Nations* was published in 1776. These ideas came to dominate economics particularly, but far from exclusively, in Britain throughout the last quarter of the eighteenth and the first three quarters of the nineteenth century.

Hume's contributions principally concerned money and the balance of payments. But Smith's work is a virtual compendium of economics, focusing on the key question of economic growth, and covering division of labour, distribution, capital accumulation, trade and colonial policy, and public finance. Among their successors was T.R.Malthus; though chiefly famous for his writings on population, he covered the whole field of economic inquiry (Malthus 1820). A major impetus to the development of classical economics was provided by David Ricardo (1951–73). He read Smith's work critically and from it constructed a 'model' which, unlike Smith's work, produced fairly clear and definite predictions. Ricardo succeeded initially in attracting disciples, notably J.Mill (1821–6; see also Winch 1966) and—though he later drifted away from Ricardo's influence—J.R.McCulloch (1825) as well as Thomas De Quincey. But his influence waned after his death and the work of J.Mill's son, J.S.Mill (1848; 1963–85), is much closer to Smith in range, reliance upon empirical material, and the avoidance of precise predictions.

Classical economics covered the whole field of economic enquiry, but with an emphasis on questions dealing with large aggregates—economic growth, international trade, monetary economics and public finance—rather than with the analysis of the behaviour of the maximizing individual which came to be of dominant interest after 1870. (In the field of value theory, in particular, the classical economists generally made do with various sorts of production theories emphasizing, in varying degrees, the importance of labour cost in total cost.) At the same time a fundamental premise lying behind the analysis of aggregates, and stemming from Smith, was that individuals were motivated by the pursuit of self-interest, and that their pursuit had to be limited by a framework of law, religion and custom, to ensure coincidence of private and social interest. This in turn meant that in the field of economic policy classical economics, while predisposed against government interference (partly because of the way in which such interference could be used for purely sectional interest, and partly because of a belief that decentralized individual knowledge was superior to state knowledge), was pragmatic— the necessary legislative framework could be learned only by experience and enquiry.

At the heart of the classical vision is the idea of economic growth occurring through the interaction of capital accumulation and division of Labour. Capital accumulation made it possible to postpone the sale of output, permitting the development of

specialization and division of labour. Division of labour in turn increased total output, permitting further capital accumulation. Economic growth would be increased by allowing capital to flow to where it was most productive; thus, other things being equal, it was desirable to remove restraints on the free allocation of resources. Division of labour itself was limited by the extent of the market. The extent of the home market depended on population and income per head. As capital was accumulated, the available labour supply found itself in greater demand and wages rose above the necessary minimum— 'subsistence' which could be either psychological or physiological. Population responded to the rise in wages by increasing; this in turn increased the labour supply which pushed wages back towards subsistence, though, if subsistence was a psychological variable—as it was with many classical writers—population growth might well stop before wages had fallen to the old level of subsistence. As wages rose, profits fell; this might check capital accumulation, but as long as profits were above a necessary minimum, capital accumulation would continue. Output, population, and capital thus all grew together. However, a brake on growth was provided by the shortage of a third input, land. With the progress of economic growth, food became more and more expensive to produce, while landlords enjoyed the benefit of an unearned rent arising from ownership of this scarce but vital resource—this aspect was particularly stressed by Malthus and Ricardo. The rising cost of food also meant that the floor below which subsistence could not fall—the minimum wage necessary to procure basic physical necessities of life—rose; and Ricardo in particular emphasized that such a rise would depress profits and might eventually stop capital accumulation and growth altogether. (Smith had believed that growth would stop only when investment opportunities were exhausted.) He then argued that repeal of the Corn Laws (restricting food imports) was urgent, since subsistence could be obtained more cheaply abroad. (Later classical economists such as McCulloch and J.S.Mill were, however, optimistic about technical progress in agriculture which could postpone any slowdown in economic growth by lowering the cost of agricultural output.)

The argument for repeal of the Corn Laws provided one part of a general classical case for freedom of trade; the desire to widen the market to maximize possible division of labour provided another. However, a more general and sophisticated argument for freedom of trade was provided by R.Torrens (1820; 1821) and Ricardo, in the form of the theory of comparative costs (later refined and developed by J.S.Mill) which showed that a country could gain from importing even those commodities in which it had a competitive advantage if it had an even greater competitive advantage in the production of other commodities—it should concentrate its scarce resources on the latter.

Balance of payments equilibrium was ensured by a mechanism which was due to David Hume, and which was also basic to classical monetary theory, the price-specie-flow mechanism. A balance of payments deficit would, through gold outflow, reduce the money supply, and thus the price level, making exports competitive and imports less attractive, and this equilibrating mechanism would continue until the gold outflow stopped and payments came into balance. The price level was thus dependent on the money supply; and the predominant classical view from Ricardo to Lord Overstone (1837) was that the note issue, as part of the money supply, should be contracted if gold was flowing out, since the outflow was a symptom of a price level which was too high. Monetary control was also necessary to dampen the effects of an endogenous trade cycle,

an element introduced into classical economics, chiefly by Overstone, from the late 1830s. (A minority of classical economists, however, viewed the money supply as demand-determined.)

Classical economics represented a major intellectual achievement. The foundations which it laid in the fields of monetary and trade theory, in particular, are still with economics. Eventually it lost some of its momentum; it was always policy-oriented, and as the policy questions were settled—usually along the lines indicated by the classical analyses—and as economists came to take continuing economic growth for granted, they turned their attention to different questions requiring different techniques of analysis.

clinical psychology

Clinical psychology is one of the speciality areas of applied psychology, together with such other specialities as industrial, physiological, measurement and developmental psychology. The science and profession of clinical psychology, as one of the mental health disciplines, utilizes the principles of psychology to understand, diagnose and treat psychological problems; to teach and train students in these principles and their applications; and to conduct research in human behaviour as well as function as consumer of research advances as a means of upgrading the delivery of health care.

The two world wars and the major development of public schools in the USA between the wars vastly accelerated the growth of clinical psychology, first as purely a psychological or 'mental' test application in assessing intellectual and other psychological responses and capabilities, and then, after the Second World War, expanding into other roles, in the psychotherapies as well as in research and training and in formal graduate programmes in clinical psychology. In the USA alone, it has been estimated that during the Second World War 16 million military candidates and recruits were given psychological tests for classification and assignment to duties. In the First World War psychologists did psychometric assessment only; in the Second World War they also carried out treatment responsibilities for mentally ill personnel, together with psychiatrists, social workers, nurses and technicians.

Two major developments after the Second World War furthered the growth of clinical psychology in the USA: the establishment of the National Institute of Mental Health and its support for training and research; and the decision of the Veterans Administration to fund training for clinical psychology as one of the disciplines in mental health to assess and treat veterans with psychological illness. There followed the accreditation, by the American Psychological Association (APA), of doctoral training programmes (over 190 in 1993) and internship programmes (over 435 in 1993) in professional psychology (clinical, counselling, school and professional-scientific psychology); and certification and licensing by states.

Two other standards organizations developed, the first in 1947 and thus growing during the great 'spurt' since the early 1950s, and the second initially an outgrowth of the former. The American Board of Professional Psychology (ABPP) was established in 1947 by the Council of Representatives of the American Psychological Association 'to define the standards, conduct examinations, grant diplomas, and encourage the pursuit of excellence in professional psychology' (1980). The five fields of specialization are clinical; counselling; industrial and organizational; school; and neuropsychology.

In 1957, there were 15,545 life members, fellows and associates in the APA, of whom 1,907 fellows and associates were in the Division of Clinical Psychology. By 1993 there were over 113,000 fellows, members and associates, nearly 13,000 of whom were in the Division of Clinical Psychology or in closely related divisions. There are nearly 16,000 registrants in the National Register.

Clinical psychology has moved towards a reintegration with other fields of psychology; new specialities have also been created within clinical psychology. Health psychology has drawn to it scientists and professionals from other domains of psychology, principally clinical, social, physiological and learning or cognitive areas. This field was initially a research area and increasingly has become an applied field. An interesting cycle in the history of clinical psychology concerns psychological or 'mental' tests, which have played a prominent role in development of clinical psychology since the end of the nineteenth century. After the Second World War, primarily in the USA, graduate programmes decreased their commitment to teaching assessment methods, and their graduates increasingly turned to psychotherapy as a principal activity. Then, research training support, litigation over the effects upon individuals of toxic and other industrial and environmental pollutants, and mounting interest in psychological changes in disease and accident victims and in elderly people all contributed to bringing assessment again into prominence, especially neuropsychological assessment; there are now local, state, regional, national and international societies of neuropsychologists.

cliometrics

The term cliometrics (a neologism linking the concept of measurement to the muse of history) was apparently coined at Purdue University, Indiana, USA, in the late 1950s. Originally applied to the study of economic history as undertaken by scholars trained as economists (and also called, by its practitioners and others, the new economic history, econometric history and quantitative economic history), more recently cliometrics has been applied to a broader range of historical studies (including the new political history, the new social history, and, most inclusively, social science history).

The historians' early interest in cliometrics partly reflects the impact of two important works in US economic history. The detailed estimates by Conrad and Meyer (1958) of the profitability of slavery before the Civil War and the quantitative evaluation of the role

of the railways in economic growth by Fogel (1964) triggered wide-ranging debate, with much attention to questions of method as well as substance. While these two works, combining economic theory and quantitative analysis, attracted the most attention, other books and articles published at about the same time also highlighted the quantitative aspect, although in a more traditional (and less controversial) manner. A National Bureau of Economic Research (NBER 1960) conference volume, edited by Parker, presented a number of important studies (by, among others, Easterlin, Gallman, Lebergott, and North) pushing back many important times-series on economic variables to the early nineteenth century, an effort complemented by the publication, several years later, of another NBER (1966) conference dealing mainly with nineteenth-century economic change. North (1961) combined his new estimates of pre-1860 foreign trade with a familiar regional approach to describe the basic contours of US economic growth from 1790 to the Civil War. These works had important implications for discussions of economic growth in the USA, particularly in the period before the Civil War. The concentration of major publications within a short time period, together with the start of an annual conference of cliometricians at Purdue University, organized by Davis, Hughes, and others, which, with several changes of venue, still continues, generated the momentum which led to major shifts in the nature of the writing of US economic history, as well as revisions of many interpretations of past developments. The late 1950s and 1960s saw similar changes in other subfields of history, particularly political and social history, although it was in economic history that the concentration on theory, quantitative data, and statistical methods was most complete.

In perhaps the most controversial work of cliometrics, Fogel (who was, with North, to win the Nobel Prize in Economics for 1993) co-authored, with Engerman, a work on the economics of US slavery, *Time on the Cross* (1974) whose conclusions as to the profitability, viability and efficiency of slavery triggered considerable debate among cliometricians and other historians. Fogel's subsequent work on slavery, *Without Consent or Contract* (1989) did not lead to a similar debate, although the basic conclusions were similar to those of the earlier work. The 1970s and 1980s saw a broadening of the interests of cliometricians from those of the earlier decades. For example, there was considerable attention given to the study of demographic and anthropometric issues, while North (see, e.g. Davis and North 1971; North 1990), and various other scholars, focused attention on the study of the development of economic institutions and organizations. An indicator of these expanding horizons is seen in the third of the NBER (1986) volumes dealing with economic history, edited by Engerman and Gallman.

The most general characteristics of cliometric work (in economic history) have been the systematic use of economic theory and its concepts to examine economic growth in the past, and the widespread preparation and formal statistical analysis of quantitative material. While none of this may seem to provide a new approach in historical studies (as is often pointed out in criticizing claims of novelty), the more explicit attention to theory and the more frequent reliance on quantitative materials and statistical procedures have had an important impact upon the manner in which historical questions have been approached and interpreted. However, cliometricians still differ in how they make use of quantitative and statistical methods. To some, the major work is the preparation of quantitative data, either of detailed information for a particular time period (based on, e.g.

the samples of population, agriculture, and manufacturing records drawn from the decadal federal census) or of long-period time-series (e.g. national income and wealth, wages, labour force) to be used in measuring and understanding past economic changes. These estimates require imaginative reconstructions from the available samples of past data, but do not often involve sophisticated statistical tools. Others emphasize the use of more formal statistical methods, most frequently regression analysis, to test hypotheses. Some cliometricians restrict themselves to the use of economic theory to analyse institutional and economic changes, which are difficult to describe quantitatively.

Continued interest in economic (and political and sociological) theory has led to a more frequent attempt to find historical generalizations based upon social science concepts and methods than some, more traditionally trained, historians seem comfortable with. Nevertheless, the ability to collect and examine data, from archival and published sources, furthered by the development of the computer, has permitted a considerable expansion in the amount of material relevant to questions of interest to historians, as well as better methods of organizing, analysing, and testing data. The heat of earlier debates on method has apparently declined as the use of quantitative methods and theoretical constructs has become a part of the standard tool-kit of historians, while cliometricians have broadened the range of questions they have discussed and the varieties of evidence utilized.

While the first cliometric studies were done principally by North American scholars and, for reasons of data availability, most frequently concerned the USA in the nineteenth century, since the mid-1970s the temporal and geographic scope has widened, as have the types of questions to which cliometric analysis is applied. Much work has been done on the colonial period, as well as the twentieth century, in the USA. Not only have the interests of American cliometricians expanded to include studies of other parts of the world, but also cliometric work has developed in a number of other countries, most particularly in Britain and other parts of western Europe. Although, as with most attempts at categorization, a sharp dividing line is often difficult to draw, cliometric history continues to emphasize the systematic application of social science theory and the use of quantitative data and statistical analysis to understand the historical past.

cognitive-behavioural therapy

Cognitive-behavioural interventions preserve the demonstrated efficiencies of behavioural therapy within a less doctrinaire context by incorporating the congitive activities of the client in the efforts to produce therapeutic change (Kendall and Hollon 1979). It is a major force in psychotherapy today, both in theory and in application.

Basic to the cognitive-behavioural approach is a set of principles captured briefly as follows. Client and therapist work together to evaluate problems and generate solutions (e.g. collaborative empiricism). Most human learning is cognitively mediated. Cognition, affect and behaviour are causally interrelated. Attitudes, expectancies, attributions and other cognitive activities are central in producing, predicting and understanding behaviour and the effects of therapy. Cognitive processes can be integrated into behavioural paradigms, and it is possible and desirable to combine cognitive treatment strategies with enactive and contingency management techniques (Kendall *et al.,* Mahoney 1977).

Within the boundaries of these fundamental principles, the actual implementation of the cognitive-behavioural therapies varies. The major strategies within cognitive-behavioural therapy include cognitive-behavioural therapy of depression; rational-emotive therapy; systematic rational restructuring; stress inoculation; cognitive-behavioural training with children.

Cognitive-behavioural therapy of depression (Beck *et al.* 1979) is structured, active and typically time-limited. Learning experiences are designed to teach clients to monitor their negative thinking, to examine the evidence for and against their distorted (negative) thinking, to substitute more reality-oriented interpretations for negative thinking, and to begin to alter the dysfunctional beliefs and lifestyle associated with negative thinking. Behavioural strategies such as self-monitoring of mood, activity scheduling, graduated task assignments, and role-playing exercises are integrated with more cognitive procedures such as focusing on changing negative thinking, reattribution, and decentring.

Rational-emotive therapy (RET) offers both a theoretical and therapeutic system consistent with cognitive-behavioural therapy (Ellis 1980). In RET, events do not cause emotional and behavioural consequences; private beliefs do. When the individual's beliefs (salient assumptions) are inaccurate/irrational and are framed in absolutistic or imperative terms, maladjustment is likely to result. RET teaches clients to identify and change the illogical notions that underlie their distressing symptoms.

Systematic rational restructing (SRR) is a derivative of RET which offers a clear description of the procedures of treatment. SRR offers specific techniques for modifying anxiety and irrational beliefs and is implemented in four stages: presenting the rationale for the treatment to the clients; reviewing the irrationality of certain types of beliefs and assumptions; analysing the client's problems in terms of irrational thinking and undesirable self-talk; and teaching the client to modify self-talk and irrationality (e.g. Goldfried 1979).

Stress inoculation (Meichenbaum 1985) is a three-stage intervention which focuses on teaching cognitive and behavioural skills for coping with stressful situations. In the first, educational, phase, clients are taught a conceptual framework for understanding stress in cognitive terms. The second phase, skills training, teaches clients cognitive (imagery, changing irrational self-talk) and behavioural (relaxation, breathing) skills. In the final stage, clients practise the new skills in stressful situations.

Cognitive-behavioural training with children is designed to teach thinking skills (Kendall 1993; Kendall and Braswell 1993). For example, children who lack foresight and planning (e.g. impulsive, uncontrolled, hyperactive/attention disorder) are exposed to training procedures that involve the rehearsal of overt, then covert, self-guiding

verbalizations. Using tasks and role-plays, the therapist and child practise thinking out loud.

Cognitive-behavioural therapies are consistent with therapeutic integration, where varying resources are tapped as sources of effective treatment. In one sense they are prototypical of integration: performance-based behavioural treatments with a focus on the cognitive representation, or meanings, of events and the merits of thinking; in other words, the purposeful interface of thought and action in psychotherapy.

cognitive psychology

According to Drever's (1964) *Dictionary of Psychology,* 'cognition' is 'a general term covering all the various modes of knowing—perceiving, imagining, conceiving, judging, reasoning'. It picks out those forms of abstract thinking and problem solving that are based upon the manipulation of either linguistic symbols (propositions) or iconic symbols (images). Cognitive psychology refers to the attempt to understand these various human faculties by means of systematic empirical observation and theory construction. Its

origins lie in research conducted during the 1950s by Donald Broadbent, Jerome Bruner and George Miller (see Gardner 1985), although it was probably first generally acknowledged as a distinctive intellectual development with the publication of Ulric Neisser's (1967) book, *Cognitive Psychology*. It was also encouraged by cognate movements in other areas of psychology, such as the work by Jean Piaget and David Ausubel in developmental psychology and by Alan Newell and Herbert Simon in artificial intelligence. Cognitive psychology has in turn promoted developments in related areas of psychological research, of which cognitive neuropsychology is a notable example, and it is a central pillar of cognitive science.

The methods and theories of cognitive psychology have been influenced by two rather different traditions. First, cognitive psychology is the natural heir to what used to be called 'human experimental psychology', and it has incorporated (perhaps too uncritically) the behaviourist methodology which dominated psychological research earlier in the twentieth century. It therefore involves most typically the objective description of human behaviour within formal laboratory experiments. These experiments usually seek to differentiate well-articulated theoretical alternatives within an established (though relatively narrow) research paradigm. This approach encourages a degree of artificiality in cognitive research, as it has always been recognized that the degree of naturalism in a laboratory study is likely to be inversely related to the extent to which the subjects' performance can be adequately described and to which the task itself can be conceptually analysed.

Cognitive psychology also stems from the field of human factors research which developed during the Second World War in order to tackle problems concerning human-machine interaction. This work led to an interest in the control mechanisms governing intelligent behaviour, to the idea of human thought and action as consisting of discrete stages of information processing, and inevitably to the use of the structure and function of the digital computer as a metaphor in theorizing about human cognition. (This is, of course, distinct from the use of the digital computer itself as a research tool.) An early though highly influential account of such notions was contained in Miller *et al.*'s (1960) *Plans and the Structure of Human Behavior*. Research carried out within this tradition is rather more pragmatic in its orientation: it aims to produce general frameworks which are of direct benefit in the design and construction of complex systems but which may not be amenable to rigorous experimental evaluation (Reason 1987).

Human cognition is undoubtedly a complex object of study, and researchers within cognitive psychology are faced with a number of options with regard to the most fruitful way to conduct their investigations. Eysenck (1984) identified three such decisions: the pursuit of basic or applied research; the focus upon general or specific problems; and the inclusion or exclusion of the motivational and emotional states of the subjects from their domain of analysis. Eysenck observed that the contemporary emphasis was upon 'basic research into specific problems that is conducted with a total disregard for emotional and motivational factors', although he for one has certainly been concerned to address issues concerning the role of emotional and motivational factors in human cognition.

Cognitive psychology does provide sophisticated theoretical accounts based upon experimental manipulations and procedures which have been extensively employed in laboratory-based research. However, there are various respects in which it has proved

difficult to relate such research to practical issues, and Eysenck (1984) pointed to three interrelated problems. First, what is studied in laboratory research may be of little relevance to ordinary human functioning; second, laboratory research has very often ignored important characteristics of the cognition of everyday life; and third, at least some laboratory findings may not extrapolate to real-life events because of the artificiality of the experimental situation. Eysenck pointed out that the goal of laboratory-based research was not simply to mimic aspects of everyday cognitive functioning, but he concluded that genuine theoretical progress in cognitive psychology would be achieved only by means of a cross-fertilization between laboratory studies and more applied research.

Accounts of this sort given by cognitive psychologists themselves tend to assume that it is simply an empirical matter whether the cognitive processes that are being tapped in a particular psychological experiment are actually employed in the everyday task which the experiment is intended to model. Such an assumption is often made when the methods of cognitive psychology are criticized for their dubious 'ecological validity' (to use the prevalent jargon), for the latter tends to be regarded as a purely technical characteristic of particular experimental procedures. Whether or not a psychological experiment involves cognitive processes that are used in everyday life is then a matter to be settled by further empirical research. For instance, Yuille (1986) argued that laboratory-based research revealed little or nothing about the real-life functions of basic cognitive processes, but his criticisms of a purely experimental approach to the study of human cognition were based predominantly upon evidence obtained from formal laboratory experiments.

However, more radical critics have argued that the social situation of the psychological experiment is qualitatively different from the concrete tasks that confront individual human beings in their everyday lives. It is this point which is behind criticisms of the artificiality and worthlessness of laboratory experiments (Harré 1974). Some critics have pointed to the power relationships inherent in the experimental situation, and have put forward political and moral arguments concerning the effects of laboratory research upon both subjects and researchers (Heron 1981). Rowan (1981) suggested that experimental laboratory work exemplified the various forms of alienation which according to Marx would operate in any economic system where the workers (in this case, the subjects) did not own the means of production. There is thus perhaps a perverse sense in which laboratory experiments successfully (though unwittingly) capture certain aspects of the social situation of workplace, though certainly not of those situations in which individual human beings engage in autonomous and self-motivated cognition. Nevertheless, on this account, to compare the results of laboratory-based research either with the findings of applied studies or with 'natural history' observations would simply fail to set like against like (though Rowan included conventional forms of 'applied' research in his criticisms).

These criticisms are not trivial ones, and some call into question the whole enterprise of cognitive psychology. They clearly need to be addressed, perhaps by means of more sophisticated conceptual analyses, perhaps by means of theoretical developments, or perhaps by means of methodological innovations. However, many of these criticisms are already being addressed, and this in itself has led to significant advances within the field of cognitive psychology. In addition to the concern with practical applications which has always been inherent in the human factors tradition, the 1970s and 1980s saw a lively

interest in accommodating mainstream research to the realities of everyday life, most obviously with regard to research on human memory (Gruneberg *et al.* 1978; 1988). Nowadays, most cognitive psychologists would agree that attention to the potential or actual applications of research is likely to provide a major impetus in the development and elaboration of theories and research within cognitive psychology itself.

cognitive science

The term cognitive science refers to the interdisciplinary study of information processing in human cognition. Although there are obvious precursors in the work of mathematicians such as Alan Turing and John von Neumann, of neurophysiologists such as Warren McCulloch and Walter Pitts, and of communications theorists such as Norbert Wiener and Claude Shannon, it is generally agreed that cognitive science came into being in 1956. This year marked the beginnings of genuine collaboration among research workers in artificial intelligence (Allen Newell and Herbert Simon), cognitive psychology (Jerome Bruner and George Miller), and linguistics (Noam Chomsky); Gardner (1985) has identified cognate movements in epistemology, anthropology, and the neurosciences. Kosslyn (1983) has summarized the manner in which cognitive science has taken advantage of developments in these different disciplines:

> From computer science it draws information about how computers and computer programs work; from philosophy it has adopted not only many of its basic questions and a general orientation toward the mind, but many of the fundamental ideas about information representation (e.g. 'propositions'); from linguistics it draws a basic way of thinking about mental events and theories of language; and from cognitive psychology it draws methodologies and specific findings about human information-processing abilities.

Cognitive science has been inspired very much by insights within the discipline of psychology, and in particular has developed in step with the field of cognitive psychology. However, it is intrinsically at odds with much of mainstream cognitive psychology, which grew out of what used to be called 'human experimental psychology', and which has incorporated the behaviourist methodology which dominated research earlier this century. Cognitive science owes rather more to the 'human factors' tradition within cognitive psychology, which developed during the Second World War in order to tackle problems concerning human-machine interaction. An illustration of the disparity between cognitive psychologists and cognitive scientists arises in their attitudes to introspective reports of conscious experience. Cognitive psychologists tend to be suspicious of introspective reports and sceptical of their value as empirical data, whereas in cognitive science the use and analysis of such verbal 'protocols' is widely accepted (see, e.g. Ericsson and Simon 1984). As an excellent case study within the field of cognitive science, Kosslyn (1983) has given an autobiographical account of his work on mental imagery, which combines systematic experimentation with introspectionist methodology.

Gardner (1985) has identified two core assumptions in contemporary research in cognitive science. The first assumption is that to explain intelligent behaviour it is necessary to incorporate the idea of 'internal' or 'mental' representations as a distinctive

and irreducible level of theoretical analysis. Indeed, theories in cognitive science are often based upon the structuralist notion that internal representations intervene between experience and behaviour. Human cognition is regarded as the symbolic manipulation of stored information, and in order to understand intelligent human behaviour, it is necessary to investigate the properties of these internal representations and of the processes that operate upon them. Nevertheless, it should be noted that sociologists have argued that descriptions of mental experience are socially constructed and are at the very least problematic as explanations of behaviour (see Woolgar 1987).

The second core assumption is that the computer is a useful model of human thought and a valuable research tool. Precisely because digital computers are artefactual systems that have been specifically designed for the symbolic manipulation of stored information, the language of computer science seems to provide a convenient and congenial means of articulating notions concerning human cognition. As Kosslyn (1983) has noted, cognitive scientists have therefore borrowed much of the vocabulary that was originally developed to talk about computer functioning and use it to talk about mental representation and processing in human beings. Indeed, the language of computer science tends to function as a theoretical *lingua franca* among the variety of disciplines that make up cognitive science; as Levy (1987) has put it, the computational representation of models is the 'common test-bed' of cognitive science. Of course, the contemporary digital computer may not provide the best model for characterizing human information processing, and alternative system architectures may prove to be more useful (Kosslyn 1983): a very fashionable approach based upon the notion of parallel distributed processing is claimed to be much more appropriate for modelling human cognition because it is more akin to the known physiology of the central nervous system (McClelland *et al.* 1986). Nevertheless, the supposed functional similarity between computers and human brains provides a distinctive means of evaluating the theories of cognitive science: the computer simulation of behaviour. The point has been elegantly summarized by Kosslyn (1983):

> If the brain and computer both can be described as manipulating symbols in the same way, then a good theory of mental events should be able to be translated into a computer program, and if the theory is correct, then the program should lead the computer to produce the same overt responses that a person would in various circumstances.

A fundamental criticism of research in cognitive science is that it has tended to view cognition in abstract terms, devoid of any personal, social or ecological significance. As Gardner (1985) remarks, cognitive science tends to exclude (or at least to de-emphasize) 'the influence of affective factors or emotions, the contribution of historical and cultural factors, and the role of the background context in which particular actions or thoughts occur'. Gardner implies that this feature of cognitive science is the result of a deliberate strategic decision in order to render the problems under investigation more tractable. However, it has to be recognized that the pattern of much research within cognitive science (as in other areas of scholarly investigation) is set by existing traditions, and therefore such strategic choices have typically gone by default. The relevance of cognitive science to everyday human experience and its practical application in real-life

situations will undoubtedly be enhanced by the incorporation of emotional, cultural and contextual factors into theoretical accounts of human cognition.

cohort analysis

Cohort analysis (also known as longitudinal analysis) refers to studies that measure characteristics of cohorts through their lives, a cohort being a group of persons who have experienced the same life event during a specified period of time (normally one year). If the life event is birth, one speaks of a birth cohort, or generation. Similarly one may speak of marriage cohorts, divorce cohorts, educational cohorts, etc., life events in these cases being respectively marriage, divorce, or the attainment of a certain level of education, during a particular period of time. For instance one may follow a cohort of marriages over time in order to ascertain how many couples eventually divorce, and to determine the risk of divorcing at each duration of marriage.

Cohort data are usually obtained by comparing the characteristics of a cohort at two or more points in time, using census or sample survey data. When the *same* individuals are compared, the term 'panel study' is often used. Demographic and epidemiological data on cohorts can frequently be derived from records or registers, such as vital statistics or cancer registers. Other important sources of cohort data are retrospective studies, in which respondents are asked to provide information about past characteristics and events.

Cohort data may be affected by selection effects. People die, or move, between censuses or surveys, and retrospective questions can be answered only by those who survive. Bias may be introduced if those who are lost tend to have other characteristics that differentiate them from those interviewed. Retrospective studies are also influenced by recall lapses.

Cohort measures may relate to the characteristics of the cohort, or to events experienced by it. For example, an inter-cohort study might compare the proportions of single people in different cohorts, or focusing on birth, compare the average number of children borne by women at the end of their reproductive period. An intra-cohort study would be concerned rather with changes in characteristics over a lifetime, or in the distribution of events by age, such as changes in the proportion surviving by age, or the distribution of deaths or risks of dying by age.

Cohort studies are often undertaken in order to distinguish cohort effects (i.e. effects particular to each cohort) from age (or duration) effects and period effects. Ordinary statistical methods are unsatisfactory here, due to the *identification problem.* Age, period and cohort (APC) are not independent variables: knowing two yields the third. The three variables cannot therefore be used simultaneously in statistical procedures that require linear independence between variables. One way out of this difficulty is to place constraints on the model, for example to suppose that one of the effects (e.g. the period effect) is nil, or that the effect of being in one age group is a particular constant. APC models, moreover, do not usually incorporate terms measuring interaction effects between age and cohort, or between period and cohort. Alternatively, the period variable (such as the year), may be used as an indicator of an underlying variable, for example, yearly income per head. If data are available, one may then substitute the underlying variable for the year. This is a simple resolution of the identification problem, as the underlying variable is not a linear construct of age and cohort. The choice of the procedure or constraint must rest on supplementary information, or on an appeal to theoretical considerations: it cannot be made on purely statistical grounds.

collective action

Unlike rational individuals who act to fulfil their own self-interest, a group of rational actors may not engage in collective action to pursue a common interest. Groups often value collective or public goods that are available, once they are produced, to contributors and non-contributors alike. As people can potentially receive the benefits of these collective goods without paying for them, they will not readily contribute to their provision.

The logic of collective action (Olson 1965), which has proved applicable to a remarkably broad range of social and economic situations, proceeds from the assumption that co-operation must be explained in terms of the individual's cost-benefit calculus rather than the group's, because the group is not itself rational, but can only consist of rational individuals. In the classic examples of collective action problems, such as preserving the environment, sharing a common natural resource, participating in national defence, voting in mass elections, and engaging in social protests, group members gain when all individuals do their share, but the marginal benefit of a single contribution is outweighed by its cost. What is best for the group therefore is not necessarily best for the individual. The study of collective action using laboratory experiments, game theory, and historical cases has tried to identify the conditions under which rational actors are likely to co-operate when they have a strong incentive to be free riders.

The collective action problem is most often represented by a game theoretic model known as the prisoners' dilemma (Hardin 1982). The prisoners' dilemma is a non-co-operative game in which the players' choices are independent and agreements and promises cannot be enforced. A group of n individuals must decide to contribute (i.e. co-operate) or not to contribute to a collective good (i.e. defect). Depending on whether the public good is divisible, the utility of a contribution is either the additional amount of the good that is produced or it is the increase in the probability that an indivisible public good will be generated as a result of the contribution. Unanimous co-operation is preferred by everyone to unanimous defection, but the payoff structure of the game also specifies that no matter how many individuals contribute, each person does better by defecting and thereby enjoying the public good for free; in this sense, defection is a dominant strategy. However, should each rational individual choose his or her dominant strategy, the outcome—total defection—is Pareto-suboptimal, for everyone can improve his or her position if all co-operate in the supply of the public good.

A group may succeed in providing itself with some amount of the public good if it is 'privileged'; that is, if it contains a single member who receives a sufficiently large benefit from the good that it is economical for the person to pay for it even if no one else contributes. In Mancur Olson's (1965) terminology, this results in the exploitation of the great by the small. Groups that are not privileged have to devise other means to encourage contributions, either by changing the incentive structure facing individuals, or by inducing co-operative behavior through repeated social interaction.

Many groups alter cost-benefit calculations by offering selective incentives in the form of rewards to co-operators and punishments to free riders. Members of professional organizations, for example, receive trade publications and journals, reduced fare travel packages, subsidized health insurance programmes, and other products or services. Shame, praise, honour and ostracism can likewise be viewed, in this regard, as non-material social selective incentives. The provision of selective incentives, however, usually entails a separate collective action problem that demands its own explanation, as successful organization for collective ends characteristically precedes the provision of selective incentives to members.

Another potential selective incentive is the benefit inherent in the activity itself, in which case the motivation behind co-operation is not the outcome sought by collective action, but the process or experience of participation (Hirschman 1982). It is undeniable that, for some people, political and organizational activity builds self-esteem and feelings of political efficacy, symbolizes political citizenship, reinforces moral convictions, and constitutes an enthralling experience. The non-instrumental nature of these motives, however, makes them problematic in theories of instrumental rational action.

Aside from changing the incentive structure of the prisoners' dilemma (thus removing the dilemma), co-operation in groups can be fostered, in the absence of selective incentives, by repeated social interactions that introduce long-term calculations (Taylor 1987). In iterated social interaction, a person can try to influence the behaviour of others by making his or her choices contingent upon their earlier choices. In a two-person prisoners' dilemma, for example, a person might co-operate on the first exchange and thereafter co-operate only if the other player co-operated on the previous exchange. If both players use this strategy—known as tit for tat—mutual co-operation will be the equilibrium outcome as long as future benefits are not discounted too heavily. Co-operation is therefore possible among self-interested players if they care sufficiently about future payoffs to modify their present behaviour.

Ongoing social interaction is less likely to solve the collective action problem when the group is large because defection is harder to identify and to deter when many people are involved. One possible equilibrium in the n-person prisoners' dilemma occurs when everyone co-operates initially and continues to do so as long as everyone else does, but not otherwise. Co-operation is therefore sustained by the expectation that, as soon as one person defects, everyone else defects in retaliation. A less stringent equilibrium occurs when there is a subset of co-operators, some proportion of which co-operates contingent upon the co-operation of every other member of the subset. These equilibria, how-ever, may be difficult to realize in practice if threats of disbanding given a single or a small number of defectors are not credible. Such is the case, for example, when the remaining co-operators can still profitably produce the collective good, so that they would have to hurt themselves in order to punish free riders. Incredible threats open the door to mass defection: if some individuals free ride on the assumption that others will continue to provide the collective good, then everybody might be so tempted and the collective good may never be produced.

For this reason, contingent co-operation in large-scale ventures is facilitated when collective action comprises a federated network of community groups and organizations. Monitoring is feasible in these smaller groups and co-operation or defection can be

rewarded or punished in the course of everyday interaction with friends and associates. Consequently, individuals who refuse to contribute to a community-wide effort may suffer damage to their reputations and lose companionship and future opportunities for beneficial exchanges with those in their immediate reference groups (Chong 1991).

There is no reason to suppose that successful collective action will be driven by a single motivation, either coercive or voluntary. Self-interested calculations based on selective material incentives and ongoing social exchange often have to be supplemented by moral and psychological considerations in order for people to contribute to collective goods. Nor is it necessary to assume that all contributors to collective action will employ the same cost-benefit calculus. Collective action frequently relies on the initiative of committed leaders who supply information, resources and monitoring, and lay the foundation for subsequent conditional co-operation among more narrowly self-interested actors.

colonialism

When most of the world's colonial dependencies attained independence as sovereign nation-states in the middle of the twentieth century, it seemed that an epoch had ended logically as well as historically. Colonies had been particular forms of imperialism, created during the tide of western European expansion into other continents and oceans from the sixteenth century onwards. At high noon—the end of the nineteenth century—almost every society outside Europe had become or had been the colony of a western European state. Colonialism began as a series of crude ventures. Whether by force or by

treaty, sovereignty was seized, and exercised by governors responsible to foreign states. If indigenous rulers were retained, they mainly veiled the reality of power. As colonial states became more secure and elaborate, they intruded more pervasively into the daily life of subject populations; popular resentment seemed to foreshadow the gradual transfer of governmental machinery to indigenous nationalist leaders.

The actual outcomes were much less orderly. Dislodged or dislocated by the Second World War, and assailed by the United Nations rhetoric of national self-determination, many colonial states in South and South-east Asia passed without ceremony into the hands of nationalists; several in Africa negotiated independence before they had trained indigenous bureaucracies; others had to mount and endure sustained warfare to reach the same goal; and yet others—usually islands with small populations—chose to remain dependencies, with rights of individual entry into the former metropolitan country. A few fragments were retained by metropolitan powers, either as conveniently remote nuclear testing facilities or as significant entrepots. Despite this messy variety, most scholars believed that a logical narrative had come to an end: western colonialism, born in the sixteenth century and maturing until the twentieth, had reached its apotheosis in the sovereign states which succeeded them and took their places in the community of nations.

Yet colonialism continues to fascinate social scientists, both applied and theoretical. The successor-states were often bounded by arbitrary frontiers which exacerbated ethnic identities, and were vulnerable to the rivalries of the Cold War. Brave attempts to generate solidarity on the basis of the whole Third World, or even more modest efforts such as African unity, failed to reorient the ex-colonies' long-established links with the former metropolitan powers. Their inherited bureaucracies were better equipped to control than to mobilize the populace, and their formal economies were well designed to export unprocessed commodities. Their scanty education and training institutions could not immediately cope with the rising expectations of burgeoning populations. Independence was expected to liberate national energies in escaping from underdevelopment and backwardness, in pursuit of development and modernization. The United Nations Development Decade focused international attention on these goals, and academic centres of development studies graduated platoons of experts to assist in achieving them by finding technical solutions.

Few ex-colonies responded as planned, to strategies of agricultural intensification and economic diversification. Most of tropical Africa and some other parts of the world have performed so poorly that they have, in effect, retired from the global economy, their peoples committed to environmentally dubious practices in order to survive, their cities swelling and their recurrent budgets dependent upon aid flows. These catastrophes contrast sharply with the performance of the economic tigers of South-east and East Asia, whose success owes rather little to the advice of development experts. In either case, the imperatives of economic development legitimized authoritarian styles of government, which often adopted and elaborated the colonial structures of control in ways which hardly meet the old criteria of modernization.

These disconcerting tendencies add grist to the post-modernist mill and its critique of academic positivism. Stage theories of human progress have suffered especially badly at the hands of post-modern writers. Colonialism was not, after all, an aberration. Some see it as inherent in the western Enlightenment, quoting (for example) John Locke's opinion

that 'God gave the world to men in Common, but since He gave it them for their benefit and the greatest conveniencies of life they were capable to draw from it, it cannot be supposed He meant it should always remain common and uncultivated. He gave it to the use of the industrious and rational'. Edward Said's (1978) seminal *Orientalism,* and the Subaltern Studies pioneered and elaborated by expatriate South Asian scholars (Guha 1994), insist that colonialism was neither a finite era nor a particular set of governmental mechanisms. The desired achievement of post-colonialism therefore requires a great deal more than the application of technical solutions to discrete problems. Colonial apologetics and the triumphalist narratives of anti-colonial nationalism are portrayed as two sides of the same coin, alternative stage theories of social evolution which distort rather than illuminate past and present human experience. Only their deconstruction may exorcise colonialism's diffuse influences in the minds and practices of subalterns and superiors alike.

Just as colonialism has been applied beyond its earlier chronological limits, so it has burst its conventional boundaries in space. Ethnic identities which survived the homogenizing pressures of the modern nation-state have been unleashed by the end of the Cold War. When communities seek shelter from open competition, in solidarities which transcend market relations, ethnic identities are reasserted and historic charters invoked. Whether the immediate demands are political recognition and decentralized institutions, or land rights or other tangible benefits, the spectre of ethnic nationalism walks abroad, wearing the bloody robe of colonialism. Curiously, this extension of the term's application severs the ties with capitalism and imperialism, and brings it closer to an earlier usage, whereby the movement of any group of settlers into territory claimed or occupied by others could be described quite interchangeably as colonialism or colonization.

committees

The most notable committees are those that help govern nations—cabinet committees, legislative assemblies, party committees, and higher courts. But there are also boards of directors of corporations, labour union councils, state or provincial assemblies, and city councils, all of which are involved in governance. The term committee normally refers to

a face-to-face group of people who arrive at a decision through some means of polling member opinions. The types of committees mentioned have a firm institutional grounding and will have well-defined means of voting the issues that come before them. Their decisions have a semi-binding nature to them, perhaps subject to appeals or approvals elsewhere.

In contrast, there are many committees that are no more than advisory in nature, acting as a source of information for an administrator, a supervisor, or even a larger organization. For a larger organization, advisory committees offer a division of work, specialization, and economies of scale. For a single administrator or supervisor, advisory committees offer balanced judgement and a diversification of information sources beyond the ordinary chain-of-command. The growth of the seemingly infinite variety of committee organization and function has in many ways marked a decline in the traditional efficient chain-of-command method of conducting business. In a purely practical sense, technology has made it easier for committees to function effectively. Duplicating services and electronic transmission have made it more convenient to share information and communication and to arrange for meetings. Transportation advances have also facilitated the convening of committees.

The study of committees has progressed in two directions: in the study of single committees and in the study of committee systems. The study of single committees has concentrated on the justification of their use and voting strategies of members (see, e.g. Black 1958), or on the substantive decision making norms of very important groups. There has been increased attention given to committee systems, primarily in relation to legislatures. An eight-nation study of committee systems in national legislatures was completed in 1979 by Lees and Shaw which tried to determine the significance of the various committee systems in relation to other decision-making foci. The study confirmed, for example, as others suspected, that committee systems have the most central role in US legislatures, while political parties have a weaker role.

The organizers of committee systems are faced with several decisions: how to divide up the subject matter; how many committees; how many members on each committee; how many committee assignments per member; how much authority to delegate; and whether or not to have subcommittees within committees. In representative bodies, small committees sacrifice representativeness, yet they may be necessary under a heavy agenda (Francis 1989). The US Congress and state legislatures legislate through committees, and in Congress, the committees legislate through subcommittees. In other words, in the latter case, the subcommittees debate the subject before the committees deal with it. In Britain, India and Canada, the issues are debated on the floor before they are assigned to committee. In essence, committee systems are becoming complex forms of organization, and serve as an ample challenge in future theories of decision making.

commodity stabilization schemes

Schemes for the stabilization of primary commodity prices have always been an important item on the agenda of international policy discussions. This is because the prices of these commodities are volatile, and because exports of them are large sources of revenue for many countries, particularly those of the Third World. One of the most famous schemes was proposed by Keynes in 1942, as a companion to his International Clearing Union (which later became the IMF). Keynes's argument for commodity price stabilization led to political opposition from those opposed to market intervention and had to be shelved. More recently the same fate has befallen the Integral Program for Commodities put forward by UNCTAD (the United Nations Conference on Trade and Development). Those schemes which exist have developed in a piecemeal fashion. 'Only [schemes for] wheat, sugar, tea and coffee have lasted a number of years, and few appear to have achieved much before their demise' (MacBean and Snowden 1981).

Price stabilization is usually put forward as a means of stabilizing the incomes of producers and consumers. It could also be used as a means of raising the average incomes of producers, but would then need to be buttressed by quota schemes to restrict production.

Price stabilization will normally succeed in stabilizing revenues to producers in the face of shifts in demand for commodities of the kind which occur because of the world business cycle. The managers of the scheme need to operate some kind of buffer stock. When demand is high, the extra can be satisfied by sales from the buffer stock: producers' revenue is unaltered by the demand increase. The reverse is true when demand falls. Stabilization of prices will, it is true, allow fluctuations in producers' incomes to remain in the face of fluctuations in the quantity produced, as a result, say, of changes in harvests. However, without stabilization of prices, producers' incomes might be even more unstable, if good harvest produced very large falls in prices (and vice versa). Price stabilization will also isolate consumers of primary commodities from shocks to the purchasing power of their incomes in a wide variety of circumstances.

Economists differ in their assessment of the benefits to be obtained from such stabilization of prices. Newbery and Stiglitz (1981) have argued, in a powerful modern study, that the benefits to producers are small. Newbery and Stiglitz would clearly be

correct if producers could adjust their spending in line with fluctuations in their income. However, they ignore the great hardships which could arise when primary commodity producers (both individuals and nations) have to make unexpected cuts in expenditures. Such hardships will indeed arise when average incomes are not much above subsistence or when the revenue from sales of primary commodities is used to pay for development projects which are hard to stop and start at will. Newbery and Stiglitz also argue that the potential benefits to consumers would be small. But they largely ignore the inflationary difficulties for consumers which primary-commodity-price instability creates, and it was those which concerned Keynes. It must be admitted that contemporary proponents of primary commodity price stabilization schemes have been slow to produce good evidence about the size of those effects which Newbery and Stiglitz ignore.

There are fundamental difficulties in the way of setting up any stabilization scheme. It is necessary to choose not only the price level at which stabilization is to take place, but also the optimum size for the buffer stock. An obvious candidate for the price level is one which would balance supply with demand, averaging over the normal fluctuations in both supply and demand. But the amount of information required accurately to determine this price would be formidable for most commodities. As for the buffer stock, it should presumably be able to deal with the normal fluctuations in supply and demand. But in order to avoid running absurdly large stocks the objective of *complete* price stabilization would need to be abandoned, at least in extreme circumstances. Even so, the cost of operating the required buffer stock might be very large for many commodities. It is thus easy to see why those stabilization schemes which have been established have always been on the verge of breaking down.

communication networks

A network can be defined as a particular type of relation that links a set of people or objects, called the nodes of the network (Wasserman and Faust 1994). A communication network is a structure that is built on the basis of communication relationships between individuals, groups, organizations or societies. A networks perspective is a distinct research tradition within the social and behavioural sciences because it is based on the assumption that the attitudes and behaviours of the nodes (be they individuals or

collectives) are significantly enabled or constrained by the networks in which they are embedded.

Communication networks have been studied in various social systems and at differing levels of analysis. At the *intrapersonal level,* research has shown that individuals who have similar positions in the organization's network are more likely to have similar cognitions about the firm's products and processes (Krackhardt 1987; Pattison 1995; Walker 1985). In the area of *interpersonal relations,* researchers have shown that the degree of overlap between individuals' networks positively influences the development and stability of romantic relationships (Bott 1971; Parks and Adelman 1983). Research has also shown that an individual's interpersonal and community networks serve an important social support role in overcoming difficult life events (Albrecht and Adelman 1984; Wellman and Wortley 1990). In the context of small group behaviour, studies have shown that characteristics of the network's structure have a significant impact on the performance and satisfaction of group members involved in problem solving (Collins and Raven 1969; Shaw 1964). Considerable research has been conducted on communication and information flow in production, innovation, and informal social networks *within organizations.* For instance, Monge *et al.* (1983) showed that proximity, propensity to communicate, and commitment to the organization were important antecedents to the involvement of individuals in organizational networks. Researchers have noted that individuals' decisions to adopt new communication technologies are significantly predicted by the decisions of others in their communication network. Inversely, the adoption of new communication technologies significantly alters individuals' communication networks (Burkhardt and Brass 1990; Contractor and Eisenberg 1990). Likewise, there is a rapidly growing literature on the communication linkages among *inter-organizational* systems (Eisenberg *et al.* 1983; Mizruchi and Schwartz 1987). For instance, Galaskiewicz and Burt (1991) report that corporate decisions about making a philanthropic donation to specific non-profit organizations are positively influenced by the decisions of other donating officers in their inter-organizational communication network. At the broader *societal and cultural levels,* Rogers and Kincaid (1981) describe the uses of network analysis for the diffusion of ideas. Typical of this approach is their analysis of the communication patterns for the diffusion of family planning among sixty-nine women in a Korean village. These examples all employ 'people' as the nodes of the communication network, but this need not be the case. For example, Rice *et al.* (1988) used communication network analysis to demonstrate the influence of citation patterns among core journals in the field of communication.

Monge (1987) notes that two major objectives of network analysis are network articulation and metrics. In network articulation, individuals are assigned to various network role classifications such as clique member, liaison, and isolate. Liaisons do not belong to particular groups but have information linkages with people in two or more groups; they frequently figure importantly in linking groups together. As the name implies, isolates have few, if any, connections within the network. Research has shown that liaisons, isolates, and group members have different characteristics and function quite differently in communication networks (Monge and Eisenberg 1987). Network metrics refers to quantitative indices of various aspects of the network. The most frequently studied indices include density and centrality (Knoke and Kuklinski 1982).

The density of a network is the ratio of the number of observed links connecting nodes to the number of possible links between the nodes. A node is central in a network if it is connected to nodes that are not directly connected to each other.

Techniques for observing communication networks are many and varied (Monge and Contractor 1988). Often people are asked to recall their interactions with all other network members and to report the frequency, duration and importance of these contacts. In some studies, participants have been asked to keep diaries of their interactions during a given time period. In other research, participant-observers have logged the frequency of interactions among people in an organization. In one interesting series of studies, Milgram (1967) asked people to send a message to an unknown target by sending it through someone they knew personally. That process was repeated at each step until a person was eventually found who knew the target and delivered the message. An average of seven steps was required to reach the target. Bernard and Killworth (1980) collected data about the communication networks among ham radio operators by recording their public dialogue on the radio waves. Another example is the work of Rice (1995), who describes the use of computer-mediated communication systems to record the frequency and duration of communication linkages among individuals.

Analysis of communication network data, whether network articulation or metrics, is too unwieldy to be undertaken without a computer. While many network researchers write their own programs, there are a handful of network analysis and graphics packages available for use on microcomputers (for a review, see Wasserman and Faust 1994). The programs differ considerably in terms of the assumptions that they make about network data, objectives of the analysis, and computational algorithms.

Networks perspectives have emerged as an influential intellectual force in the social and behavioural sciences. While individual attributes (such as an individual's gender, age and education) are important sources of explanation for human behaviour, a number of social theorists (e.g. Burt 1982; 1992) have argued that they are incomplete and, in some cases, misleading. These theorists suggest that there are group and social phenomena that cannot be explained by the attributes of its constituents. In such cases, a networks perspective with its focus on the relationships between the constituents offers unique insights into collective phenomena.

communications

The social scientific study of human communication began during the late 1930s in the USA (Delia 1987). Schramm (1983) attributes the birth of this movement to four scholars: the political scientist, Harold Lasswell, the sociologist, Paul Lazarsfeld, and the social psychologists, Kurt Lewin and Carl Hovland. Though the parentage of any scholarly movement is bound to be ambiguous, many communication researchers would doubtless concur with Schramm's attribution, for these four pioneers not only authored much of the early influential communication research, but were also responsible for training a second generation of scholars who carried on their work.

The work of two of these founders, Lasswell and Lazarsfeld, centred almost exclusively on the impact of mass media on public information and attitudes, with some of Hovland's work at Yale University focusing on the same problem (see Hovland *et al.* 1949). Katz and Lazarsfeld (1955) note that the early traditions of communication research focused either on the media of public communication as instruments of clandestine manipulation or hope for them as agencies of social integration. Scholars in both traditions forwarded the 'hypodermic needle' model of media effects, positing that the media could 'inject' new information and attitudes into individual citizens in much the same way as a doctor could inject serum into a patient. As a result of the classic election studies conducted in the 1940s by Lazarsfeld and his colleagues (1948), a different, less communicatively hegemonous view of the mass media emerged, one positing that the media transmitted information to opinion leaders who, in turn, employed it to influence others in face-to-face settings—a process labelled 'the two-step flow hypothesis'. Although later research revealed that both the hypodermic needle model and the two-step flow hypothesis were oversimplified explanations of the impact of mass

media on individual attitudes and behaviours, these two notions exerted a strong influence on the thinking of mass communication researchers for several decades.

During roughly the same period, Lewin was conducting his famous studies at the University of Iowa concerning the effects of group decision making (Lewin 1958) and group leadership (Lewin 1939; Lippitt and White 1943) on the productivity and morale of group members, studies motivated at least partially by his repugnance for the fascist regimes emerging in Germany and Italy. With the advent of the Second World War, concern for ways of mounting effective public information campaigns against these Axis powers spawned the remarkably fruitful programme of research on communication and persuasion carried out by Hovland and his associates at Yale, a programme that produced an influential set of volumes which began appearing around the mid-1900s (Rosenberg *et al.* 1960; Sherif and Hovland 1961). Their work influenced communication researchers interested in the areas of small group communication and persuasion.

As the preceding chronicle suggests, most ground-breaking early work was problem-oriented and was conducted by scholars of varying disciplinary commitments. Communication did not emerge as an academic discipline until the late 1940s, one of the earliest signs of its emergence being the establishment, in 1947, of the Institute of Communications Research at the University of Illinois under the directorship of Wilbur Schramm. Influenced by the success at Illinois, research units were formed at other major midwestern universities including, most notably, at Michigan State University, University of Minnesota, and the University of Wisconsin. The growth of communication as a discipline accelerated rapidly in the 1960s and 1970s. Two Annenberg Schools of Communication were founded, the first at the University of Pennsylvania and the second at the University of Southern California. The newly christened departments were staffed by faculty whose degrees were from departments of journalism, speech, sociology, psychology, economics, and political science. But they all shared a common commitment to studying human communication processes.

As with most fledgling academic enterprises, consensus regarding conceptual delineation for the field has emerged slowly and equivocally. One approach to defining the field has focused on the various situational contexts in which communication may occur. This category system has produced researchers interested in mass communication, cross-cultural communication, health communication, technologically mediated communication, organizational communication, educational communication, small-group communication, family communication, marital communication, communication among children, interpersonal communication, non-verbal communication, and intrapersonal communication. A second approach has focused on various functions of communication, including socialization, conflict resolution, negotiation and bargaining, with persuasion and social influence receiving the lion's share of attention. Indeed, until the late 1960s, most of the theoretical, methodological, and empirical literature was devoted to the persuasion process. McGuire's (1969) ambitious summary of attitude and attitude-change work through the late 1960s has forty-two pages of references dealing with the topic.

Though persuasion research is certainly not a dead issue (Miller and Burgoon 1978), students of communication have diversified their interests considerably. Spurred by several important educational and scholarly occurrences, including the growth of interpersonal classes in the universities and the publication of Watzlawick *et al.*'s (1967)

Pragmatics of Human Communication, a number of researchers have turned to the study of symbolic transactions in more intimate, face-to-face settings. A lively interest has developed in examining the design of messages (O'Keefe and Lambert 1995) and message exchanges from a transactional, relational perspective (Folger and Poole 1982). Rather than using individual communicators as the unit of analysis, this approach uses the relationship: 'the focus of analysis is on the systemic properties that the participants have collectively, not individually' (Rogers and Farance 1975). Furthermore, greater emphasis has been placed on investigating communication relationships developmentally; that is, in looking at the evolution of relationships over time (Cappella 1984).

Three major paradigmatic alternatives have emerged to the earlier approaches. The *systems* perspective (Monge 1977; Watzlawick *et al.* 1967) stresses the structure and organization of all components of a system, rather than focusing on one or more underlying elements as would a reductionist approach. Contemporary treatments (Contractor 1994; Watt and Van Lear 1995) focus on studying how communication systems move from order into chaos (i.e. chaotic systems) or from chaos into order (i.e. self-organizing systems). The second major paradigm, the *interpretive* perspective (Putnam 1983) underscores the centrality of meaning in social interactions. It aims to unravel the subjective and consensual meanings that constitute social reality, by conducting naturalistic studies to document how symbols are invested with interpretations during interaction. A third paradigm, the *critical* perspective, is also concerned with the study of subjective social realities. However, unlike scholars from the interpretive paradigm, critical scholars assume a political stance in treating society as circumscribed by power relations (including materialistic forces such as capital) and conflict. Their efforts, which have been focused primarily in the arena of popular culture (Grossberg 1992), gender issues (Treichler and Kramarae 1988), and sexuality (Vance 1987), often incorporate interventionist strategies for changing both discursive and material conditions.

As the study of communication moves into the twenty-first century, these paradigmatic debates, buttressed, one hopes, by more durable research foundations, will doubtless continue. In addition, the burgeoning communication technology is likely to generate more intensive efforts to identify the interfaces between mediated and face-to-face communication systems (McGrath and Hollingshead 1994). The precise nature of these influences constitutes an important priority for future communication research.

communism

Communism connotes any societal arrangement based on communal ownership, production, consumption, self-government, perhaps even communal sexual mating. The term refers both to such societies and practices and to any theory advocating them. Examples of the former can be found in religious orders throughout history and in radical communities, from the sixteenth-century Anabaptists to the contemporary 'counterculture'; and the most famous example of advocacy of communism may well be the regime proposed for the guardian caste in Plato's *Republic.*

In the middle of the nineteenth century, the most radical schools of the growing socialist movement, including that of Marx and Engels, called themselves communists in order to dissociate themselves from other, allegedly less consistent, socialist groups. Hence when reference is made to that period, communism often is synonymous with the system of ideas developed by Engels and Marx, even though they often used the terms communism and socialism interchangeably. Communism in this sense connotes the sum-total of Marxist doctrines; hence it is the Marxist critique of capitalism and liberal theory and the project for the proletarian revolution, though at times it connotes specifically the ultimate goal of that revolution—the society visualized as emerging out of it, which is dimly foreseen as a society without property, without classes or a division of labour, without institutions of coercion and domination. The precise features of this society are not delineated in the writings of Marx and Engels, and among Marxists there are controversies about the degree of residual alienation and oppression (if any) that one ought to expect in the communist society of the future. Some of the hints Marx and Engels themselves gave come from their notion of a primitive communism allegedly prevailing among the savage early ancestors of the human race.

Among the earliest followers of Engels and Marx, the term fell into disuse; most Marxists around the turn of the century called themselves Social-Democrats. The term was revived after the Russian Revolution of 1917 by V.I.Lenin, who renamed his faction of the Russian Marxist movement the Communist Party and compelled all those parties who wished to join the newly-created Third (or Communist) International to adopt the same designation, so as to dissociate themselves from the Social-Democratic parties. As a consequence, communism since then connotes that interpretation of Marxism which considers the ideas and actions of Lenin and his Bolshevik faction to be the only correct interpretation of Marxism, and the sum-total of parties that subscribe to this interpretation.

Leninism is characterized by the insistence that meaningful social change can come only through revolution, while reforms threaten to corrupt the oppressed. Further, it implies the application of Marxism to countries where capitalism is underdeveloped,

hence the development of flexible political strategies, including the mobilization of peasants and ethnic minorities for revolution. Foremost, it insists on the need for a 'vanguard party' of revolutionaries-by-profession to whom correct knowledge of the laws of history and politics ('consciousness') is attributed. Within the party and its numerous auxiliary organizations designed to mobilize the working class and its presumed allies, the vanguard is expected to ensure the prevalence of enlightened consciousness over blind passion by a combination of mass initiative and bureaucratic control that Lenin called 'democratic centralism'. Finally, Leninism implies the accumulated experience of the Russian Communist Party in governing their country. Communism thus connotes the theory and practice of rule by communist parties.

Although the leaders of ruling communist parties have generally refrained from claiming that the systems they were ruling were communist, it has become customary in the western world to refer to them as communist systems. Communism thus refers to any society or group of societies governed by communist parties.

The mature form of communist rule was developed in the USSR under the rule of J.V.Stalin. Hence communism since the 1930s has become synonymous with Stalinism or Neo-Stalinism. This is a system in which the communist party proclaims itself the enlightened leadership and claims authority to speak for the entire nation. It enforces this claim through control over all organizations and associations, all forms of communication, education, and entertainment, individual appointments and careers. The chief aim of these systems is rapid economic growth through crash programmes of industrialization, carried out through a centralized command economy. Communism in its Stalinist form thus is a species of entrepreneurship.

Contemporary communist societies thus bear no resemblance to the vision of communism sketched by Marx and Engels or even to that provided by Lenin in his unfinished work, *The State and Revolution.* Yet the memory of that vision lingers and has repeatedly led to attempts within communist parties to define alternatives to Leninist and Stalinist theories and practices. Contemporary communism therefore is not one single orthodoxy, but an ever growing cluster of orthodoxies and heresies, all of them backing up their arguments by reference to Engels and Marx, yet fiercely contending with each other.

Twentieth-century communism began as a dream to create an ideal society and an empowered human being. It turned into a clumsy crash programme of anti-capitalist capital accumulation, of westernization despite the west. That project has now collapsed in the European part of the communist world; the command economies have yielded to various modes of privatization and the market, doctrinal orthodoxy and the leadership claims of communist parties have been replaced by a multiplicity of parties and ideologies. Ethnic hatreds long tabooed and suppressed have erupted into the open, tearing empires and states apart in bloody conflict. The agony of this revolutionary process has led many citizens of the formerly communist countries to look back to the rule of the communist parties with nostalgia, while for others everything connected with communism has been thoroughly and irreversibly discredited. General opinion in the 'west' considers communism to be dead; but that may be premature.

community

The term community relates to a wide range of phenomena and has been used as an omnibus word loaded with diverse associations. Hillery (1955) unearthed no fewer than ninety-four definitions of community and its definition has continued to be a thriving intellectual pastime of sociologists.

A preliminary confusion arises between community as a type of *collectivity* or social unit, and community as a type of *social relationship* or sentiment. The root of the problem could be traced to Tönnies's *Gemeinschaft,* which uses the term to describe both a collectivity and a social relationship. Subsequently, most scholars have used community to connote a form of collectivity (with or without *Gemeinschaft* ties), but some, such as Nisbet (1953), have kept the community-as-sentiment approach alive in their emphasis on the quest for community and their concern with the loss of community in modern life. These approaches are clearly mixed with some nostalgia for a glorious past in which people were thought to be more secure, less alienated and less atomized. But, as Schmalenbach (1960) pointed out, Tönnies's *Gemeinschaft* implied a spontaneous, taken-for-granted relationship. Fellowship ties which are consciously sought and are more emotionally laden better fit what he called communion *(bund)* ties, such as those found in religious sects or ideological groups. Communion ties are often created by precisely those people who are dissatisfied with the routinization (hence loss of meaning and involvement) of the extant community ties.

Community, in the sense of type of collectivity, usually refers to a group sharing a defined physical space or geographical area such as a neighbourhood, city, village or hamlet; a community can also be a group sharing common traits, a sense of belonging and/or maintaining social ties and interactions which shape it into a distinctive social entity, such as an ethnic, religious, academic or professional community. The differences are between what may be called territorial and non-territorial approaches. For some scholars (Hawley 1950; Park 1929) the most important bases of commonality is common territory. While they do not dismiss the essential element of common ties, these ties are not sufficient in themselves to constitute a community. The non-territorial approach

stresses the common ties at the expense of territory. Community still denotes a *social entity* with common ties and not the ties themselves, but territory is not a necessary ingredient of commonality. Common ties and a sense of belonging may derive from beliefs in a common past or a common fate, common values, interests, kinship relations and so on, none of which presuppose living together, as illustrated by ethnic or religious communities whose members might be geographically dispersed. We still do not know, however, what is distinctive about community ties compared to ties of other collectivities. Since locality is not the distinctive feature in this approach, one looks for distinctiveness in the type of ties. This may in turn re-create the confusion between community as a form of collectivity or community as a form of human bond. The non-territorial approach has gained force as a result of modern advances in communication which have reduced the importance or territorial proximity as a bases for human association, increasingly creating what Webber (1964) called 'community without propinquity'. A related non-territorial approach is found among social network theorists, some of whom also object to treating communities as social entities in their own right, regarding this a legacy of Durkheimian corporationist tendencies as opposed to Simmel's interactionist approach (Boissevain 1968).

Hillery (1968) and Gottschalk (1975) have made the most systematic attempt to differentiate between formal organization and community (or rather communal organization). The formal organization's primary orientation towards a specific, defining goal is contrasted with the communal organization's primarily diffuse goal orientation. Azarya (1984) has added that formal organizations are basically instruments established to attain external goals whereas communities' goals are mostly inner-oriented: they strive to maintain a set of desired relationships among fellow members and a state of affairs within the collectivity. In their goal-related activities, members of formal organizations relate to one another as specific role-bearers, while relations among members of communal organizations are more diffuse, encompassing a larger aspect of one another's life. Corporations, schools, churches, armies, political movements and professional associations are all formal organizations, while families, ethnic groups and neighbourhoods are communal organizations. Communal and formal organizations can, of course, include sub-units of the opposite kind, as for example informal community-like friendship groups among workers of an industrial plant, or, by contrast, voluntary associations created within a neighbourhood or an ethnic community.

Delineating the boundaries of communities is one of the greatest difficulties hampering their proper identification. The lack of clear boundaries is indeed one of the major properties of communities as compared to formal organizations (Hillery 1968). In non-territorial communities, clear boundaries and sharp differentiation between members and non-members are signs of association formation within the community, which brings it closer to the formal organization pole. In territorial communities, if no size limitations are set on 'the people living together' which the community is said to represent, the concept may be stretched to include an entire nation or even the world at large (Warren 1973). Some scholars (Hawley 1950) prefer to limit community to a size which enables the inhabitants to have a diffuse familiarity with the everyday life of the area. While one knows about special events that occur outside the community, familiarity with one's own community includes ordinary events which would not draw attention elsewhere. This

would exclude global, national and metropolitan areas from being called communities.

However a measure of maximal size may be specified, what would be the minimal size of a territorial community? The smaller the community, the greater its members' familiarity with routine life, but would that make a single house (or an apartment building) a community? According to Warren, some basic functions have to be performed in each community, including the provision of basic economic needs, socialization, social control, social participation and mutual support (Warren 1973). The community might depend on external organizations in performing these functions, and community members do not have to prefer locally offered services to external ones, but some activity has to take place in the community in each of these spheres. This would exclude an apartment building or a modern nuclear family from being a community in its own right, though not necessarily the pre-modern extended family household. A related feature of community stressed in the literature is its being a microcosm of society. The community, unlike other collectivities, is a social system in itself, including such subsystems as government, economy, education, religion, and family found in a larger society. A certain size has to be attained for these institutional spheres to manifest themselves. It is also possible that the community loses some of its multifaceted characteristics in more developed societies, becoming less differentiated as societies become more so (Elias 1974).

The conceptual disarray of social science regarding community has not prevented an abundance of community studies, some of which are among the best known pieces of social science literature. The various urban studies of the Chicago school in the 1920s and 1930s, Warren and Lunt's (1941) *Yankee City,* Redfield's (1949) *Tepotzlan: A Mexican Village,* Whyte's (1961) *Street Corner Society,* Gans's (1962) *Urban Villagers* and (1967) *Levittowners* are just a few examples of a much longer list. Scholarly interest in community has included units of greatly different size, autonomy, demographic composition, technological, economic or cultural traits. Community characteristics have been used to explain other phenomena—inequality, deviance, transformative capacity. Special attention has focused on the extent to which urban-rural differences can explain variations in community structure and interactions (Wirth 1938). Doubts have been raised about the narrative style and idiosyncratic methodology of most community studies which make them irreproducible and hard to compare. Ruth Glass called them 'the poor sociologist's substitute for the novel' (Bell and Newby 1971), but perhaps this concrete quality and the 'story' that they carried has been their greatest advantage.

community development

In the context of public policy, the phrase community development has most often been used to describe projects initiated by, or with the active participation of, the inhabitants of a locality, which are intended to benefit them collectively. The projects may concern education, social welfare, health, infrastructure such as roads, wells or irrigation, farming, manufacture or commerce. While much of the benefit may accrue to individual families, the projects are intended to enhance the community as a whole, in self-confidence and political skills, for instance, even if not more tangibly.

This conception of community development was widely adopted by British, French and Belgian colonial administrations in Africa and Asia, especially after the Second World War, as a social and political as much as economic strategy for rural areas. In British Africa; for example, departments of community development were created with community development officers trained according to increasingly self-conscious principles of professional community development practice (du Sautoy 1968; Batten 1962). The stimulation of local leadership, the growth of capacity to initiate projects and organize self-help, and the learning of skills were characteristically considered more important than the achievements of any particular project. The ideal community development officer was therefore a facilitator, adviser and sensitive guide, who sought to encourage a collective capacity for initiative and organization that would then continue

independently.

In practice, the community development officer's role was more ambivalent than this ideal allowed. As a government employee, he was bound to favour local initiatives which corresponded with national policy and discourage others. His intervention was often crucial in drawing local factions into co-operation and in securing resources. Hence community development remained essentially an aspect of government policy, although a variety of mutual aid and village development associations evolved independently of government—as for instance in Eastern Nigeria.

After independence, community development was seen as a means of mobilizing rural people for such endeavours as mass literacy or education, as for instance in the movement for self-reliance in Tanzania, or the Harambee movement in Kenya. But the inherent ambiguity remains of a strategy intended both to encourage self-help and initiative while implementing national government's goals.

In the 1960s, the term community development came to be applied to projects in predominantly urban neighbourhoods of America and later Britain, where poverty and social pathologies were believed to concentrate. Like their colonial predecessors, these projects were intended both to provide practical benefits, such as improved social services, more relevant vocational training, legal aid, low-cost housing and more jobs, and, in doing so, to increase the community's sense of its collective competence. In the United States, this approach became national policy under Title II of the Economic Opportunity Act of 1964, following earlier experiments by the Ford Foundation and the President's Committee on Juvenile Delinquency (Marris and Rein 1980) and was continued in many subsequent policies, such as the Model Cities Program and Community Development Block Grants from the federal to local governments. Besides community action agencies, largely concerned with social welfare and educational programmes, community development corporations were funded to promote housing and commercial enterprises, especially in neighbourhoods of high unemployment. The Watts Labor Community Action Coalition, for instance, has, at various times, developed produce markets, a bus service, a large shopping centre, and housing in a black district of Los Angeles (Hampden-Turner 1974). Apart from housing, development corporations have experienced great difficulties in sustaining viable commercial enterprises in their communities. In most instances, the attempt to fulfil social purposes, such as employment opportunities for local residents, in market settings which more experienced commercial enterprises have already judged unprofitable, proves too difficult even with the help of subsidies. Over time, therefore, the corporations tend either to withdraw from commercial endeavours or to defer many of their original social reasons for starting them.

The British Community Development Project, modelled on American community action agencies, was initiated in 1969 by the Home Office with a similar hope of stimulating self-help and innovative solutions in neighbourhoods of concentrated social problems, choosing for the experiment twelve mostly urban neighbourhoods in Britain (Marris 1982). Over time, as concern shifted from social pathology—which was neither as apparent nor as concentrated as had been assumed—to unemployment, the project had to confront the difficulty of applying very localized resources to remedy the effects of large-scale changes of economic structure.

Both the British and American projects were regarded as experimental by the

governments which initiated them. Community development, in this context, was intended to discover inexpensive solutions to problems of poverty and unemployment, through self-help and innovative, more relevant and efficient use of resources already allocated. It has therefore never received funding on a scale commensurate with the problems it addressed. Its most lasting achievement, especially in the United States, probably lies in the growing sophistication and organizational capacity of neighbourhood groups in dealing with economic and physical changes which affect them.

competition

The simplest meaning of the term is rivalry between alternative buyers and sellers, each seeking to pursue their own ends. It is central to economics because it provides the mechanism through which the actions of agents can be co-ordinated. It is the basis for Adam Smith's claim that every individual 'is led by an invisible hand to promote an end which was no part of his intention' (Smith 1979 [1776]: 456). It requires both a plurality of potential buyers and sellers and a competitive attitude. Thus its opposite may be either monopoly (the usage in most modern economics) or custom and co-operation (as was the case for J.S. Mill).

When Adam Smith and the classical economists used the term competition, they referred to the process whereby prices were forced down to costs of production, and wages and profits to their 'ordinary' levels. The requirement for this was what Smith termed 'perfect liberty' in which there are no barriers to mobility and 'every man, as long as he does not violate the laws of justice, is left perfectly free to pursue his own interests in his own way, and to bring both his industry and his capital into competition with those of any other man' (Smith 1979 [1776]:687). This is what has since been termed the long period aspect of competition, the process whereby capital and labour are moved from one activity to another taking considerable time. In contrast, the short period aspect of competition concerns the way markets operate. For the classical economists, the short period aspect of competition was summarized by the law of one price: the proposition

that there cannot be two prices in the same market. It embodies a static notion of competition, for the process whereby price differences are eliminated is ignored.

Between the 1870s and the 1930s a number of economists (notably W.S.Jevons, L.Walras, F.Y. Edgeworth, V.Pareto, A.Marshall and K.Wicksell, J.Robinson and E.H.Chamberlin) developed the concept of perfect competition. Like the law of one price, and in contrast to what the classical economists understood by competition, perfect competition is a static concept. It is not a process but a type of market in which each agent is so small as to be unable to influence the price at which goods are bought and sold. Agents are price-takers. It is contrasted with imperfect competition, a state in which individual agents are sufficiently large to be able to have some control over the price of what they are buying or selling. Imperfect competition covers a variety of market structures ranging from monopoly (one seller) and monopsony (one buyer) to oligopoly (a small number of sellers) and bilateral monopoly (one buyer and one seller).

Perfect competition is a situation where most of the phenomena commonly associated with competition (brands and product differentiation, advertising, price wars— phenomena that were extensively discussed in the late nineteenth-century US literature) are absent, yet it has provided the dominant theory of competition in economic theory since the 1940s. Economists have explored, with great rigour, the conditions under which perfect competition will occur. Perfect competition has been shown to be efficient in the sense that in a perfectly competitive equilibrium it is impossible to make any individual better off without simultaneously making someone else worse off (Pareto efficiency). Perfect competition was, at least until the 1980s, the almost universally used assumption about market structure in diverse areas of economics such as international trade, inflation and unemployment.

The main reason why economists rely so heavily on models of perfect competition is that imperfect competition, in particular oligopoly, is much more difficult to analyse, one of the main problems being that in order to work out what is the best action to take, agents (usually firms) have to take into account how their competitors are likely to respond. Nowadays the most widely accepted solution to this problem is to use game theory. Using game theory economists have managed to construct theoretical models of aspects of competition such as entry deterrence, strategic investment, product variety and R&D expenditure.

While the focus of most economic theory has been on perfect competition, dynamic aspects of competition such as concerned Smith and the classical economists have not been neglected. The Austrian School, based on the work of C.Menger, sees competition as a dynamic process of discovery, dominated by the figure of the entrepreneur. It is entrepreneurs who see the possibilities for making profits by producing new goods, or by producing existing goods in new ways. The competitive process involves the continual creation and subsequent elimination of opportunities for profit. The contrast between orthodox and Austrian conceptions of competition is shown by the debate, in the 1920s and 1930s, over whether rational (i.e. efficient) economic calculation was possible under socialism. Market socialists such as O.Lange focused on the static concept of perfect competition, arguing that it was possible to design a set of rules for a socialist economy (in which there was no private ownership of capital) that would produce the same allocation of resources as would occur in a competitive, capitalist economy. Against

them, Austrians such as L.von Mises and F.A.von Hayek argued that competition in the sense of rivalry was necessary if new products and new technologies were to be discovered: that those aspects of competition that K.Marx saw as wasteful (e.g. the building of two factories, one of which was subsequently eliminated by competition) were a vital feature of capitalism that could not be emulated under socialism.

Perhaps the best-known economist working in the Austrian tradition was J.A.Schumpeter. His vision was of competition as a process of 'creative destruction'. Entrepreneurs discover new technologies, earning large profits as a result. Over time their discoveries are imitated by others, with the result that competition forces profits down. This theory fits into a longer tradition of evolutionary theories of competition, whose history goes back to the social Darwinism of the late nineteenth century in which competition was seen as eliminating the unfit. Among the most prominent modern exponents of evolutionary theories of competition are R.R.Nelson and S.G.Winter, who combined the Austrian idea that entrepreneurs explore alternative ways of responding to novel situations with the Darwinian idea that those who make good choices survive, with competition eliminating those who make bad ones.

The Austrian emphasis on innovation also results in a different attitude towards the role of numbers in competition. The standard view is that the smaller the number of firms, the less is the degree of competition. Attempts have therefore been made to measure competition by measuring variables such as concentration ratios—the share of output produced by, say, the largest five firms. Austrians, however, emphasize potential competition, which may be unrelated to the number of firms in the industry. A similar line has been pursued by W.J.Baumol who has developed the notion of a 'contestable' market. A perfectly contestable market is one in which entry and exit are absolutely costless, the result being that potential competition will keep prices low even if there are few firms in the industry.

computer simulation

Computer simulation is a methodology for building, testing and using computer programs which imitate (Latin *simulare,* to imitate) some aspect of social system behaviour. Since its inception in the 1960s, computer simulation has continued to be a specialized and useful tool for addressing a variety of social science topics, including settlement patterns in archaeology, small population dynamics in anthropology, voting behaviours in political science, family and kinship processes in demography, and outcomes assessment in social policy analysis.

A computer simulation model is embodied in a computer program which uses numbers or symbols to represent observed variables in a social system, along with programming statements that attempt to mimic the behaviour of the system. In order to start the simulation, initial values are set for the variables and for the parameters which determine the behaviour of the system. Then, the simulation program executes and produces outputs showing how the values of variables change over time. By re-specifying initial values and parameters the modeller can experiment with alternative hypotheses in ways that might be impossible, impractical or unethical in a real social system.

Experiments with computer simulation models yield insight into the operation of complex social systems. While some simulation models might also be useful for making limited predictions of the future, most social scientists are pessimistic about the reliability of such predictions. Thus, the goal of simulation experiments is usually to obtain a better understanding of complex social processes and our theories and hypotheses rather than to make predictions of the future.

Computer simulation models can be conveniently classified as *macro-simulation* models or *micro-simulation* models. A macro-simulation model operates much like an accounting system. It presents the state of a social system in a numerical accounting statement, such as counts of numbers of people by age, gender and social characteristics in a population. The macro-simulation program then adds and subtracts from these numbers in ways that imitate social processes operating over time, such as by adding to counts of infants and subtracting from counts of people at all ages to simulate birth and death processes, respectively. Many macro-simulation models can be expressed as mathematical equations, so that the computer simulation model is simply a tool for deriving results from the mathematical model.

M*icro-simulation* models are usually more complex and detailed than macro-simulation models. Microsimulation models operate by keeping track of each individual entity (e.g. person, institution, family) and its attributes (e.g. age, gender, size, social characteristics) in a small artificial population maintained in computer memory. Using a simulation clock to imitate the passage of time, the micro-simulation program schedules events (e.g. birth, death, marriage, change in status) which happen to these simulated individuals at specified times. At various times during the simulation a statistical output or perhaps a 'census' listing of the simulated individuals and their characteristics is produced for later analysis. Micro-simulation models are usually difficult or impossible to express with traditional mathematical methods, so that micro-simulation methods open new vistas in social science research.

Micro-simulation models are usually stochastic models, meaning that some degree of controlled randomness is included in the models. Random variables are created from pseudo-random numbers generated on the computer and these random variables can be created to conform to any of a wide variety of probability distributions. In this way micro-simulation models typically represent patterns of variation, randomness, and uncertainty in social systems as an integral part of the simulation model. The results produced by the simulations therefore display patterns of variability between individuals, and over time, similar to real-world data. Because of their random component, micro-simulation models are part of the larger class of statistical and computational techniques known as Monte Carlo methods.

A complete micro-simulation experiment consists of numerous replications (computer runs) which differ from each other due to the random component. The principles of experimental design and analysis, including analysis of variance, apply to designing and analysing micro-simulation experiments just as they do to empirical research. But unlike empirical research, micro-simulation research allows the modeller to control the patterns of randomness so that it is also a subject for investigation and experiment. Moreover, because the random component of a simulation is controlled by the modeller, special variance reduction techniques can be employed to increase the statistical efficiency of the results (Rubinstein 1981).

A critical, but often slighted, task in computer simulation work is testing the model. Among the tests which should be conducted and reported on any computer simulation model are verification, validation and tuning. Verification examines a simulation program for logical errors and programming mistakes; validation compares simulation outputs to real data as an empirical check on the model; tuning refines the model to increase its validity and reduce its sensitivity to extraneous factors. It can be particularly difficult to test a micro-simulation model thoroughly because some errors surface only when rare events or combinations of events happen to occur. Thus, the more complex and the more probabilistic the micro-simulation model is, the harder it is to test. This is a good reason for keeping simulation models as simple as possible while at the same time engaging in thorough testing under a wide variety of initial inputs and parameter values.

As with any scientific model, the simulation modeller faces difficult choices between creating a more complex and comprehensive model that is more difficult to understand and test, versus devising a simpler and more limited model that is more thoroughly tractable and testable (for discussions see the essays by Nathan Keyfitz and Kenneth

Wachter in Bongaarts, Burch, and Wachter, 1986). As one example of this tension, in the United States, the National Research Council has given strong endorsement to the use of micro-simulation modelling in policy analysis while at the same time strongly emphasizing the need for much better validation and documentation of existing and future simulation models (Citro and Hanushek 1991).

The practice of computer simulation is closely tied to the technology of computing. The early micro-simulation experiments of Orcutt *et al.* (1961) consumed vast amounts of computer time on a large computer that was many times slower and had many times less memory than today's inexpensive desktop or portable microcomputers. But even with modern computers, micro-simulation models typically require relatively large amounts of computing time and memory, partly because of the need for many replications in a simulation experiment. However, the task of efficient simulation programming is greatly enhanced by special programming languages (e.g. Schriber 1991) which provide efficient memory management, mechanisms for event timing, and fast generation of pseudorandom numbers. Many texts (e.g. Mitrani 1982; Payne 1982) introduce the concepts, issues and programming languages relevant to computer simulation.

Comte, Auguste (1798–1857)

Auguste Comte, philosopher of science and social visionary, is perhaps best known for giving a name to a subject he outlined rather than practised: sociology. As the Comtist motto 'Order and Progress' suggests, the keynote of his thought is his search, in chaotic times, for principles of cultural and political order that were consistent with the forward

march of society. Born at Montpellier in southern France of a conservative, middle-class family, Comte received a good scientific education at the Ecole Polytechnique in Paris, a centre of advanced liberal thought. From 1817 to 1824 he was closely associated with the radical prophet of a new industrial order, Henri de Saint-Simon, to whom he owed a considerable (and largely disavowed) intellectual debt. At the same time, despite the loss of his Catholic faith, he was drawn to some of the ideas of the conservative thinker, Joseph de Maistre, and eventually based much of the 'religion of humanity' on medieval, Catholic models.

Comte's writings fall into two main phases, which express different aspects of a single, unified vision of knowledge and society, rather than a change in fundamental emphasis. Of the first, the major work is the six-volume *Cours de philosophic positive* (1830–42). (*The Positive Philosophy of Auguste Comte,* 1896), which sets forth a developmental epistemology of science. In his later writings, especially the *Discours sur l'esprit positif,* (1844) *(Discourse on the Positive Spirit),* the *Système de politique positive* (1848–54) (*System of Positive Polity,* 1875–77), and the *Catechism of Positive Religion* (1858), Comte gives the blueprint of a new social order, including the 'religion of humanity' which was to provide its ethical underpinning. For Comte, 'positivism' was not merely the doctrine that the methods of the natural sciences provide the only route to a knowledge of human nature and society (as it has latterly come to mean), but also a source of value for social reorganization. 'Sociology' is, in fact, the specific knowledge requisite to this task.

In the *Cours* Comte sets forth the famous 'Law of the three stages'. In its origins, human thought is 'theological', making use of an idiom of spiritual forces; later, in a phase which culminates in the Enlightenment, it moves to a 'metaphysical' stage, which is conjectural and largely negative; finally, when it is able to grasp real causal relations between phenomena, it achieves the scientific or 'positive' stage. To these stages there also correspond characteristic social and political institutions. Individual sciences develop in the same manner, emerging at the positive stage in the order of their complexity: mathematics, astronomy, physics, chemistry, biology and, finally, sociology. Comte's view of sociology is highly programmatic: he argues for an analytic distinction between social 'statics' and 'dynamics', and for society to be analysed as a system of interdependent parts, based upon a consensus.

Despite his religious eccentricities, Comte exercised an immediate influence on his comtemporaries. J.S. Mill introduced his work to the English-speaking world, where the positive philosophy appealed as a check to the extremes of liberal individualism, and even Spencer adopted the name 'sociology'. Though he is little read today, the functionalist and natural scientific paradigms which Comte advocated have remained in sociology's mainstream.

conditioning, classical and operant

The Russian physiologist, Ivan Pavlov, was not the first scientist to investigate how animals learn, but he was certainly one of the first to undertake a systematic series of experiments intended to provide precise quantitative information on the subject, and it is to his work that we owe the term conditioning to describe one form of that learning. In the course of his work on the digestive system of dogs, Pavlov had found that salivary secretion was elicited not only by placing food in the dog's mouth but also by the sight or smell of food, and that eventually a dog might start to salivate at the sight or sound of the attendant who usually provided the food. These 'psychic secretions', although initially interfering with the planned study of the digestive system, provided the basis for the study of conditional reflexes for which Pavlov is now far more famous.

Pavlov's experimental arrangement was simple. A hungry dog is restrained on a stand; every few minutes, the dog receives some meat powder, the delivery of which is signalled by an arbitrary stimulus, such as the ticking of a metronome or the flashing of a light. The food itself elicits copious salivation, which is measured by diverting the end of the salivary duct through a fistula in the dog's cheek. After a number of trials on which the delivery of food is always preceded by the ticking of the metronome, the dog does not wait for the food, but starts to salivate as soon as the metronome is sounded. Food is referred to as an unconditional stimulus because it unconditionally elicits salivation; the metronome is a conditional stimulus which comes to elicit salivation conditional on its relationship to the food. By similar reasoning, salivation to food is an unconditional response, but when the dog starts salivating to the metronome, this is a conditional response, strengthened or reinforced by the delivery of food whenever the metronome sounds, and weakened or extinguished whenever the metronome occurs without being followed by food. In translation from the original Russian, 'conditional' and 'unconditional' became 'conditioned' and 'unconditioned' and the verb 'to condition' was rapidly introduced to describe the procedure which brought about this change in the dog's behaviour.

At about the same time as Pavlov was starting his work on what is now called classical conditioning, a young American research student, Edward Thorndike, was undertaking an equally systematic series of experiments which are now regarded as providing the first analysis of operant conditioning. Thorndike was more catholic in his choice of animal to

study than was Pavlov, using cats, chickens and monkeys impartially. The impetus for his work was also different. While Pavlov was a physiologist who saw himself as studying the brain and how it controlled not only inborn but also acquired reflexes, Thorndike was concerned to study how animals learned in an objective and scientific manner in order to dispel the myths that he thought had arisen about the amazing feats of intelligence of which animals were capable, myths that owed much to a post-Darwinian desire to prove the mental continuity of humans and other animals.

In a typical experiment, Thorndike would place a cat in a puzzle box from which the animal could escape, and so get access to a dish of food, only by performing some arbitrary response such as pressing a catch or pulling on a piece of string. Thorndike recorded the time it took the animal to perform the required response on successive trials, and observing a gradual decline in this time, interpreted the learning in terms of his celebrated 'law of effect': the reward of escaping from confinement and obtaining food strengthened the one response that was successful in achieving this, while all other responses, being followed by no such desirable effects, were weakened.

The term operant conditioning was introduced by the American psychologist, B.F.Skinner, who refined Thorndike's procedure by the simple device of delivering food to the animal (via, for example, an automatic pellet dispenser) while it remained inside the box. In this apparatus, a rat could be trained to perform hundreds of responses, usually pressing a small bar protruding from one wall, in order to obtain occasional pellets of food. The response of pressing the bar was termed an operant because it operated on the animal's environment, and the procedure was therefore operant conditioning, which was reinforced by the occasional pellet of food, and extinguished if pressing the bar was no longer followed by food.

Although Skinner, unlike Thorndike, took over much of Pavlov's terminology, he interpreted the learning he observed in a way much more closely related to Thorndike's analysis. For Skinner, as for Thorndike, the central feature of learning and adaptation is that an animal's behaviour should be modified by its consequences. The rat presses the bar because this response produces a particular outcome—the delivery of food; when it no longer does so, the rat stops pressing the bar, just as it will also stop if pressing the bar produces some other, less desirable outcome such as the delivery of a brief shock. The schedules according to which the experimenter arranges these outcomes have orderly and appropriate effects on the animal's behaviour.

The law of effect, which summarizes these observations, is entirely in accord with common sense: parents hope and believe that rewarding children for good behaviour or punishing them for bad will also have appropriate effects, and when they are mistaken or disappointed we are more inclined to look for other sources of reward or to question the efficacy of their punishment than to question the underlying logic of the argument. Operant conditioning, therefore, although no doubt only one, rather simple form of learning or way of modifying behaviour, is surely an important and pervasive one. It is not so immediately obvious that the process of classical conditioning identified by Pavlov is of such importance. Why does the dog start salivating at the sound of the metronome? The experimenter delivers the food regardless of the dog's behaviour (this, of course, is the precise distinction between classical and operant conditioning, for in Skinner's experiments the rat gets food only *if* it presses the bar). It has been argued that salivation

does actually achieve something—for example, it makes dry food more palatable and this is why the dog learns to salivate in anticipation of food. The explanation attempts to interpret classical conditioning in operant terms, for it seeks to identify a desirable consequence of salivation responsible for reinforcing the response. But the explanation is probably false. Another popular example of classical conditioning is that of blinking by a rabbit to a flash of light which signals the delivery of a puff of air to the rabbit's eye. Since this is a classical experiment, the puff of air is delivered on every trial regardless of the rabbit's behaviour. Just as in the case of the dog's salivary response, however, it seems reasonable to argue that the rabbit's eye blink serves to protect the eye from the puff of air and is therefore reinforced by this desirable consequence. The argument implies that if the experimenter arranged that on any trial on which the rabbit blinked in anticipation of the puff of air, the experimenter cancelled its delivery altogether, the rabbit would learn to blink even more readily. Here, after all, blinking has an even more beneficial consequence than usual: it completely cancels an aversive consequence. But in fact such a procedure significantly interferes with the conditioning of the rabbit's eye blink.

A more plausible interpretation, then, is that classical conditioning simply reflects an animal's anticipation of a particular consequence, not necessarily an attempt to obtain or avoid that consequence—this latter being the provenance of operant conditioning. Classical conditioning probably has its most important application in the area of emotions and attitudes: the anticipation of an unpleasant event may generate a variety of emotional changes, such as fear or alarm which are not necessarily under voluntary control. Voluntary behaviour, that is, that directly affected by its consequences, is the sphere of operant conditioning.

conflict, social

Social conflict can be considered in two ways: as a perspective in which conflict permeates and shapes all aspects of human interaction and social structure, or as one of

innumerable specific fights or struggles such as wars, revolutions, strikes and uprisings.

Conflict perspective

Stated at a necessarily high level of generality, analysts using the conflict approach (as opposed to, say, a functionalist, exchange, or systems approach) seek to explain not only how social order is maintained despite great inequalities, but also how social structures change. They view societies, organizations, and other social systems as arenas for personal and group contests. (Complementary and common interests are not excluded, but the incompatible character of interests are emphasized.) Coercion is viewed as a major way in which people seek to advance their interests. It is assumed that humans generally do not want to be dominated or coerced, and therefore resist attempts at coercion, and struggles ensue.

Conflict theory has a long tradition going back to the earliest historical accounts and counsel to rulers, as can be seen in the writings of Thucydides, Machiavelli and Hobbes. Marx and Engels stressed the material conditions underlying conflict, especially the class struggles based upon property relations. Other conflict theorists such as Gumplowitz, Ratzenhofer and Novicow worked in the context of evolutionary thought and posited a group struggle for existence; they variously stressed military power in conflict, and interests—for example, ethnic differences—as bases for conquest. Simmel was another classical sociologist concerned with the forms and consequences of conflict.

Interest in the conflict perspective revived, at least in English-speaking countries, in the 1960s. In preceding decades the dominant social-science theories portrayed societies as based on consensus and consent, but the political turmoil of the 1960s, both domestic and international, directed attention to social conflicts and to the conflict approach.

Conflict theorists have emphasized different combinations of elements from the rich conflict tradition. Many contemporary social scientists draw from Marxism, but they differ a great deal in their interpretations of Marx and how they have developed elements of it. For example, Gramsci (1971) stresses the cultural hegemony of the ruling class as a mode of domination. Many conflict theorists stress their differences with Marxism, or otherwise emphasize authority, ethnicity, gender or other factors and processes which Marxists do not. For example, Dahrendorf (1959) argued that authority relations, not property relations, underlie social conflict. Collins (1975) considered coercion, including violence, as important means of control, but he also drew from the symbolic-interaction tradition to stress the importance of meanings in the organization of people for struggle, both at the interpersonal and the social-structural levels.

The study of economic development exemplifies how the conflict perspective has become important for many topics of enquiry. The conflict approach in this context stresses the use of economic, political, and military power to impose unequal exchanges which lead to a world-system marked by dependency; many analysts have sought to account for underdevelopment in the Third World using this perspective.

Types of social conflicts

Social scientists seek to understand specific conflicts in the context of interdependent relations and institutionalized means of changing relations. Many such kinds of conflicts have long been studied, as testified by the literature on wars, revolutions, labour strikes, communal riots and interpersonal fights. Social scientists have sought to develop explanations for social conflicts in general, examining their sources, patterns of escalation, de-escalation, settlement and consequences. There are important similarities among all kinds of conflicts as adversaries mutually define each other, perceive incompatible goals, strive to attain them, and resolve the conflict through various combinations of imposition and implicit and explicit negotiations. To specify such ideas, types of conflicts need to be distinguished. Variations in types of social conflicts affect the way they emerge, escalate, and deescalate. Among the many variations are three particularly significant and interrelated factors: the character of the parties, the nature of the goals, and the means used in the struggle.

First, conflicting parties differ in their degree of organization and boundedness. At one extreme are governments, trade unions and other entities with membership rules and generally recognized roles for forming and executing policy towards adversaries. At the other extreme are more nebulous entities such as social classes and believers in a common ideology where boundaries of adherence may be disputed or in flux, and which generally lack recognized roles for contending with adversaries. Moreover, every social conflict is likely to include many adversaries: some overlapping and cross-cutting, or encompassing others. For example, a government head may claim to speak for a government, a state, a people, an ideology, a political party faction, and a social class. Each such claim helps constitute a corresponding adversary. Herein lies one of the bases for the interlocking character of conflict.

Second, social conflicts are about incompatible goals, and the nature of these goals are another basis for distinguishing different kinds of conflicts. Adversaries may contest control over land, money, or other resources which they all value: such disputes are *consensual* conflicts. Alternatively, they may come into conflict about differently held values. These are *dissensual* conflicts. Of course, in specific conflicts both consensual and dissensual components are usually present. In addition, goals differ in their significance for the adversaries, e.g. whether they pertain to peripheral interests or to basic human needs.

Third, conflicts are waged in a variety of ways. Conflict analysts are usually interested in struggles involving violence or other forms of coercion, whether employed or threatened, and which are relatively non-institutionalized. But an adversary often uses persuasion and even the promise of rewards to influence the other side to agree to what is being sought. In many conflicts, the adversaries adhere to well-developed and highly institutionalized rules; indeed, these are often not regarded as social conflicts at all. This may be the case, for instance, in electoral campaigns, where different parties seek to control the government. Certain kinds of conflicts may become increasingly institutionalized and regulated over time, and that transformation is a matter of

paramount significance. We can recognize such a change in labour-management conflicts in many countries during the nineteenth century (Dahrendorf 1959).

Aside from the theoretical issues, the value orientations of the investigators are also crucial in the study of conflicts. Some tend to approach social conflict from a partisan perspective, trying to learn how to advance the goals of their side. This is the case for military strategists and many advocates of national liberation. Others want to minimize violence and look for alternative ways of defending or attaining their goals. Still others are primarily interested in attaining a new social order, justified in terms of universal claims for justice or equity; they may see conflicts as the natural process towards this end. Finally, the intellectually curious adopt a disinterested, relativistic view of social conflicts.

Such judgements of social conflicts are affected by a variety of social conditions, intellectual changes, and the course of major paradigm-shifting conflicts. For example, in the USA during the 1950s, conflicts were often viewed as unrealistic and disruptive and as instigated by socially marginal individuals; during the late 1960s and 1970s, they were often viewed as realistic efforts to redress injustices; in the 1980s, all contenders in a struggle tended to be accorded some legitimacy.

Origins of social conflicts

Social scientists mostly find the bases of social conflicts in social, political and economic relations and not in the biological nature of humans. But social conditions and processes internal to one party in a conflict may be stressed in accounting for a fight or for the means used in waging the struggle (Ross 1993). For example, feminists note the prevalence of gender role socialization which produces aggressiveness among men, and psychologists note that resentments arising from dissatisfaction from one source may be displaced upon easily targeted scapegoats. This produces an unrealistic conflict, in the sense that it is not based on objective conditions, or that the means employed are disproportionate to the issues at stake. It is difficult to assess the objective basis or appropriate means for solving a conflict, although various studies are contributing something in this direction.

Most conflict theorists stress that conflicts arise from adversaries striving for the same limited matters, and one underlying basis for such conflicts is inequality. Other conflicts may arise from differences in goals—when groups have different values but one group seeks to impose its own upon the other. In addition to differences which underlie the emergence of conflicts, the potential adversaries may have qualities which reduce the likelihood of a conflict erupting, such as high levels of interdependence and shared norms.

The system within which possible adversaries act can also effect the eruption of conflicts. The existence of legitimate means for managing conflicts usually reduces the likelihood of a conflict emerging. Functionalist theorists stressing the functional integration and consensual character of social systems, believe that many conflicts result from unequal rates of social change (Johnson 1966). Such conflicts tend to exhibit behaviour which analysts regard as expressive rather than instrumental.

Awareness by adversaries that they are in conflict is necessary for a conflict to exist. Some analysts argue that awareness arises from absolute deprivation, while others regard relative deprivation as more important (Gurr 1970). In any event, the group members' beliefs that they are able to improve their conditions are crucial, and these beliefs vary with developments in each contending party and in their relations with each other. The strength and cohesion of the dominant group is critical to the emergence and success of challengers to domination (Goldstone 1991). Groups seeking to change others must also be able to mobilize to pursue their goals (Tilly 1978). Pre-existing interpersonal linkages help mobilization, as do charismatic leaders and shared ideologies of possible recruits.

The fact that dominant groups are relatively able to attain their goals helps explain why they often initiate further demands leading to overt conflict. If a subordinate group believes that it can effectively challenge the status quo, the dominant group may react by attempting to suppress the challengers by persuading others to regard the status quo as legitimate.

Conflict escalation, de-escalation and settlement

Most studies of social conflicts have focused on the emergence of coercive behaviour and its escalation, but interest in conflict de-escalation and conflict resolution has grown. The coercive means used in waging a conflict vary greatly in intensity and extent, and non-coercive inducements are also used in conflicts. While coercion encompasses a variety of violent and non-violent means, non-coercion includes efforts at persuasion and positive sanctions, such as promised benefits (Kriesberg 1982). Escalation and de-escalation are affected by the internal developments in each of the adversary groups, the interaction between them, and the conduct of actors not initially involved in the conflict.

First, internal factors include various social-psychological processes and organizational developments which lead to an increasing commitment to the cause of the struggle. Sub-units engaged in the conflict may derive power, status and economic gains by building up their fighting resources, while those who suffer in the struggle, especially if they are much more severely affected than their adversaries, may become less committed.

Second, how adversaries interact significantly affects a conflict's development. Adversary actions can be provocatively hostile and hence escalating, or successfully intimidating and thereby de-escalating; or the actions can be conciliatory and thus de-escalating, or appeasing and thereby encouraging escalation. Many conditions affect which specific patterns of conduct have which effects (Kriesberg 1982).

Third, parties not initially involved in a conflict affect its course of development by joining in to advance their own interests or by setting limits to the conflict. Intermediaries can also mitigate the undesired aspects of conflicts by mediation, thus facilitating communication and providing face-saving options. Every fight ends, but the end may be the prelude to the next fight. An understanding of the nature of a conflict's conclusion is a critical aspect in the study of social conflicts.

Adversaries in conflicts generally evaluate the outcomes in terms of victories or defeats, wins or losses. In addition, mutual losses are likely, as a conflict destructively escalates. It is also possible, however, that mutual gains are achieved, because of the

interlocking character of conflicts and the reframing of a conflict to achieve a mutually beneficial settlement. The longer term and indirect consequences of social conflicts are also important. Functionalists point to the functions of social conflicts not only for the contending parties, but for the larger system in which the conflicts occur (Coser 1956). Analysts adopting a conflict perspective observe that not only are conflicts endemic, but also they are ways of bringing about needed changes.

conformity

Early attempts to explain the many uniformities observable in human social behaviour in terms of either a limited number of instincts (McDougall) or some general principle of learning such as imitation or suggestion (Tarde, Le Bon) proved to be unsatisfactory because they were essentially circular explanations. Research on conformity *per se* did not commence until the question of accounting for regularities in behaviour was tackled experimentally in the laboratory.

In the 1930s Sherif (1935) investigated, under laboratory conditions, the formation and

functioning of social norms. He chose a task, based on the autokinetic effect, for which there were no pre-established norms or standards which might aid his subjects in making their judgements. When a fixed point of light is viewed in an otherwise totally darkened room it will appear to move. Sherif's subjects had to estimate, in inches, the extent of this apparent movement. Individuals, making a series of such judgements alone, established their own particular norm. When several such individuals subsequently performed the task in each other's presence, a convergence in their estimates was noted, i.e. the emergence of a group norm. Other individuals, who made their initial estimates under group conditions, subsequently maintained the group norm when responding alone. It was Durkheim (1966) who had first identified the state of anomie or normlessness. Sherif, by selecting the autokinetic effect, was able to investigate scientifically this social phenomenon, and he demonstrated how a social norm acts as a frame of reference to guiding individual action.

Enlightened liberals, who value the autonomy of the individual, disliked a possible implication of Sherif's findings: that humans are gullible. In the early 1950s Asch hoped to demonstrate individual autonomy by removing the ambiguity in the stimuli to be judged. Naïve subjects in his experiment found themselves, on certain critical trials, in a minority of one when making simple judgements about the equivalence of length of lines (Asch 1956). They were unaware of the fact that the other participants were, in reality, stooges of the experimenter who, on the pre-selected trials, were unanimous in making a wrong choice. On each trial the naïve subject responded either last or last but one. On approximately two-thirds of the occasions when this conflict occurred, the naïve subject remained independent. So Asch had proved his point. Or had he? It was the minority response in the Asch situation, however, that riveted people's attention, i.e. yielding to the opinion of the false majority. Individuals differed quite widely in the extent to which they conformed. That naïve subjects should conform on as many as one-third of such occasions deeply shocked many Americans and also, one suspects, Asch himself.

The experiment had an immediate impact outside of Asch's own laboratory. Much was written, of a popular nature, about the prevalence of conformity in social life. By varying both the size and the unanimity of the false majority, Asch showed that the effect depended crucially upon the majority being unanimous and that it was maximal in strength with a majority of four. Crutchfield (1955) mechanized the Asch procedure by standardizing on a group of five and substituting electronic for live stooges. All five were naïve subjects, believing themselves to be subject number five. This greatly increased the efficiency of data collection without significantly reducing the level of conformity. Deutsch and Gerard (1955) increased the individual's independence in the Asch situation by either increasing the salience of self to self (by requiring subjects to note down their own responses *before* hearing the responses of the others) or by decreasing the salience of self to others (with anonymous responding).

Milgram's (1974) experimental studies of obedience were as controversial in the mid-1960s as Asch's studies had been in the early 1950s. Milgram identified the conditions conducive to the carrying out of instructions coming from a legitimate source of authority (i.e. the experimenter). In response to Asch's studies, Moscovici (1976) has developed a theory of minority influence. He is concerned with identifying how it is that minorities, over time, come to influence the majority. While his theory is based on laboratory

evidence, Moscovici is more broadly interested in how creative individuals (like Freud, Einstein or Darwin) manage to convert the majority to their own way of thinking. He is thus more interested in studying creativity and change than in studying the maintenance of the status quo.

connectionism

The term connectionism has been used in a variety of senses in the history of psychology. Carl Wernicke's (1874) model of language functioning, which emphasized connections between different areas of the brain, was dubbed connectionist, as was Donald Hebb's (1949) account of memory as the strengthening of neural connections. The modern use of the term is related to Hebb's, and applies to computational models of human performance that are built from neuron-like units. These models can be traced back to the work of McCulloch and Pitts (1943) on the simulation of neural functioning. Their ideas were simplified and made computationally viable by Rosenblatt (1962), in his work on *perceptions* in the 1950s and 1960s. However, interest in perceptrons waned when Minsky and Papert (1969) showed that the best understood perceptrons had severe limitations. In particular they could not solve so-called *exclusive-OR* problems, in which a stimulus was to be classified in a particular way if it had one property or another property, but not both. More complex perceptrons were difficult to analyse mathematically, but interest in them revived in the late 1970s, with the availability of cheap computer power. Such computer power enabled a practical, rather than a mathematical, demonstration of what problems could be solved by complex *neural networks.*

Since the mid-1980s neural network computing has seen a wide variety of applications,

most of which lie outside of psychology. The term connectionism, though not strictly defined, is usually applied to the use of neural networks in psychological models of a kind made popular by Rumelhart, McClelland, Hinton and others (McClelland *et al.* 1986; Rumelhart *et al.* 1986). A connectionist model contains three groups of neuron-like units called *input units, hidden units and output units.* The basic property of a unit is to have a *level of activation,* corresponding roughly to a rate of neural firing. Activation is passed along the connections that link the units into a network, so that the activation of a particular unit is affected (either positively or negatively) by the activation of the units it is linked to. Passing of activation takes place in a series of cycles, one at each tick of a (computational) clock.

The stimulus that a connectionist net is currently responding to is encoded as a pattern of activation in the input units. Cycles of activation passing lead to a pattern of activation in the output units, which encodes the net's response. The hidden units come between the input units and the output units, and allow considerable complexity both in the responses that the net can make and in the relations between the ways it responds to different stimuli.

It is possible to specify the function of units in a connectionist network and the strengths of the connections between them. For example, a unit in a word identification system might correspond to a letter *A* at the beginning of the word, and this unit will be highly activated by a word that actually begins with *A*. In addition, this unit will have strong positive connections to units that represent words beginning with *A*. However, one of the most important properties of connectionist networks is that they can *learn* to perform tasks. But, if they are to learn, all that can be specified is the methods of encoding used by the input and the output units. The interpretation of activation of the hidden units, and of the strengths of the connections between the units cannot be predetermined. In fact, learning in such systems is defined as a change in strength of the connections.

The best known method of learning in connectionist nets is *back propagation.* Initially the strengths of the connections are set at random, and an input is presented to the system. It produces a random output, but is told by its teacher (usually another part of the program) what the correct output should be. The difference between the actual output and the correct output is then used to adjust the strengths of the connections, working back from the output units to the input units (hence *back* propagation). This procedure is repeated many times for different inputs, selected from a so-called *training set.* The changes to the strengths of the connections are always (very) small, because the net must not get its response to the last input right by messing up its responses to other inputs. Eventually, a set of connection strengths should emerge that allows accurate response to all the stimuli in the training set and to other stimuli from the same class, on which it might be tested. Unsupervised methods of learning are also available for connectionist nets. *Competitive learning* is the best known in psychology, but a technique called *adaptive resonance* may be more useful.

Connectionist networks have found a variety of applications, both in psychological modelling and in the real world. In psychological modelling, the area that has seen the most successful application of pure connectionist techniques has been the identification of spoken and written words. In other domains, particularly those thought of as 'higher

level', *hybrid* models are more popular. These models combine connectionist techniques with more traditional symbolic ones. Interestingly, in commercial applications (see, e.g. Lisboa 1992), such as industrial process control (including robotics and machine vision) and pattern classification, hybrid system are also often used.

Although strong claims have been made for them, connectionist nets suffer certain limitations. First, despite their success in models of, in particular, spoken word identification, connectionist nets in their basic form are not able to represent sequential information in a natural way. However, the recurrent (or sequential) nets developed by Jordan (1986) do have this capability, since they feed information from the output units back to the input units (with a time delay), so that temporal sequences may be learned. A more important limitation is that current connectionist networks appear to be incapable of explaining some of the inevitable relations between bits of information stored in the human mind. As Fodor and Pylyshyn (1988:48) point out

> You don't…get minds that are prepared to infer *John went to the store* from *John and Mary and Susan and Sally went to the store* and from *John and Mary went to the store* but not from *John and Mary and Susan went to the store*.

Unfortunately it is all too easy for connectionist nets to have this property.

consciousness

Consciousness in the core sense refers to a state or continuum in which we are able to feel, think and perceive. Certain popular and social science usages, such as class consciousness, consciousness raising and self consciousness, refer to the content, style or objects of consciousness rather than the primary fact of being aware.

Consciousness is paradoxical because we have direct and immediate personal knowledge of it, but, at the same time, it seems to evade the explanatory frameworks of the social and natural sciences. Let us assume that it can be shown that a particular group of neurons in the brain fires whenever the observer sees something red, and that another group of neurons fires whenever the observer sees something green. This might explain how the observer can make different responses to different colours, but does not seem to explain the subjective appearance of those colours. Acquisition of the appropriate linguistic usages of the term red (as a child) might explain why we can all agree that ripe strawberries and English post boxes are red, but can it explain their redness? This point is illustrated in the puzzle of the inverted spectrum; suppose what you see as having the subjective quality of redness, I see as having the subjective quality of greenness. We nevertheless can agree in our use of colour names because the same (publicly describable) objects always cause similar (private) sensations for a given individual.

Philosophers have given the name *qualia* to specific sensory qualities, such as the smell of freshly baked bread, the sound of a breaking glass, or the colour and texture of the bark of an oak tree. To know these things vividly and precisely, it is not good enough to be told about them, one must experience them for oneself. Consciousness seems to depend on a privileged observer and unique viewpoint, and it might be argued that the subjective aspects of consciousness are thus outside the explanatory systems of science which are based on shared knowledge (Nagel 1986), and, by extension, beyond all socially constructed meanings.

William James (1890) provided a critique and synthesis of the nineteenth-century debate about whether the mind originated from the material brain or a nonmaterial soul. He concluded that thought was founded on brain physiology but followed its own laws. His analysis of consciousness began with introspection. Consciousness, or the stream of thought, is continuous and ever-changing. Thought is personal, related to an 'I' or self; it always has objects; it is selective and evaluative. Consciousness has a span: there are a limited number of objects which we can attend to simultaneously, and there is a span of immediate memory, for events which are just past and have not yet left consciousness.

Problems with introspection as a scientific tool contributed to the ascendancy of behaviourism from the 1920s to the 1950s. Behaviourists held that behaviour could be observed unambiguously, but mental states could not. Establishing the laws relating stimuli and responses would provide a complete explanation of behaviour, denying a causal status to mental events; consciousness was redundant.

With the growth of cognitive psychology in the 1960s, the causal status of mental events was re-affirmed; cognition (by analogy with computer programs) was identified as the processing of information received by the senses. It became legitimate to investigate such topics as mental imagery, objective measures such as reaction times providing corroboration of subjective reports. Much of cognitive processing, including early stages of perceptual analysis, was shown to be unavailable to consciousness, which was linked with focal attention.

Compelling evidence that consciousness depends upon specific brain functions comes from studies of patients with brain injuries. If the visual cortex on one side of the brain is destroyed following a stroke, vision is lost in the opposite half of the visual field. Such patients report a complete absence of any visual sensations from the blind hemifield. Some of these patients nevertheless can point, quite accurately, to a visual target in the 'blind' hemifield, while denying that they see anything. There is thus a dissociation between the conscious experience of seeing and the visual processing required for pointing; vision without conscious awareness is termed 'blindsight' (Weiskrantz 1986). If right parietal cortex is damaged, patients tend to exhibit a syndrome known as unilateral neglect. They appear not to be conscious of bodily or extra-personal space on the side opposite the lesion. The sensory input appears to be intact, because if a stimulus is applied in isolation to the neglected side, it can usually be detected. However, under everyday conditions patients may misjudge the centre of doors, eat only the right half of food on a plate or dress only the right half of the body. Bisiach and Luzzatti (1978) have shown that unilateral neglect applies to imagined as well as real scenes. It would appear that conscious awareness of an external world, of the body, and of an imagined scene, requires brain processes over and above the simple registration of sensory inputs. A key component of consciousness is deliberate or voluntary action: Luria (1973) described patients who, after massive frontal lobe lesions, were completely passive, expressed no wishes or desires and made no requests. Luria showed that this was a disturbance only of the higher forms of conscious activity, not a global paralysis or stupor. Involuntary or routine behaviours were intact or intensified, emerging sometimes at inappropriate moments, due to the loss of conscious regulation. Incidental stimuli such as the squeak of a door could not be ignored; a patient might respond involuntarily to an overheard conversation with another patient, while being unable to respond directly to questions.

Shallice (1982) has proposed that the frontal lobes are part of a supervisory attentional system which controls and modulates the routine, involuntary and habitual processes of behaviour and perception, and it is tempting to identify conscious thought with the normal operation of systems of this kind. Velmans (1992) has argued, however, that it is mistaken to abandon a first-person for a third-person perspective in this way, and that it is focal attention, not consciousness, which has a role in human information processing.

What are the developmental origins of consciousness? Vygotsky (1986) saw individual subjective awareness as secondary and derivative of social awareness; an internalization

of processes and concepts derived from the wider culture via speech (Kozulin 1990). In keeping with this view, the ability to monitor one's own experiences and the intentions of others are facets of the same developmental achievement (meta-representation). According to Perner (1991), children below the age of 4 years do not know that they have intentions: moreover, in solving a puzzle they did not know whether they chose the right answer because they knew it was correct, or by guessing.

Social and cognitive theories of consciousness are broadly compatible with a functionalist stance on the mind-body problem. Thus, Dennett (1991) has argued that enough is now known, from psychology, social sciences, neuroscience and computer science, to provide an explanation (in principle) of consciousness. Only the philosophers' puzzles remain, and Dennett marshals arguments to strip them of their power: qualia, for instance, are ultimately nothing more than the sum total of our reactive dispositions, and there is no Cartesian theatre where conscious events are played out for us.

Crick (1994) argues that a neurophysiology of consciousness is within the scope of science. It should be possible, for example, to identify the neural correlates of visual awareness. Neurons in higher visual areas, such as V4 and V5, have responses which correlate more closely with perceptual responses than do neurons in lower visual areas such as VI: V4 cells responding to colour patches are influenced in their firing by surrounding colour patches in a way that parallels human perception of colour; cells in VI tend simply to respond to the wavelength of light. Crick reviews evidence that 'back projections' from higher to lower visual areas are important in visual awareness; they may unify the isolated visual features which bottom-up, hierarchical analysis has identified.

The demystification of consciousness by such means is unlikely to satisfy everyone, and for many, the paradox endures. Penrose (1994), for example, implies that the primacy of conscious experience places it outside the functionalist paradigm. He explains with great clarity fundamental problems in the theory of computation and quantum physics, and argues (more obscurely) that there is a deep connection between these problems and that of consciousness.

conservation

Conservation is essentially a stockholding activity. Holding back today allows greater use tomorrow or perhaps 100 years hence. Economists' attention, and ours, is generally focused on natural phenomena—fish, oil, environmental quality and suchlike—although machines, literature and culture may also be conserved and many of the same principles apply.

The earth is finite, its resources and its ability to carry population and absorb pollution are limited. Some economists believe that continued growth in output and population will bring the world to these limits perhaps rather quickly. According to this view both non-renewable stocks (such as oils and metals) and renewable resources (for example, fish and land) will come under increasing and perhaps irreparable strain. Environmental damage (through erosion, build-up of carbon dioxide) will likewise become excessive, and habits of high consumption, once built up, will be difficult to break. Radical and Marxist economists often blame such problems on capitalism, even if the countries of eastern Europe appear to have fared equally badly.

A more characteristic view among economists is that *markets* provide adequate incentives to conservation. Resource use will be determined mainly by expected price movements and the discount rate. Scarcity involves high prices, expected scarcity expected high prices, increasing the advantage both of conserving the resource and of taking other resource-saving measures such as recycling and appropriate technical change. Only where market failure occurs is there perhaps cause to worry, and even then such failure may tend to excessive conservation. Moreover, market failure can generally be recognized and alleviated. Occasionally the view emerges that such difficulties present a challenge, which mighty humankind must and will overcome. Wise use of resources to build up capital and develop new techniques and skills may be a crucial part of this fight.

The 1973 oil crisis exhibited vividly the possibilities and dangers of a resource crisis. The sudden fourfold rise in oil prices caused worldwide disruption; the ensuing slumpflation (though doubtless partly due to earlier causes) has been an obvious disaster, economically, medically and socially. Even an oil-rich country like Britain has been depressed. Econometric studies have indicated great responsiveness to price, but building up slowly over decades as capital, technologies and habits change. It is the slowness of

these changes that has created the current crisis, while in the longer run technological changes may bring unwelcome side-effects.

Renewable resources (like fish) are constantly replenished by nature, hence permitting (up to a point) continued use without depletion. There is a maximum sustainable yield, although it may be desirable to hold yield below this level because of harvesting cost, or above it because of discounting. With non-renewable resources (like oil), use now precludes use later, although reserves can be extended by improved extraction techniques and by exploration. Metals are normally considered non-renewable, although recycling can extend their use.

The natural environment is another kind of resource. To some extent it is the concern of the rich, for example, as a source of landscape and recreational experiences. However, in this it differs little from other parts of market and indeed non-market systems. But not all environmental problems are of this type. Water pollution and air pollution damage those who live in the areas concerned—often the poor, as the rich can afford to move away (into conservation areas perhaps). Erosion, flooding and pesticides will affect everyone.

There are also international problems, such as global overheating and the excessive build-up of carbon dioxide leading to difficult-to-reverse melting of the polar ice caps and very extensive flooding. Problems associated with nuclear radiation are widely feared. There are two reasons for including population in this discussion: first, population size and growth are major determinants of problems of resources and environment; second, childbearing involves the characteristic externality problem of unpaid burdens on others, especially if fiscal help is given to large families. Currently the world's population is doubling every forty years. In some countries, such as China and Taiwan, dramatic downward shifts in birth rate are occurring. But elsewhere, as in India and most Muslim and Roman Catholic countries, signs of change are very weak. Even in most developed countries population growth continues, with particularly strong resource effects. The causes are complex and poorly understood, although cost has been found relevant.

Many factors underlie inadequate conservation (see Pearce 1976), for example, difficulties of prediction and the appropriate treatment of uncertainty. Particularly important are common access problems, applying not only to fishing, but also to forestry, hunting, extraction of oil and deep sea nodule mining, and to population growth. Tax regimes can be strongly anti-conservationist—childbearing and US mining are important examples. Another possible problem is that the discount rate used is too high, giving undue favour to the present; the difficulties here are, first, that this is an economy-wide problem, by no means confined to resources, and indeed some writers have used it to justify greater investment and faster growth; second, governments may hesitate to override the preferences of the current generation; and, third, more radical authors suggest that growth itself uses resources and damages the environment, although this is disputed.

Remedies are difficult to summarize. Characteristically those used (and supported by most non-economists) are regulations, whereas much of the economic debate is over the superiority of taxes. Regulations include net size, limited seasons and outright bans in fishing, limits or bans for pollution, including pesticides, and planning regulations for building and land use. The objection is that lack of discrimination leads to inefficiency;

sometimes extreme inefficiency, as when limited fishing seasons invite the multiplication of boats, which stand idle over the rest of the year. Direct controls also tend to be narrowly specific, leaving no incentive to achieve more than the specified cut-back or to undertake R&D to improve control. Fiscal measures are occasionally used but with little finesse, and subsidies or tax concessions (as for airlines, heavy industries or children) are generally preferred to taxes. More promising examples, such as fuel-saving subsidies and also the emerging systems of penalizing pollution in several European countries, incidentally (and unlike controls) generating substantial revenue. There are many other possible remedies, such as nationalization, diversification (often favoured by ecologists) indirect measures (recycling, durability and curbs on advertising and so on), auctioned rights (for example to cull a resource or to pollute), public expenditure (on sewage or agricultural infrastructure and so on), provision of information, including forecasts, and attempts to influence attitudes. As Baumol and Oates (1979) emphasize, each of these methods, or indeed various combinations, will be appropriate in particular circumstances.

conservatism

Conservatism is the doctrine that the reality of any society is to be found in its historical development, and therefore that the most reliable, though not the sole, guide for governments is caution in interfering with what has long been established. Clearly distinctive conservative doctrine emerged in the 1790s, in reaction to the rationalist projects of the French revolutionaries, and its classic statement is to to found in Edmund Burke's *Reflections on the Revolution in France* (1790). Burke's historical emphasis was itself the outcome of deep currents in European thought, currents rejecting abstract

reasoning as a method for understanding the human world. The sheer flamboyance of Burke's rhetoric was necessary to bring conservatism into the world, however, since the doctrine in its purest form consists of a few maxims of prudence (concerning the complexity of things and the wisdom of caution) which, in the intellectualist atmosphere of the last two centuries, make a poor showing against the seductive philosophical pretensions of modern ideologies. These competing doctrines claim to explain not only the activity of politics, but humankind and its place in the universe. Burke himself thought that this wider picture was supplied for us by religion, and thus he was prone to extend the reverence appropriate to divine things so that it embraced the established institutions of society. This fideist emphasis, however, ought not to conceal the fact that conservatism rests upon a deep scepticism about the ability of any human being, acting within the constraints of a present consciousness, to understand the daunting complexities of human life as it has developed over recorded time.

Conservatism construes society as something that grows, and conservatives prefer pruning leaves and branches to tearing up the roots. The latter view is taken by radicals who believe that nothing less than a revolutionary transformation both of society and of human beings themselves will serve to save us from what they believe to be a deeply unjust society. Generically, then, all are conservative who oppose the revolutionary transformation of society. Specifically, however, conservatism is one of three doctrinal partners, each of which may plausibly claim centrality in the European political tradition. One of these is liberalism, constituted by its allegiance to liberty and the values of reform, and the other is constitutional socialism, whose fundamental preoccupation with the problem of the poor leads it to construe all political problems as issues of realizing a truer community. Modern politics is a ceaseless dialogue between these three tendencies and movements.

Conservatism in this specific sense emerged from a split in the Whig Party in late eighteenth-century Britain, and it was only in the 1830s, when the present nomenclature of each of the three doctrines crystallized, that Tories began calling themselves 'conservatives'. This name failed to catch on in other countries, most notably perhaps the USA, where 'conservative' until recently connoted timidity and lack of enterprise. From the 1960s onwards, however, the tendency of American liberals (predominantly but not exclusively in the Democratic Party) to adopt socialist policies has provoked a reaction which calls itself 'neo-conservative' in testimony to its adherence to many classical liberal positions.

As it is conservative doctrine that political parties must respond to changing circumstances, it would be not merely futile but also paradoxical to discover a doctrinal essence in the changing attitudes of any particular Conservative party. Nevertheless, conservatism is not only a doctrine but also a human disposition; many conservative temperaments have influenced the British Conservative Party, whose response to the successive problems of the modern world may give some clue to conservatism. Under Disraeli it organized itself successfully to exploit successive nineteenth-century extensions of the franchise, and its electoral viability has since largely depended upon the allegiance of the figure known to political scientists as the 'Tory workingman'. In the latter part of the nineteenth century, it rode a tide of imperial emotion and economic protection and stood for the unity of the United Kingdom against attempts to grant self-

government to Ireland. Between the two world wars, Baldwin saw it as the task of the party to educate an electorate, now enjoying universal suffrage, in the responsibilities of power. After Attlee's creation of the Welfare State from 1945 to 1951, Churchill and Macmillan found conservative reasons for sustaining a welfarist consensus, but since 1976, Mrs Thatcher and a dominant wing of the party identified the expense of the welfare state in its present form as one of the emerging problems of politics.

A principle of conservation offers little substantive guide to political action, and is vulnerable to the objection brought by F.A.Hayek: 'By its nature, it cannot offer an alternative to the direction we are moving' (*The Constitution of Liberty,* 1960). It is a mistake, however, to identify conservatism with hostility to change; the point is rather the *source* of change. It is characteristic of all radicals to seek one big change, after which a perfected community will be essentially changeless. On this basis, they often seek to monopolize the rhetoric of change. Liberals consider it the duty of an active government to make the reforms that will dissipate social evils. While refusing to erect limitation of government into an absolute principle, conservatives tend to think that, within a strong framework of laws, society will often work out for itself a better response to evils than can be found in the necessary complexities of legislation, and worse, of course, in the simple *dictat* of the legislator. Conservatism is, in this respect, a political application of the legal maxim that hard cases make bad law. It is thus a central mistake to think of conservatism as mere hostility to change. It poses, rather, the issue of where change should originate.

Like all political doctrines, conservatism is loosely but importantly associated with a particular temperament, a view of the world. It is characteristic of the conservative temperament to value established identities, to praise habit and to respect prejudice, not because it is irrational, but because such things anchor the darting impulses of human beings in solidities of custom which we often do not begin to value until we are already losing them. Radicalism often generates youth movements, while conservatism is a disposition found among the mature, who have discovered what it is in life they most value. The ideological cast of contemporary thought has provoked some writers to present conservatism as if it contained the entire sum of political wisdom; but this is to mistake the part for the whole. Nevertheless, a society without a strong element of conservatism could hardly be anything but impossibly giddy.

constitutional psychology

Constitutional psychology is an obvious and widely accepted feature of psychological thinking. At the same time it is a controversial view held by relatively few psychologists. It may be defined as the study of the relation between, on the one hand, the morphological structure and the physiological function of the body and, on the other hand, psychological and social functioning. Few psychologists would disagree with the idea that bodily structure and functioning are related to psychosocial functioning, and in fact considerable data support this relation (see e.g. Lerner and Jovanovic 1990).

The early work of Kretschmer (1921) and the later, more comprehensive research of Sheldon (e.g. 1940) were criticized on conceptual, methodological and data analytic grounds (Humphreys 1957). The scientific community had little confidence in the strengths of association between physique type and temperament reported in this work (e.g. correlations on the order of +0.8 between theoretically related physique and temperament types; Sheldon 1940). However, more methodologically careful work has established that significant associations do exist between somatotypes (endomorphs, mesomorphs, and ectomorphs) and/or other features of the body (such as physical attractiveness), and personality or temperament characteristics theoretically related to these somatotypes (e.g. viscerotonic traits, somatotonic traits and cerebrotonic traits, respectively) or to the other bodily features, for example physically attractive children and adolescents are more popular with peers than are their physically unattractive counterparts (Lerner 1987). But the strengths of the association are considerably less than that reported by Sheldon; for example, correlations more typically cluster around +0.3 (e.g. Lerner *et al.* 1991). Moreover, research relating pubertal change (such as early, on-time, and late maturation) to psychosocial functioning during adolescence has also established that significant relations exist between physiological (such as hormonal) changes or morphological characteristics and youth behaviour and development (Adams *et al.* 1992).

The controversy involved in constitutional psychology surrounds the explanation of the empirical relations between bodily characteristics and psychosocial functions. These explanations involve the well-known nature-nurture controversy. Only a minority of psychologists working in this area subscribe to nature-based interpretations of body-behaviour relations. Such interpretations stress that hereditary and/or other biological variables provide a common source of morphology, physiology and psychosocial functioning. For example, the biological variables thought to provide the source of a mesomorphic somatotype are thought also to provide the source of aggressive or delinquent behaviours (Hall and Lindzey 1978). Nurture-based explanations of body-

behaviour relations stress that environmental events (for example, socialization experiences) influence both bodily and behavioural characteristics (e.g. McCandless 1970). An example of this type of interpretation is that the socialization experiences that lead to a chubby body build also will lead to dependency and/or self-indulgence (Hall and Lindzey 1978).

Finally, most contemporary interpretations propose that biological and experiential variables interact or fuse to provide a basis of physical, physiological and psychosocial characteristics (see, e.g. Adams *et al.* 1992; Lerner 1987; 1992). A representative idea here, one associated with a 'developmental contextual' theory of human development (Lerner, 1992), is that children with different physical characteristics evoke differential reactions in significant others, and that these reactions feed back to children and provide a differential basis for their further psychosocial functioning; this functioning includes personality and social behaviour and also self-management behaviours (e.g. in regard to diet and exercise) which may influence their physical characteristics.

However, there are still no crucial or critical tests of key hypotheses derived from any of the extant interpretative positions. Indeed, data in this area, although increasingly more often theoretically derived from various instances of interactionist theory, are still typically open to alternative explanations (cf. Adams, *et al.* 1992 versus Lerner 1992). Nevertheless, activity in this area of research continues to be high, especially in research on the adolescent period of life (Adams *et al.* 1992; Lerner 1987; 1992). It is likely that the theoretical debates framing this activity will continue to promote research for some time.

constitutionalism

see **constitutions and constitutionalism**

constitutions and constitutionalism

The constitution of a state is the collection of rules and principles according to which a state is governed. In antiquity the most important function of a constitution was to determine who should rule. The criterion which served as the basis for assigning political power reflected the ethos of the society. Thus each constitutional form exercised a moulding influence on virtue; the good citizen was a different being in an oligarchy, a democracy and an aristocracy (Aristotle). Although modern constitutions are far more complex, still the rules they establish for acquiring and exercising governmental power will usually embody the underlying norms and ideology of the polity.

The constitution of the modern nation state contains three main elements. First, it establishes the principal institutions of government and the relationships among these institutions. These institutions may be structured on traditional western lines of a division of executive, legislative and judicial responsibilities. The constitutions of one-party states gives greater emphasis to the structures of the governing party, while those based on theocratic principles assign a dominant position to religious offices and institutions. Second, constitutions provide for a distribution of governmental power over the nation's territory. In a unitary state, local units of government are established as agencies of the central government. The constitution of a federal state assigns power directly to central and local levels of government. Third, constitutions provide a compendium of fundamental rights and duties of citizens including their rights to participate in the institutions of government. Some constitutions emphasize economic and social rights as much, if not more, than political and legal/procedural rights.

In most countries there is a single document called 'The Constitution' which contains

most of the significant elements of the constitutional system. But this is not the only form in which the rules of a constitution may be expressed. They may also take the form of ordinary laws such as statutes or decrees, judicial decisions or well-established customs and conventions. The United Kingdom is distinctive in that it does not have a document known as the Constitution; all of its constitutional rules are expressed more informally as statutes, judicial opinions, customs and conventions. Since the American Revolution the worldwide trend has been very much towards the codification of constitutional norms. New states established in the aftermath of revolution, the withdrawal of empire and world war have relied on a formal constitutional text to set out their basic governmental arrangements. However, even in these new nations, statutes, judicial decisions and conventions usually supplement the formal constitution.

A country may have a constitution but may not enjoy constitutionalism. Constitutionalism is a political condition in which the constitution functions as an effective and significant limit on government. Where constitutionalism characterizes a regime, the constitution is antecedent to government, and those who govern are constrained by its terms. The constitutional rules of such a regime are not easily changed—even when they are obstacles to policies supported by leading politicians. Thus, constitutional government is said to be 'limited government' (Sartori 1956). The limits imposed by a constitution are sometimes said to embody a 'higher law'—the enduring will of a people—which constitutes the basis of a legitimate check on the will of governments representing transient majorities (Corwin 1955; Mcllwain 1947).

Constitutionalism may be maintained by the practice of judicial review, whereby judges with a reasonable degree of independence of the other branches of government have the authority to veto laws and activities of government on the grounds that they conflict with the constitution. Constitutionalism in the European Union has been largely promoted by the European Court of Justice, whose decisions have given the treaties on which the Union is based the status of constitutional law with supremacy over the laws of the member states (Mancini 1991). Constitutionalism may also be manifest in a formal amendment process that requires much more than the support of a dominant political party or a simple majority of the population to change the formal constitution. The British situation demonstrates, however, that neither of these practices is a necessary condition for constitutionalism. In that country the most important constitutional precepts are maintained and enforced more informally through well-established popular attitudes and the restraint of politicians (Dicey 1959).

The reality of constitutionalism depends on whether there are political forces genuinely independent of the government of the day powerful enough to insist on the government's observance of constitutional limits. Critics of those liberal democracies that claim to practise constitutionalism contend that in reality the constitutions imposing constitutional limits (e.g. the judiciary or the opposition party) are not independent of government, because they are controlled by social or economic interests aligned with the government. However, defenders of these regimes may point to occasions on which the maintenance of constitutional rules has forced political leaders to abandon major policies or even to abandon office (e.g. US President Nixon in the Watergate affair).

In countries that have formal written constitutions, whether or not they practise constitutionalism, the constitution may serve an important symbolic function.

Constitutions are often employed as instruments of political education designed to inculcate public respect for political and social norms. A constitution may also be a means of gaining legitimacy, both internally and externally, for a regime. This is a primary function of constitutions in communist states (Brunner 1977). The development of codes of fundamental human rights since the Second World War has prompted many states to include such rights in their domestic constitutions in order to ingratiate themselves in the international community.

consumer behaviour

In his authoritative review of the development of utility theory, Stigler (1950) wrote, 'If consumers do not buy less of a commodity when their incomes rise, they will surely buy less when the price of the commodity rises. This was the chief product—so far as the hypotheses on economic behaviour go of the long labours of a very large number of able economists [who] had known all along that demand curves have negative slopes, quite independently of their utility theorizing.' So what use is utility theory, the reigning paradigm among economists interested in consumer behaviour?

Data on consumer behaviour have expanded enormously since the 1950s, computing costs have plummetted, statistical numeracy has spread and the range of applied studies has multiplied. Simultaneously more content has been put into choice theory and more accessible links forged via the cost and other 'dual' functions between the structure of preferences and behaviour. A comprehensive modern treatment of choice theory and its application to most types of consumer behaviour can be found in Deaton and Muellbauer (1980).

The existence of an ordinal utility function defined on bundles of goods implies that certain axioms of choice are fulfilled, the key ones being transitivity or consistency of choice, continuity (small differences matter only a little) and non-satiation. Preferences can also be represented through the cost function. This defines the minimum cost of reaching a given utility level for a consumer facing given prices. Among its properties: it is concave in prices and its price derivatives give purchases as functions of prices and the utility level, i.e. compensated demands. The great advantage is that a simple step— differentiation—leads from a representation of preferences to a description of the behaviour of a consumer faced with a linear budget constraint. Concavity then immediately implies the law of demand described above. In fact, considerably more is implied: the matrix of compensated price derivatives is symmetric negative semidefinite. A great deal of econometric effort has gone into applying and testing these very considerable restrictions on behaviour.

Systems of demand equations are usually estimated for annual or quarterly observations on aggregate consumer spending on such categories as food, clothing, housing, fuel, etc. More is now understood about the links between individual and aggregate behaviour. For example, under quite restrictive conditions, average behaviour is like that of a single consumer so that then one can say a 'representative consumer' exists. Specific assumptions on the structure of preferences yield further implications. Thus an additive utility function strongly restricts the cross-price responses of demands. These and many other properties are analysed in Gorman (1976), who makes elegant use of cost and profit functions. Almost invariably, some kind of separability assumptions are made in applied work: thus, preferences for current period goods need to be separable from the allocation of leisure and of consumption in other periods if demands are functions only of current prices and total expenditure on these goods. However, such static demand functions are, by most empirical evidence, mis-specified. A widely applied hypothesis which can explain why is that preferences are conditioned by past behaviour, not only of the consumer but also of others, so that demand functions are dynamic (more on this below).

By assuming that the consumer can lend or borrow at the same interest rate, the utility maximizing consumer's inter-temporal choices are subject to a linear budget constraint. In this life-cycle theory of consumption, developed by Modigliani and his co-workers, the budget is life-cycle wealth consisting of initial asset holdings, income and discounted expected income, and relative prices depend on real interest rates. Extensions to the demand for money and durables have yielded interesting insights into, for example, the role of interest rates.

The treatment of income expectations has been the most controversial issue for empirical workers using this theory. The simple treatment by Friedman in his book on the

permanent income hypothesis of consumption, as well as his suppression of a separate role for assets, is now seen as less than satisfactory. Hall (1978) has shown that, under certain conditions, the life cycle model together with rational expectations implies that consumption follows a random walk. There is significant empirical evidence against both the random walk hypothesis and simple forms of the life cycle model (see Deaton 1992).

One of the major criticisms of life cycle theory is that the budget constraints are not in fact linear for credit constrained consumers, though the implications are hard to model on aggregate data. Much attention has been paid to non-linear budget constraints in the analysis of behaviour from household surveys. Labour supply decisions are the major example; others are the choice of housing tenure and transport models where choice has discrete elements. An integrated statistical framework with rational and random elements for such decisions now exists. In this context too, restrictions on preferences have major empirical content, for example, additive preferences allow great simplifications in the analysis of repeated surveys of the same households. A more traditional use of household budget surveys collected to derive weights for cost of living indices and to analyse inequality has been the derivation of Engel functions which link expenditures on different goods with the total budget and household demography. A major use has been derivation of equivalence scales used to standardize budgets in studies of poverty and inequality for variations in household size and structure.

Another way to put more content into the theory is to regard the household as a producer, using market goods and time, of utility yielding commodities. This household production approach has proved useful, for example, in the measurement of quality change, in welfare measurement of the provision of public leisure facilities, and in the economics of fertility and other aspects of family life. There has been increasing interest in how decisions by individual family members are co-ordinated.

Most decisions are, of course, made under uncertainty and the expected utility approach has been widely used by economists. Under the axioms assumed here, subjective probabilities are themselves defined and this gives rise to a theory of learning founded on Bayes' Theorem. The intuitive notion of risk averting behaviour here has a formal basis and applications to the behaviour of financial markets have proved particularly popular. Evidence against some of the axioms has accumulated from laboratory experiments on volunteers. So far no agreement exists on a better set of axioms.

There have been many criticisms of the utility maximizing approach, ranging from 'it is tautologous' to the introspective doubt that anyone could be so good at absorbing and storing information and then computing consistent decisions. H.A.Simon's notion of bounded rationality has much intuitive appeal. Certainly one can interpret the role of costs of adjustment or habits based on own or others' behaviour in this light. The implication of a stimulus response smaller in the short run than in the long is suggestive. Psychologists have suggested models such as that of 'cognitive dissonance' which appeal in particular contexts but do not yield a general behavioural theory. Market researchers have developed distinct approaches of their own based on the interpretation of attitude surveys used as marketing tools and with the major focus on brand choice, repeat buying and the introduction of new varieties. They have drawn relatively little out of the utility maximizing hypothesis, though not all these approaches are necessarily inconsistent with

it.

consumer surplus

There can be few areas of economics where more ink has been spilled in obfuscating an essentially simple idea. The basic idea of the change in consumer surplus is to measure the loss or gain to a consumer from a change in consumption or from a change in one or more prices. The early formulation by Dupuit in 1844 was justified by Marshall in 1880. It consists of taking the area under the demand curve which traces out the effect of changes in the good's price, holding constant the budget in order to measure the change in utility in money terms. Already in 1892 Pareto criticized Marshall's assumption of a constant marginal utility of the budget. Indeed, there are only two circumstances where Marshall's formulation is correct: either the proportions in which goods are consumed are independent of the budget, which is grossly untrue empirically, or, for the particular good whose price is changing, the demand is unaffected by changes in the budget.

Hicks in 1939 recognized that the correct measure is to take the change in area under the compensated demand curve. However, as Samuelson remarked in 1947, consumer surplus was essentially a superfluous concept since there was already an established theory of economic index numbers. The modern theory of index numbers is based on the cost or expenditure function which gives the minimum cost of reaching a given indifference curve at a specified set of prices. The money value of a change in utility is then given by the change in cost at some reference prices. When the change in utility is caused by some price changes, Hicks's 'compensating variation' can be viewed as the measure which uses the new prices as reference and his 'equivalent variation' as that which uses the old prices as reference.

There is a widespread impression that the computation of such correct concepts is intrinsically harder or requires more information than computing Marshallian consumer surplus. However, simple and accurate approximations to the correct measures are

available, and straightforward algorithms exist to calculate them with any required degree of accuracy. Finally, it should be noted that *aggregating* utility changes over different consumers raises a new issue: is a dollar to the poor worth the same in social terms as a dollar to the rich? Consumer surplus as such does not address this question, though it is an inescapable one in cost benefit analysis.

consumption function

The consumption function expresses the functional dependence of consumption on variables thought to influence the level of consumption expenditure by individuals, such as income, wealth and the rate of interest. The consumption function was an important innovation introduced into economic theory by J.M. Keynes in his *General Theory of Employment, Interest and Money* (1936), to undermine the classical orthodoxy that the rate of interest acts to equilibrate savings and investment at the full employment level of income. Keynes made consumption, and therefore saving, a function of income, and by doing so divorced the savings function from the investment function. He then showed that if plans to invest fall short of plans to save out of the full employment level of income, there will be a tendency for the level of income (not the rate of interest) to fall to bring saving and investment into equilibrium again, the extent of the fall being given by the value of the income multiplier which is the reciprocal of the marginal propensity to save. By means of the consumption function, Keynes had apparently demonstrated the possibility that an economy may find itself in an equilibrium state at less than full employment. This demonstration was part of the Keynesian revolution of thought which undermined the idea that there are macroeconomic forces at work which automatically guarantee that economies tend to long-run full employment. This is the theoretical importance of the consumption function.

The practical interest in the consumption function relates to the relation between consumption and income through time. Keynes seemed to suggest that the long-run consumption function was non-proportional, so that as societies became richer they would spend proportionately less on consumption, implying that a higher proportion of income would have to be invested if economies were not to stagnate. Fears were expressed that mature economic societies might run out of profitable investment opportunities. The international cross-section evidence reveals an interesting pattern. The savings ratio does rise with the level of development but at a decreasing rate, levelling off

in maturity at about 25 per cent of national income. There is a voluminous literature concerning why this should be the case. It is as if saving is a luxury good which then loses its appeal. James Duesenberry (1949) developed the relative income hypothesis, which predicts that the savings-income ratio will remain unchanged through time if the personal distribution of income remains unchanged. Ando and Modigliani (1963) developed the life-cycle hypothesis of saving, which predicts a constant savings ratio if the rate of growth of population and per capita income are steady. Milton Friedman (1957) developed the permanent income hypothesis, arguing that individuals wish to maintain a constant relation between their consumption and a measure of permanent income determined by wealth and other factors. To discriminate between the hypotheses is virtually impossible. As societies develop, both growth and income inequality first increase and then decelerate and stabilize, which would explain the historical savings behaviour observed. Other factors that might be important relate to the increased monetization of an economy, which then yields diminishing returns. However, the fears of a lack of investment opportunities to match growing saving, owing to the saturation of markets, seems to be unfounded.

co-operatives

Co-operatives are economic organizations run by their members on the basis of one person, one vote, with their trading surplus being distributed among the membership in an agreed manner. Membership can therefore be seen as an extension of corporate shareholding except that, in co-operatives, decision making is based on democratic principles. Hence the defining characteristic of the co-operative is the principle of one member, one vote. Unlike conventional firms, a capital stake is not necessarily the crucial element conferring decision-making rights. Indeed, the return on capital holdings is generally fixed at a low level, leaving the bulk of the surplus to be allocated according to member transactions. Decision-making authority derives from the characteristic of the democratic collective, such as consumers, farmers or workers. For example, in consumer co-operatives, membership derives from the act of purchase and profits are distributed according to the amount spent. In agricultural co-ops, the members are private farmers who join forces for production, retailing and services. Other important co-operative forms include credit unions and housing co-operatives, in which the membership are borrowers and lenders and tenants respectively, and producer co-operatives, in which the workers jointly share the profits as income.

In 1844 the first co-operative was opened in Toad Lane, Rochdale, by twenty-eight Lancashire workers, who developed the seven 'Co-operative Principles' which still form the basis of the international co-operative movement. These are open membership; one member, one vote; limited return on capital; allocation of surplus in proportion to member transactions; cash trading; stress on education; and religious and political neutrality. They were reviewed by the International Co-operative Alliance (ICA), the worldwide organization of all co-ops, in 1966, and the last two principles were dropped in favour of a new one supporting inter-co-operative collaboration.

The international co-operative movement has grown to enormous proportions, with more than 700,000 co-operatives affiliated to the 1C A in 1980 containing 350 million members in 65 countries. The largest number of societies were agricultural and credit co-operatives, with 250,000 each worldwide covering 180 million members between them. However, the largest number of members are in consumer co-operatives, containing 130 million in 60,000 societies. There are also 45,000 industrial co-operatives with a labour force in excess of 5.5 million workers. Co-operatives started in Europe and North America and the movement still has a solid basis there, especially consumer and agricultural co-operatives. Since the Second World War there has been rapid expansion of the co-operative movement in less developed countries, where agricultural co-operatives, for example, allow smallholders to combine their resources for harvesting, production or marketing. The co-operative form has become significant in the former communist countries of central and eastern Europe, representing a compromise between the socialist and capitalist form of work organization.

Inspired by the system of workers' self-management of industry that operated in

former Yugoslavia between 1952 and 1989, and following the seminal work of Ward (1958) and Vanek (1970), these producer co-oper-atives, or labour-managed firms as they have become known, have been studied extensively (see Ireland and Law 1982 for a survey). Analysts interested in how enterprise decisions change when the interests of workers replace profitability as the corporate objective, have focused on five main areas. First, it has been argued that producer co-operatives are not very market-oriented firms, and may have sluggish or even perverse production responses because the membership's motivation is to increase wages and secure employment rather than to increase profit by satisfying consumer demand. Second, it is feared that such firms will under-invest, because workers will prefer higher wages now to future income increases to be obtained through investment. Third, many observers have suggested that there will be deficiencies in managerial competence and an unwillingness to bear risks. These factors together indicate that producer co-operatives might find it difficult to survive in a free market environment, a view encapsulated in the fourth proposition that producer co-operatives are founded to secure jobs in declining sectors, but when conditions improve they degenerate back to the capitalist form. Such a pessimistic argument is often countered by the final observation that employee involvement in decision making and profits can act as a decisive boost to labour productivity. This has stimulated interest in schemes for worker participation in management as a way of obtaining the positive incentive effects without the presumed deficiencies of full workers' control.

There are producer co-operative sectors in most western economies, the largest and most successful being the Mondragon group in the Basque area of Spain. Since its formation in the mid-1950s, an integrated productive, retail, financial and educational structure has emerged providing 16,000 industrial jobs. Empirical work establishes the group to be relatively more productive and profitable than comparable capitalist firms, as well as being better able to meet social goals (see H.Thomas in Jones and Svejnar, 1982). Other studies isolate a positive productivity effect in the 20,000 Italian producer co-operatives, the 700 French ones and the 800 societies in the USA (Estrin *et al.* 1987). However, apart from Mondragon, producer cooperative have tended to be relatively small, under-capitalized, concentrated in traditional sectors like textiles and construction, and short lived. The co-operative form has probably failed to displace joint stock companies despite their democratic structure and the productivity benefits because of difficulties with risk bearing; entrepreneurial workers cannot spread their risks by working in a number of activities in the way that capital owners can spread theirs by holding a diversified portfolio of assets. Hence capital has historically hired workers rather than labour hiring capital. However, many new producer co-operatives have been founded as a way of maintaining employment—about 1600 in the UK between 1975 and 1990—and if risk-bearing problems can be solved this may prove to be an important type of enterprise in the future.

corporate enterprise

The most common form of capitalist business enterprise, the limited liability company, has a legal status or a *persona* separate from owners or shareholders. Three features arise: debts incurred are the firm's, not the shareholders', whose maximum liability is restricted to their original financial outlay; the identity of the firm is unchanged should any shareholders transfer their ownership title to a third party; contractual relations are entered into by the firm's directors.

It is widely agreed that the move to large-scale industrial enterprise was facilitated, and indeed made possible, by limited liability. The threat of potential confiscation of an individual's total wealth should part of it be invested in an unsuccessful company was removed. Moreover risk could be further reduced by investing in several and not just one firm. Large sums of untapped personal financial capital became available after the advent of limited liability. Transferability of shares permitted continuity of business operation not present in other forms of enterprise. The existence of the firm as a separate contracting *persona* permitted a productive division of labour between risk-bearing capitalist and business administrators.

Schumpeter (1950) criticized this division of labour as 'absentee ownership' which pushes 'into the background all…the institutions of property and free contracting…that expressed the needs of economic activity'. Others, such as Hessen (1979), take the contrary view: limited liability and the joint stock firm are creatures of private agreement, not the state. Freely negotiated contractual specialization is a device for greater efficiency in meeting private wants, not a shirking of responsibility.

Historically limited liability was a state-created benefit awarded by fifteenth-century English law to monastic communities and trade guilds for commonly held property. Likewise in the seventeenth century, joint stock charters were awarded as circumscribed

monopoly privileges to groups such as the East India and Hudson's Bay Companies. The two properties were amalgamated by a 1662 Act of Parliament (Clapham 1957). Many entrepreneurs, banned by law from adopting the corporate form, simply copied it using the common law provisions of transferable partnership interests alone or together with those of trusteeship. Indeed it was through those mechanisms that the British canal and railway systems were financed and managed in the 1780s-90s and the 1830s-40s respectively. The Bubble Act 1720, which was passed to suppress such innovations, failed (Du Bois 1938) and in 1844 the Companies' Registration Act effectively repealed it, setting up a registry for corporations which made their establishment cheap and easy; the state's role became simply that of a recording agency. The 1844 Act was amended in 1856 to provide limited liability to all registered companies. Thus it could be argued that either the selective legal privilege of limited liability was extended to all or alternatively that legislation was merely catching up with the reality in the financial market-place, namely that the characteristics of the corporation appeared without the need for government intervention. Nevertheless, corporations appeared in large numbers after the institution of limited liability. Prior to that, and still numerically important in the 1990s, most businesses were conducted by sole traders and unlimited partnerships of two or more people. Incorporation encouraged firm growth and, except in the smallest corporations, shareholders participated less in day-to-day management. In the UK this growth continued well into the twentieth century resulting in an increasing concentration of industry.

Firms initially grew to obtain the advantages of scale economies and of monopoly power. The latter was perceived to be especially true in the USA where men like Rockefeller and Carnegie built industrial empires in the oil and steel industries. Congress, fearful of the consequences of industrial size, passed the Sherman Anti-trust Act in 1890, and firms such as Standard Oil and American Tobacco were ordered to divest themselves of assets and split into separate firms. In the next three-quarters of a century many US firms took alternative growth routes, partly to minimize their visibility to trust-busters and partly to obtain the benefit of diversification. Risk-avoidance was obtained by spreading the company's efforts over a range of domestic markets for different products, or by expanding abroad with the original product range. These activities were mirrored elswhere by British, German, Dutch and Swiss firms such as ICI, Hoechst, Philips and Nestle respectively.

Some observers are concerned at the levels of industrial concentration. They argue that as a consequence prices are uncompetitively high, that very large firms become inefficient and reluctant to change and innovate. Others argue that concentration varies industry by industry and is determined by technology or is a reward for innovation and efficiency. Large firms become large only by winning the consumer's approval. The leading firms are also changing and the leading 100 firms of 1900 were very different in both identity and in ranking from the leading 100 in 1990. Firms must either change as demand and supply conditions change or forfeit any position they have won through previous successful responsiveness to market conditions. This view holds that provided entry to and exit from an industry are easy, concentration levels need not be a cause for concern. The issue of whether industrial structure determines firm conduct and performance, or whether firm performance and conduct determines industrial structure, is

still unsettled. If there are barriers to entry imposed by regulations, the truth may embody both theses.

A further area of debate is the degree to which incorporation and what Berle and Means (1968) called the consequential 'divorce of ownership from control' has resulted in managers pursuing goals different from the maximization of profit. Alternative theories have been put forward suggesting that managers pursue sales or asset growth, size *per se,* or maximize utility functions containing both financial and psychic variables. In most cases these alternative goals are subject to a minimum profit constraint which, if not met, would result in a takeover by another firm, loss of managerial job security and so a return to a profit target closer to that of maximization. Proponents of these views argue that these alternative goals result in different patterns of firm behaviour if the external environment changes (for example, a flat rate tax on profits does not affect a profit maximizer's behaviour, but a sales maximizer subject to a minimum profits constraint would reduce output and raise price). Defenders of the traditional theory (such as Manne 1965) argue that efficient stock markets, via the takeover mechanism, ensure that managers depart but little from profit maximization. To the extent that they do, this is a cost borne willingly by owners to achieve the net benefits of specialization of function between risk capital providers and the more risk-averse providers of managerial expertise.

The issue then becomes one of how best to minimize this agency cost (Jensen and Meckling 1976). In countries such as Sweden, Switzerland and South Africa, pyramidal holding companies controlled by a few dominant shareholders are common. Proprietorial family groups such as the Wallenbergs or the Oppenheimers control an array of companies while owning only a small percentage of the total capital. But this small fraction notwithstanding, it represents a large proportion of the proprietors' wealth, motivating them to control management rather than to sell out if the companies controlled are not run in the proprietors' interests.

In Anglo-Saxon countries, such as the UK and the USA such forms of corporate control are either discour-aged or illegal. Roe (1991) documents the history of legal and political restraints on the control of US corporations by financial institutions such as J.P.Morgan at the turn of the century and others such as insurers, banks and unit trusts today. Black and Coffee (1993) argue that similar less formal restraints were placed on British bank ownership of shares by the Bank of England, and that while UK institutions have been major shareholders for some decades they have been reactive rather than proactive owners. Thus the divorce of ownership from control in Anglo-Saxon countries, where not offset by the takeover mechanism, is, on this view, exaggerated—by governmentally created constraints and prohibitions on minority proprietorial ownership structures which give disproportionate power to such owners, or by constraints on bank and institutional ownership, or by the 'free-rider' problem. (Thus an institution with 5 per cent of shares acting on its own to improve corporate performance would gain 5 per cent of the benefits, the remaining shareholders would reap the remaining benefits while incurring none of the costs.)

corporatism

Corporatism, whether corporate, clerical or fascist in origin, is an ideology of organization which assumes that a variety of parties will co-operate on the basis of shared values. Corporatism (also called neo-corporatism or liberal corporatism) presupposes, on the contrary, the existence of fundamental conflicts which, however, need not produce organizational disruption but can be mediated with the help of the state. The concept first appeared in Scandinavian writings after the Second World War (Heckscher, St Rokkan), but was only made generally known by Schmitter (1979; 1981). However, functional equivalents of the concept, labelled 'organized capitalism' can be traced back to Hilferding (1915) in the social democratic debate in Germany and Austria. The concept was thus developed in countries where state sponsorship of trade unions had a certain tradition, but where unions had achieved positions of considerable power.

Corporatism has been greatly extended. Left-wing theorists invoke it to explain how—despite expectations—through successful manipulation, crises did not come to a head, and class struggles were not exacerbated. More conservative scholars embraced neo-corporatism as a solution to what was termed the 'problem of ungovernability' (Schmitter 1981). Ungovernability in modern democracies was widely thought to be a consequence of the over-burdening of the system of communication. There was also said to be a weakening of legitimacy, from the point of view of the citizen. Schmitter pointed rather to the inadequate co-ordination of interests and of demands by state agencies.

Corporatism offered itself as an alternative to the syndicalist view that a multitude of uncoordinated and sharply antagonistic groups confronted one another. In countries where the ideas of a social contract is undeveloped—as in Italy—or where a kind of 'bargained corporatism' is beginning to crystallize—as in Britain (Crouch 1977)—the notion of corporatism has been rejected by the unions.

Where strategies of negotiation and conflict are in a more differentiated fashion, it is often apparent that the possibilities of neo-corporatism have been overestimated. Great strides have been made in spatial planning, health policies and to some extent in education (Cawson 1978); but where many economic interests are involved, it seems that pluralist market models are more effective in articulating interests. Where ideologically founded alternatives are in question, as in environmental policy, negotiated settlements and compromise proposals tend to meet with strong opposition.

Corporatism was a 'growth sector' in the 1980s. Hardly any book on decision making could do without the key notion of corporatism. By the end of the 1980s increasingly non-corporatist strategies for growth and economic stability were discovered, by students of comparative policy research, especially in Japan, Switzerland and the USA. Corporatism in retrospect was linked to a basic social-democratic consensus. It withered away with Keynesianism and the optimism that state agencies are able to steer the society via 'moral suasion'. The erosion of socialism in eastern Europe was explained in some countries, such as Poland and Hungary, as a corporatist strategy. But most communist countries collapsed. New paradigms of transition to democracy overshadowed partial explanations, such as corporatism.

Scepticism against the steering capacities of the political system spread in the paradigm shift of system's theories towards autopoietic and self-referential systems and contributed to the end of the corporatist debate. Other scholars—who were pioneers of corporatist theories in the early 1980s—turned to new variations of partial theories to explain new forms of co-operation between state and interest groups, such as the theory of private interest governments (Schmitter, Streeck). Others worked on a more general theory of 'generalized political exchange' (Pizzorno, Marin, Mayntz) which tried to overcome the theoretical shortcomings of corporatist theories which had remained too close to empirical fact-finding in order to explain the development of modern and post-modern societies.

corruption

In its most general sense, corruption means the perversion or abandonment of a standard. Hence it is common to speak of the corruption of language or of moral corruption. More narrowly, corruption refers to the abandonment of expected standards of behaviour by those in authority for the sake of unsanctioned personal advantage. In the business sphere, company directors are deemed corrupt if they sell their private property to the company at an inflated price, at the expense of the shareholders whose interests they are supposed to safeguard. Lawyers, architects and other professionals are similarly guilty of corruption if they take advantage of their clients to make undue personal gains.

Political corruption can be defined as the misuse of public office or authority for unsanctioned private gain. Three points about the definition should be noted. First, not all forms of misconduct or abuse of office constitute corruption. An official or a government minister who is merely incompetent or who betrays government secrets to a foreign power for ideological reasons is not generally considered corrupt. Second, legislators and public officials in most countries are entitled to salaries and other allowances. Corruption occurs only when they receive additional *unsanctioned* benefits, such as bribes. In practice, it is frequently hard to draw the line between authorized and unauthorized payments; in any case, this will change over time and will be drawn differently in different countries. A benefit regarded as a bribe in one country may be seen as normal and legitimate in another. Legal definitions of corrupt practices are only an imperfect guide because benefits forbidden by law are often sanctioned by social custom, and vice versa. The boundaries of accepted behaviour can be especially difficult to determine in countries affected by rapid political and social change. Third, *electoral corruption* needs to be defined differently from other forms. Whereas most political corruption involves the abuse of public office, electoral corruption is the abuse of the process by which public office is won.

Common forms of corruption are bribery, extortion (the unauthorized extraction of money by officials from members of the public) and misuse of official information. Bribery need not consist of a direct payment to a public official. 'Indirect bribery' may

take the form of a promise of a post-retirement job, the provision of reduced-price goods, or the channelling of business to legislators or to members of their family.

Corruption was a serious problem in biblical and classical times, and was found in most periods of history. Cases of judicial corruption were particularly frequent. By the 1960s, an influential school of 'revisionist' political scientists nevertheless presented an optimistic view about the decline of corruption in advanced western democracies (Heidenheimer 1970). Some of the revisionists maintained that corruption did not present as grave a problem as previous writers had suggested. In many newly independent nations, where corruption was supposedly rampant, the practices condemned by western observers as corrupt (for example, making payments to low-level officials for routine services) were accepted as normal by local standards. Moreover, some forms of corruption, far from damaging the process of social and economic development, could be positively beneficial. Bribery enabled entrepreneurs (including foreign companies) to cut through red tape, thereby promoting the economic advance of poor nations. Corruption was seen as a transitory phenomenon, which was likely to decline as economic and social progress was achieved. The general trend was to be seen, it was argued, in the history of Britain and the USA. In Britain, electoral corruption, the sale of titles and government jobs, and corruption relating to public contracts had been rife until the nineteenth century. The introduction of merit systems of appointment to the civil service, the successful battle against electoral corruption and a change in public attitudes towards the conduct of government had led to a dramatic decline in corruption—a decline which coincided with the nation's economic development. Similarly, in the USA, corruption had been rampant in the late nineteenth and early twentieth centuries, which had been a period of intense economic and social change. As suggested by Robert Merton, the corrupt urban party machines, such as the Democratic Party organization in New York City (Tammany Hall) had provided avenues for advancement for underpriviliged immigrant groups. After the Second World War, full employment, the advance of education, the decline of political patronage and the growth of public welfare benefits combined to eliminate the deprivation that had previously led to corruption. A new civic culture replaced the former loyalties to family and to ethnic group. According to a common view, the party machine and the corruption that had accompanied it withered away.

This interpretation has come under challenge. Corruption is neither so benign in underdeveloped countries, nor is it so rare in advanced ones as previously thought. It is unrealistic to suppose that advances in education or in techniques of public administration, the development of a 'public-regarding ethos' or economic development can lead to the virtual disappearance of corruption. The growth of governmental activity and regulation in the modern state increases the opportunities and the temptations for corruption. Improvements in education need not lead to the elimination of corruption but to its perpetuation in new, sophisticated forms.

Revelations since the 1970s have led scholars to give increased attention to the contemporary problems of corruption in advanced democracies and in communist countries. In the USA, the Watergate affair of 1972–4 led to a wave of investigations that resulted in hundreds of convictions for corruption, including that of Vice-President Spiro Agncw. Others convicted included the governors of Illinois, Maryland, Oklahoma and West Virginia. Rampant corruption was uncovered in a number of states including

Florida, New Jersey, Pennsylvania and Texas. In Britain, the conventional view about the virtual elimination of corruption was shattered by several major scandals in the 1970s. The far-reaching Poulson scandal, involving local government corruption in the north of England as well as Members of Parliament, erupted in 1972. Local government corruption was proved in South Wales, Birmingham and in Scotland, while in London several police officers were imprisoned.

Since the 1980s, corruption has re-emerged as one of the most contentious and damaging issues in a number of countries. In the western democracies, some of the most serious scandals have involved large-scale, illegal funds to politicians for use in election campaigns. From 1981, all the major parties in the former West Germany were shaken by the Flick affair. Even more far-reaching have been the consequences of revelations that have led to the overthrow of the ruling Liberals in Japan and of the Christian Democrats in Italy.

The destabilizing effects of allegations of top-level corruption were also seen in the former Soviet Union, where the attack on graft was a central feature of Gorbachev's policy of perestroika and, in particular, of his criticism of the Brezhnev regime. The downfall of communist systems since the late 1980s has, however, merely led to the replacement of an old style of corruption by a new one. Mafia-type activities and corruption relating to privatization have emerged as barriers to the consolidation of stable democracies in these countries.

The 1990s have also seen the emergence of corruption as an issue of concern to western governments and to international organizations in their policies relating to aid to the Third World. Organizations ranging from the World Bank to the Organization for Economic Co-operation and Development have taken the view—in contrast to the revionism mentioned earlier—that corruption has severely damaged the prospects for economic growth, especially in Africa and Latin America.

The definitions, causes and effects of corruption and techniques of reform continue to be matters of controversy among sociologists and political scientists. What is increasingly accepted in the 1990s is that political corruption is a widespread, pervasive and serious phenomenon.

cost-benefit analysis

In terms of its practical application, cost-benefit analysis (CBA) is usually regarded as having its origins in the US Flood Control Act 1936. Without reference to the body of welfare economics that had already arisen by then, and before the introduction of compensation criteria into the literature, the Act argued that flood control projects had their social justification in a weighing up of the costs and benefits, with the latter being summed regardless of to whom they accrued. It is this reference to the *social* dimension of investment appraisal that distinguishes CBA from the more orthodox techniques which deal with the cash flow to a firm or single agency.

Oddly, CBA grew in advance of the theoretical foundations obtained from welfare economics that subsequently provided its underpinning. The notion that the benefits to individuals should be measured according to some indicator of consumer's surplus was well established by nineteenth-century writers, especially Dupuit and Marshall, but Hicks's work (1943) established the exact requirements for such measures. Similarly, the notion of a *shadow price* is crucial to CBA as, even if a project's output is marketed, CBA does not necessarily use market prices as indicators of value. Rather, reference is made to the marginal cost of providing the extra output in question. Despite the ambiguous relationship between marginal cost pricing in an economy where some sectors have unregulated pricing policies which force price above marginal cost, CBA and shadow pricing have flourished as an appraisal technique. CBA secured widespread adoption in US public agencies in the 1950s and 1960s, and was both used and advocated in Europe in the 1960s. It suffered a mild demise in the early 1970s in light of critiques based on the alleged fallacy of applying monetary values to intangible items such as peace and quiet, clean air and the general quality of life. Significantly, post-197 3 recession revived its use as governments sought value for money in public expenditure. Unease with the monetization of many unmarketed costs and benefits remained, however, resulting in a proliferation of alternative techniques such as environmental impact assessment, cost-effectiveness analysis (in which only resource costs are expressed in money and benefits remain in non-monetary units), and some multi-objective approaches. CBA retains its strength because of its ability potentially to identify optimal expenditures (where net benefits are maximized) and to secure a well-defined project ranking. However, few practitioners would argue that it has a role outside the ranking of expenditures within a given budget. That is, it has a highly limited role in comparing the efficiency of expenditures across major budget areas such as defence, education, health and so on.

As generally formulated, CBA operates with the efficiency objectives of welfare

economics. The maximization of net social benefits is formally equivalent to securing the largest net welfare gain as defined by the Kaldor-Hicks compensation principle. Academic debate in this respect has centred on the appropriate choice of the measure of consumer's surplus, with the dominant advocacy being of the use of the 'compensating variation' measure introduced by Hicks (1943). Use of social prices based on consumer valuations implicitly assumes that the distribution of market power within the relevant economy is itself optimal. As this is a value judgement, it is open to anyone to substitute it with an alternative distributional judgement. Some would argue that this apparent arbitrariness defines the inadequacies of CBA, while others suggest that no society has ever operated with disregard for distributional criteria and that distributional judgements are no less arbitrary than efficiency judgements.

Much of the practical effort in CBA has gone into actual mechanisms for discovering individuals' preferences in contexts where there is no explicit market. The most successful have been the hedonic price techniques and the use of bidding techniques ('contingent valuation'). Hedonic prices refer to the coefficients defining the relationship between property prices and changes in some unmarketed variable affecting property prices. An example would be clean air, which should raise the price of a property, other things being equal. Bidding techniques involve the use of questionnaires which ask directly for consumers' valuations of the benefits.

As costs and benefits accrue over time, CBA tends to adopt a discounting approach whereby future cash and non-cash flows are discounted back to a present value by use of a discount rate. The determination of the discount rate has occupied a substantial literature. In theory, one would expect consumers to prefer the present to the future because of impatience ('myopia') and expectations of higher incomes in the future (thus lowering their marginal valuation of a unit of benefit in the future). In turn, the resulting rate of time preference should be equal to interest rates ruling in the market which also reflect the productivity of capital. In practice, time preference rates and cost of capital estimates can vary significantly because of imperfections in capital markets. Moreover, the rate of discount relevant to *social* decisions can differ from the average of individual valuations, because choices made as members of society will differ when compared to choices made on an individualist basis. Further controversy surrounds the issue of intergenerational fairness since positive discount rates have the potential for shifting cost burdens forward to future generations. Thus the risks of, say, storing nuclear waste appear small when discounted back to the present and expressed as a present value. Conversely, zero discount rates may discriminate against projects which offer the highest potential for leaving accumulated capital for the use of future generations. To pursue the nuclear power example, non-investment because of the waste disposal problem could reduce the inherited stock of energy availability to future generations, by forcing a rapid depletion of finite stock resources such as coal or oil. The intergenerational issue is thus complex and raises the fundamental issue of just how far into the future CBA should look. Because of its foundations in consumer sovereignty, there is a temptation to argue that the time-horizon is set by the existing generation and, at most, the succeeding one or two generations.

CBA has enjoyed a revival of interest in recent years. Not only has there been a return of concern over the social value of public expenditure, but also the alternative techniques

developed in the 1970s have been shown to be even more limited in their ability to discriminate between good and bad investments. In particular, CBA has resurfaced through *environmental economics,* particularly with reference to the economic valuation of environmental costs and benefits. As an aid to rational thinking its credentials are higher than any of the alternatives so far advanced. That it cannot substitute for political decisions is not in question, but social science has a duty to inform public choice, and it is in this respect that CBA has its role to play.

counselling psychology

Counselling psychology is an applied psychological discipline concerned with generating, applying and disseminating knowledge on the remediation and prevention of disturbed human functioning in a variety of settings (Brown and Lent 1992). It has been a recognized discipline in the USA since 1947, and it is also well established in Australia and Canada, but it is really only since 1982, when the Counselling Psychology Section of the British Psychological Society was formed, that it became so established in Britain.

Counselling is essentially a psychological process. Its theories are concerned with helping individuals to understand and change their feelings, thoughts and behaviour. Counselling psychology, however, goes beyond this and provides a broader base. It is

a speciality in the field of psychology whose practitioners help people improve their well-being, alleviate their distress, resolve their crises, and increase their ability to solve problems and make decisions. Counselling psychologists utilise scientific approaches in their development of solutions to the variety of human problems resulting from interactions of intrapersonal, interpersonal, and environmental forces. Counselling psychologists conduct research, apply interventions, and evaluate services in order to stimulate personal and group development, and prevent and remedy developmental, educational, emotional health, organisational, social and/or vocational problems and adheres to strict standards and ethics.

(American Psychological Association 1985)

This definition can be broken down to reveal the most commonly identified tasks in the work of the counselling psychologist, namely collecting data about clients (assessment), personal adjustment counselling, specific problem identification and diagnosis, vocational counselling and long-term psychotherapy. Nelson-Jones (1982) stresses the importance of assessment, if the counselling psychologist is to be able to offer appropriate interventions beyond the fundamental counselling relationship. Given that counselling psychologists work one-to-one and with groups, in a variety of contexts such as industry, commerce, education, medical settings (in particular primary health care), community work and the private sector, it is evident that they intervene in a range of related areas and need to call upon a wide range of psychological knowledge. The recognition and awareness of the existence of post-traumatic stress, for example, demonstrated the need to develop specific and focused psychological counselling intervention.

Importantly, the helping relationship itself is seen as a crucial therapeutic variable, in that *counselling* psychology involves more than just the application of specific psychological treatment techniques in a standardized fashion (Woolfe 1990). Effective helping, whatever the theoretical model being used, is seen by counselling psychologists as a transactional encounter between people in order to explore their objective *and* subjective experience, which is best served when the relationship is characterized by the manifestation of personal qualities such as empathy, non-possesive warmth and authenticity on the part of the helper (Rogers 1951). That the self of the helper is an active ingredient in this process means that personal development work and the experience of being a client are mandatory ingredients in the training of counselling psychologists if they are to be able to monitor the process between themselves and the clients, and here lies the distinctiveness of counselling psychology with its emphasis on the issue of process as well as content and technique.

As well as an emphasis on the nature of the relationship between client and helper, counselling psychology generally emphasizes the distinction between well-being and sickness, and concerns itself with enhancing the psychological functioning and well-being of individuals. This is underlined by adopting a more holistic view of clients in that their mental health is considered in the location of an individual in the life cycle, in their lifestyle and relationships and in their social and political context, including the influence of gender (Taylor 1994). One of the strengths of counselling psychology lies in this humanistic way of looking at personal change and development grounded in a modern

sociological imagination. Furthermore, when employed in organizational structures, counselling psychologists are in a position to provide feedback about how those structures affect the quality of life of individuals within the organization and so play a part in facilitating constructive organizational change and good management practice.

Thus counselling psychology is a field notable for its diversity, influenced by diverse political and social forces as well as developments within mainstream psychology. Counselling psychology has overlaps with other areas of psychology, particularly with clinical psychology, However, a useful distinguishing factor is the issue of intentionality and the way counselling psychologists think about what they do. To quote Woolfe (1990):

> 'Counselling psychology brings a humanistic perspective to looking at human problems in that it perceives them not so much as deficits but as adaptations. In this sense it can be said to involve a paradigmatic shift from traditional psychological ways of looking at problems.'

creativity

Creativity is the ability to bring something new into existence. It shows itself in the acts of people. Through the creative process taking place in a person or group of persons, creative products are born. Such products may be quite diverse: mechanical inventions, new chemical processes, new solutions or new statements of problems in mathematics and science; the composition of a piece of music, or a poem, story or novel; the making of new forms in painting, sculpture or photography; the forming of a new religion or philosophical system; an innovation in law, a general change in manners, a fresh way of thinking about and solving social problems; new medical agents and techniques; even

new ways of persuasion and of controlling the minds of others.

Implicit in this diversity is a common core of characteristics that mark creative products, processes and persons. Creative products are distinguished by their originality, their aptness, their validity, their usefulness, and very often by a subtle additional property which we may call aesthetic fit. For such products we use words such as fresh, novel, ingenious, clever, unusual, divergent. The ingredients of the creative process are related functionally to the creative forms produced: seeing things in a new way, making connections, taking risks, being alerted to chance and to the opportunities present by contradictions and complexities, recognizing familiar patterns in the unfamiliar so that new patterns may be formed by transforming old ones, being alert to the contingencies which may arise from such transformations. In creative people, regardless of their age, sex, ethnic background, nationality or way of life, we find certain traits recurring: an ability to think metaphorically or analogically as well as logically, independence of judgement (sometimes manifesting itself as unconventionality, rebellion, revolutionary thinking and acting), a rejection of an insufficient simplicity (or a tendency to premature closure) in favour of a search for a more complex and satisfying new order or synthesis. A certain *naïveté* or innocence of vision must be combined with stringent requirements set by judgement and experience. The act of verification is a final stage in the creative process, preceded by immersion in the problem, incubation of the process subliminally, and illumination or new vision.

The birth of 'creativity'

The creative aspects of Mind and of Will engaged the attention of all the major philosopher-psychologists of the late nineteenth and early twentieth centuries. Alfred Binet, the famed constructor of intelligence tests, was known first through the pages of *L'Anneé Psychologique* in the 1880s and 1890s as the author of widely ranging empirical studies of creativity (including research by questionnaire and interview of leading French writers) and the originator of dozens of tests of imagination (devised first as games to play with his own children). The fateful decision to exclude such occasions for imaginative play from his compendium of tasks prototypical of needed scholastic aptitudes has led to much mischief in educational application and to continuing confusion about the relationship of intelligence to creativity. The former as generally measured is important to certain aspects of the latter, but people of equal intelligence have been found to vary widely in creativity; and, alas, some notably creative persons have also been found notably lacking in whatever it takes to get on successfully in school.

Of the two most famous psychoanalysts, Carl Jung made a greater contribution than Freud in this field, developing especially the notions of intuition and of the collective unconscious as the sources of creation. Henri Bergson (1911 [1907]), in *Creative Evolution,* distinguished intuition from intellect as the main vehicle of the creative process in mind-in-general and in what, in retrospect, is more than mere vitalism he attributed to will, as *élan vital,* the chief motivating force of the creative process in nature. Nearly a century after Bergson's initial formulations, Gregory Bateson (1979) was writing in that same tradition, and his gradual development of 'an ecology of mind'

found expression in his *Mind and Nature: A Necessary Unity.*

The modern empirical study of creativity

New methods of observation and measurement have produced a marked proliferation of articles and books about creative persons, processes and products since the Second World War. A commonly recognized milestone in the systematic research effort is an address in 1950 by J.P.Guilford who, as president of the American Psychological Association, pointed out that up to that time only 186 out of 121,000 entries in *Psychological Abstracts* dealt with creative imagination. In the following decades there was a surge of publications in the field. Studies at the University of California of highly creative contemporary writers, architects, artists, mathematicians and scientists by intensive methods of personal assessment contributed important impetus to the study of personality and creativity (work funded mostly by foundations such as Carnegie, Ford, Rockefeller, and Richardson), while the US Office of Education gave significant support to research on creativity in education. A bibliography published in the late 1960s by the Creative Education Foundation contains 4,176 references, nearly 3,000 of them dated later than 1960.

Yet this abundance of effort also produced a mixed picture of results based on psychological measurement, due mainly to inconsistencies in the choice of measures, their relative unreliability, and the equally inconsistent, somewhat unreliable, and factorially and definitionally complex criteria. Psychologists generally have restricted the term creativity to the production of humanly *valuable* novelty in an effort to exclude from consideration the relatively mundane expressions of creativity in everyday life, but this introduction of value to the definition of creativity, and the consequent invocation of historically bound and subjective judgements to assess such value, necessarily raise theoretical and methodological questions which have bedevilled and divided students of creativity for decades. *Whose* values, for example, must be met for an act to be creative— the values of the creative agent alone, or the values of a social group? And if so, which group?

Further, should the term creative be restricted to novel activities valued by connoisseurs of achievement in the classically 'creative domains' of literature, music and other arts, or can it be applied also to novel behaviour valued by those able to recognize achievement in mathematics, science and technology? While most creativity scholars and investigators extend 'creative' to these latter domains with few qualms, they do not generally assume that the creative processes involved in producing good literature, good music, good art and good science are the same, or that the personality and intellectual characteristics associated with creative achievement in these various domains are highly similar. Whether the term creative can be extended to novel activities of value in domains such as business, sports, teaching, therapy, parenting and homemaking is an even more controversial question among creativity scholars.

Nor can the issue of values and standards be resolved simply by accepting as legitimate a particular domain of activity, for even within a specific domain, such as art, the question remains: whose values or standards are to be met—the values and standards of

the artist who produced the piece, of other artists, of art critics, of art historians, or the audience in general? And if other artists, *which* artists; if art critics, *which* art critics; and if art historians, *which* art historians—from which schools and what eras? If behaviour in less public domains (for example, therapy and parenting) is considered, who is to assess the novelty and effectiveness of the behaviour and how is scholarship and investigation to proceed?

Intimately related to the question of values and standards are questions concerning the nature or form of the act's impact. Several theorists, for example, have drawn distinctions between acts of 'primary' creativity—acts whose values derive from their power to transform in a basic way our perception of reality or our understanding of the universe of human experience and possibility—and acts of 'secondary' creativity—acts which merely apply or extend some previously developed meaning, principle or technique to a new domain or instance.

While it would be comforting to be able to report that the definitional differences and distinctions reviewed here are relatively trivial compared to the core of common meaning contained within them, it is not at all clear that this is so. Whether creative individuals are identified on the basis of their achievements, or their skills and abilities, or their activities, or their personality characteristics, shapes answers to frequently asked substantive questions about creativity. (For example, can creativity be taught or fostered? Can creativity be predicted? How are creativity and intelligence related?) Definitional differences and variations in emphasis have led, and will continue to lead, to many misunderstandings, misreadings and confusions in the study of creativity. Readers of the psychological literature on creativity are therefore well advised to ascertain the conceptual perspectives and operational definitions of the scholars and investigators whose works they are examining. Thus, not only measurement unreliability in both predictors and criteria but also basic definitional questions as well as the genuine role of chance itself in both the genesis and the recognition of creativity have served to confound results. Overall, none the less, a strong impressionistic consensus of the sort reported at the outset of this article prevails; the research enterprise continues undeterred.

A critical review of the professional literature on creativity in the decade 1970–80 (Barron and Harrington 1981) turned up approximately 2,500 studies, produced at a steady rate of about 250 per year during that decade. The literature has grown since. Emerging new themes in the 1980s and early 1990s include creativity in women, computer-assisted creativity and creativity in the moral domain. There is renewed interest in the apparent relationships between bipolar affective disorders and creativity, the development and developmental significance of creativity over the lifespan, and a heightened consciousness that creativity is deeply embedded in social, historical, economic and cultural circumstances. This awareness has led to the development of 'ecological' or 'systems' perspectives that attempt to integrate what is known about creative people, creative processes, and creative social contexts and to connect the intrapsychic, interpersonal, social and cultural properties of creativity in theoretically useful ways. Such broadened theoretical efforts have led naturally to calls for more vigorous multidisciplinary approaches to the study and understanding of creativity.

credit

The term credit, derived from the Latin *credere* (to believe), has several meanings, many of which are outside the field of finances. Even in finance it can be used to indicate a positive accounting entry, an increase in wealth or income, but the main use, with which we are concerned here, involves an element of deferred payment. It thus covers not only formal loans but also the multitude of informal arrangements whereby payment for a transaction is made some time after the physical transfer of the goods or services, and by extension it is also used where payment is made in advance. In accounting terms it refers not only to trade credit between businesses but also to the various items known as accruals. Examples of such accruals are the payment of salaries after a person has worked for a week or a month and, on the other side, the advance payment of a year's premium for insurance.

In macroeconomics the term is used with a special meaning to refer to those items of credit that are measurable for the economy as a whole; in practice this restricts it to credit

extended by the banking system. As bank loans are made, the proceeds are used to pay for goods and services, and the recipients of these payments pass the cheques to the credit of their own bank deposits: bank loans can be said to create bank deposits. By controlling the volume of bank credit, the monetary authorities can thus indirectly control the volume of bank deposits, which are the most important element in the money supply. The control of bank credit, both in total volume and in the selection of favoured and unfavoured borrowing sectors, is thus often a weapon of monetary policy.

Credit plays an important part in the theory of financial intermediation. The first stage of development of a financial system can be taken as the move from barter to the use of commodity money. Although this move frees the exchange of commodities from the restrictions of barter, by itself it does nothing for the growth of business enterprises because the only funds available for capital investment come from the current income or the previously accumulated money balances of the entrepreneur. The development of credit, in the form of direct lending and borrowing, enables the accumulated money balances of others to be transferred to the entrepreneur, who can thus put to profitable use the savings of many other people. Because this development was associated with the levying of interest, it faced religious and social obstacles; these still persist in Muslim countries, where an alternative form of banking (Islamic banking) has been developed on the basis of profit-sharing by the depositor.

For several centuries, credit, both as formal loans and as trade credit, was restricted to businesses and the wealthier households, but since the mid-1930s all but the poorest households have obtained access to formal and informal credit. This extension of credit has been achieved by a number of innovations in the forms in which credit is granted. Few of these forms were completely new; the innovations came in the use to which they were put and in the ways in which they were combined.

All lenders need to satisfy themselves on two points before granting credit: these are the ability of the borrower to repay and his willingness to do so. Traditionally, the ability to repay was assured by requiring the borrower to give the lender a mortgage or charge on assets to a value greater than that of the loan, and willingness to repay was assessed on the past record of the borrower and personal knowledge of his character. Unless the loan is for the purchase of a house, the problem raised in giving credit to the ordinary household is that there are no suitable assets to pledge as security. The solution has taken several forms. The first was to obtain a mortgage on the asset (car or television set, for example) that was being purchased with the loan; where the legal system did not permit this (as under English law), the asset was hired to the 'borrower', with a final nominal payment to transfer ownership—hire purchase. Even where this legal subterfuge was not necessary, there was a growth in leasing and straight hiring to households to overcome many of the credit problems.

The key change in this form of consumer lending was a realization that current income rather than accumulated assets was the real security for a loan. In lending on consumer durables, this came about because there is a poor secondhand market, but even with houses lenders prefer to avoid the trouble of auctioning the property to secure repayment. During the 1960s this change of attitude towards the nature of the security for a loan was also adopted in corporate lending; it came to be known as lending on the cash flow. For large corporate loans, banks often use their computers for simulating the cash flows of

prospective borrowers under a number of hypothetical conditions.

It is obvious from the previous analysis that the key point in granting credit is the assessment of the creditworthiness of the borrower. In the past much of this depended on the personal judgement of local bank managers and on adequate collateral. With the growth in the number of customers, branch managers cannot now claim a close knowledge of all their customers, and more formal methods of assessment have become necessary. This is particularly necessary when loans can be obtained by post through the filling in of a simple questionnaire or even through answering questions posed by an electronic terminal. Most of the methods used are based on credit scoring, which uses a statistical technique known as multivariate discriminant analysis (MDA) or one of its variants. Applicants are scored according to such characteristics as ownership of their home, steady employment, and possession of a telephone, and the loan is granted if the score exceeds a predetermined level based on past experience of bad debts.

The experience of the 1980s and early 1990s brought to the fore several new aspects of assessing creditworthiness. During the 1970s banks throughout the world had vied to take part in syndicated lending to developing countries on the assumption that loans to governments were relatively risk-free. The international debt crisis starting in 1982 showed this belief to be wide of the mark, and banks began to develop schemes for taking into account the risks involved in worldwide movements of commodity prices—country or sovereign risk. The huge provisions that banks had to make against these international loans were more than matched during the recession of the early 1990s by defaults on domestic loans of all sorts, from corporate loans to consumer debt and mortgage loans. It would be nice to think that banks had learned the lesson that the most creditworthy of borrowers is vulnerable when economic circumstances change enough and to allow for this possibility in their risk assessments, but experience shows that banks nearly always begin to lend carelessly in periods of strong competition.

crime and delinquency

In everyday language crime and delinquency are terms that carry substantial emotional

content. One hears people speak of all sorts of unseemly behaviour as being 'criminal' or the finger pointed at unruly children as 'delinquents'. In this usage, the terms carry considerable cultural baggage which for the scientific study of crime and delinquency not only is excess, but also makes systematic study impossible. No reasonable generalizations could be made about the actors or acts to which some people would normally apply the terms. For this reason, scholars have attempted to conceptualize crime and delinquency in a more restricted fashion in order to give more precise meaning to the terms. Although there is not consensus on the matter, the prevailing view among triminologists is that crime should be restricted to those acts which are defined as violations of the criminal law. Even this more restricted definition, however, is troublesome when general theories of crime are sought because it encompasses so much: government officials who plan and carry out criminal acts (conspiracies to commit political assassinations such as the numerous US intelligence agencies plots to assassinate Fidel Castro), corporate executives who violate health and safety laws or engage in illegal economic transactions, juveniles who are truant from school or who hang about in gangs, acts of physical abuse of spouses and children, murder, rape, theft and robbery.

Despite the conceptual problems that inhere in the acceptance of the legal definition of crime and delinquency there are advantages as well. For one, the legal definition provides an objective criterion for what is included in the study of crime and delinquency. To determine whether or not an act is a crime one need only look to see if a law has been passed which provides for punishment by state officials. Another analytical advantage of limiting crime and delinquency to the legal definition is that it allows for cross-cultural comparisons which reveal that some acts are defined as criminal in all state societies and, equally important, that what is crime in one nation-state or at one historical period is not crime in another country or at a different time. For example, murder, rape and theft are criminal in every state society, but acts of business executives or journalists that are a crime in one country are not in another. If the Secrecy Act of Great Britain were in force in the USA and US journalists exposed governmental crime as they presently do, US journalists would be well represented in the prison population. Heroin addicts can obtain drugs through state-monitored programmes in some countries and in others they face long prison sentences merely for possessing the drug. Marijuana may be purchased in cafés in The Netherlands but possession of small amounts can land a person in prison for many years in others. Even within a country different jurisdictions define criminality differently: in the USA marijuana possession is a felony for which a conviction can earn a defendant forty years in prison in one state but in an adjoining state it is a misdemeanour punishable by a very small fine or it is not criminal at all. Even acts which we accept today as 'clearly criminal' such as murder and rape once were viewed as wrongs which should be settled in accordance with the wishes of the aggrieved party or the party's relatives rather than acts which the state should punish. In many countries local courts still operate on this principle. In the USA American Indian communities emphasize the importance of providing transgressors a right of passage back into legitimate roles, and in many Mexican and African villages there is a similar emphasis as well. The anthropologist Laura Nader (1990), in her cross-cultural studies of law and crime, found that stateless societies and small communities are much more likely to invoke the principle of 'give a little, get a little', rather than 'winner take all' when

members of the community deviate from accepted norms.

The definition of crime and variations in what constitutes crime in time and space is, of course, only the beginning of the systematic study of crime and delinquency by social scientists. The heart of the discipline is determined by what questions are asked in the effort to understand. The study of crime and delinquency is as diverse as are the social sciences, but three sets of questions have dominated the field.

First, the question most often asked in the field is 'Why do some people commit crime and others do not?' From the first studies of crime and delinquency in Italy, England and France the search for an adequate answer to this question has led researchers to seek biological, sociological, psychological, economic and even geographical variables associated with and presumably causally related to criminal and delinquent behaviour. That this quest has been somewhat less than successful is not surprising when it is realized that practically everyone commits some types of crimes in the course of a lifetime. The search for an answer to why some people commit crime, then, is nothing less than a search for a theory of human action. It is probably safe to say that the cross-fertilization of general social psychological theories of human action and social psychological theories of criminal and delinquent behaviour is to date the most valuable contribution made by this orientation.

Second, social science research on crime and delinquency also has asked the sociological (as contrasted with social psychological) question, 'Why do rates and types of crimes and delinquency vary from one society or group to another?' The answers to this question are as diverse and contradictory as are those of the social psychologists. As with sociology generally, the answers offered invariably invoke some combination of cultural and subcultural values with economic and social position in a given society. The different theories that try to answer the question can be divided between the relative importance attributed to these different sociological forces.

Third, since the mid-1980s there has been rapid growth in efforts to answer two other fundamental questions about crime and delinquency: 'What are the social forces that lead to the definition of some acts as criminal and not others?' and 'How does the criminal justice system of police, prosecutors, courts and prisons work and what effect does it have on the perception, reporting and incidence of crime and delinquency?' These questions dovetail the study of crime and delinquency with the sociology of law and they have provided for a great deal of valuable cross-fertilization between the fields. As might be expected, the theories put forth to answer this question are dominated by the theoretical traditions of Durkheim, Marx and Weber, and equally predictably there has not emerged a consensus among scholars as to which paradigm best answers the question.

There is no reason to suppose that the future of studies of crime and delinquency will veer very far away from these basic questions. In view of the salience of crime as a political and economic issue, however, it is likely that rather more resources will be devoted to questions about the appropriateness of defining acts as criminal and the functioning of the criminal justice system. The issue of whether using drugs should be criminalized is preoccupying most western countries, and the growth and power of what the Norwegian criminologist Nils Christie (1993) calls 'the crime industry' is deservedly receiving a great deal more attention than heretofore. Regardless of these changes, it is safe to say that the search for answers to and the gathering of empirical data on all three

questions will occupy the social-scientific study of crime and delinquency for the future as it has for the past two hundred or more years.

criminology

Standard textbook accounts find two scriptural beginnings to the history of criminology: the 'classical school' and the 'positivist school', each one marking out a somewhat different fate for the discipline. More sophisticated criminologists have rewritten this history (Beirne 1993; Garland 1985; 1994) but the conflict between these two trajectories still remains a useful way of understanding the shape of a discipline conventionally defined as 'the scientific study of crime and its control'.

The classical trajectory dates from the mid-eighteenth century and tells of the revolutionary contribution of Enlightenment thinkers like Beccaria and Bentham in breaking with a previously 'archaic', 'barbaric', 'repressive' or 'arbitrary' system of criminal law. For these reformers, legal philosophers and political theorists, the crime question was predominantly the punishment question. Their programme was to prevent punishment from being, in Beccaria's words, 'an act of violence of one or many against a private citizen'; instead it should be 'essentially public, prompt, necessary, the least possible in given circumstances, proportionate to the crime, dictated by laws'.

Classicism presented a model of rationality: on the one side, the 'free' sovereign individual acting according to the dictates of reason and self interest; on the other hand, the limited liberal state, contracted to grant rights and liberties, to prescribe duties and to impose the fair and just punishment that must result from the knowing infraction of the

legal code and the knowing infliction of social harm.

This 'immaculate conception' of the birth of the classical school as a humanistic reform has been challenged by revisionist histories of law and the state. Dates, concepts and subjects have been reordered. Classicism is now more likely to be conceived in terms of the broader rationalization of crime control associated with the emergence of the free market and the new capitalist order. But whatever their origins, the internal preoccupations of classicism—whether they appear in utilitarianism, Kantianism, liberalism, anarchism or indeed any political philosophy at all—have never really disappeared from the criminological agenda. This is where the subject overlaps with politics, jurisprudence and the sociology of law.

A century after classicism, though, criminology was to claim for itself its 'real' scientific beginning and a quite different set of influences. This was the positivist 'revolution', dated in comic-book intellectual history with the publication in 1876 of Lombroso's *Delinquent Man.* This was a positivism which shared the more general social-scientific connotations of the term (the notion, that is, of the unity of the scientific method) but which acquired a more specific meaning in criminology. As David Matza (1964; 1969) suggests in his influential sociologies of criminological knowledge, criminological positivism managed the astonishing feat of separating the study of crime from the contemplation of the state. Classicism was dismissed as metaphysical speculation. The new programme was to focus not on crime (the act) but on the criminal (the actor); it was to assume not rationality, choice and free will, but determinism (biological, psychic or social). At the centre of the new criminological enterprise was the notion of causality. No longer sovereign beings, subject to the same pulls and pushes at their fellow citizens, criminals were now special creatures or members of a special class.

The whole of the last century of criminology can be understood as a series of creative yet eventually repetitive variations on these late nineteenth-century themes. The particular image conjured up by Lombroso's criminal type—the atavistic genetic throwback—faded away, but the subsequent structure and logic of criminological explanation remained largely within the positivist paradigm. Whether the level of explanation was biological, psychological, sociological or a combination of these ('multifactorial' as some versions were dignified), the Holy Grail was a general causal theory: why do people commit crime? This quest gave the subject its self-definition: 'the scientific study of the causes of crime'.

At each stage of this search, criminology strengthened its claim to exist as an autonomous, multidisciplinary study. Somewhat like a parasite, criminology attached itself to its host disciplines (law, psychology and, dominantly, sociology) and drew from them methods, theories and academic credibility. At the same time—somewhat like a colonial power landing on new territory—each of these disciplines descended on the eternally fascinating subjects of crime and punishment and claimed them as their own. In this fashion, the theories, methods and substance of criminology draw on Freudianism, behaviourism, virtually every stream of sociology (the Chicago School, functionalism, anomie theory, interactionism, etc.), Marxism, feminism, rational choice theory and even post-modernism. Each of these traces can be found in any current criminological textbook; it would be difficult to think of a major system of thought in the social sciences which would not be so represented.

All the time, however, that this positivist trajectory was being established, criminologists retained their interest in questions of punishment and control. If, in one sense, all criminology became positivist, then also all criminology has always been concerned with classical matters. But instead of thinking about the limits and nature of the criminal sanction, this side of criminology (sometimes called penology) took this sanction as politically given. True, there was (and still is) an important debate about whether the discipline's subject matter should be confined to conventional legal definitions of crime or broadened to include all forms of socially injurious conduct. And the criminalization versus decriminalization debate is still very much alive, in areas such as corporate wrong-doing, pornography and drug abuse.

Questions of punishment and social control, however, became part of a more scientific discourse: the construction of empirical knowledge about the workings of the criminal justice system. Research findings were built up about the police, courts, prisons and various other agencies devoted to the prevention, control, deterrence or treatment of adult crime and juvenile delinquency. The structure and ideologies of these agencies are analysed, their working practices and relations to each other observed, their effectiveness evaluated. This is now a major part of the criminological enterprise.

Behind this work, the classical tradition remains alive in another sense. Modern criminologists became the heirs of the Enlightenment belief in rationality and progress. Their scientific task was informed by a sense of faith: that the business of crime control could be made not only more efficient, but also more humane. As reformers, advisers and consultants, most criminologists claim for themselves not merely an autonomous body of knowledge, but also the status of an applied science or even profession.

It is this simultaneous claim to knowledge and power that links the two sides of the criminological discourse: causation and control. In positivism, this is an organic link: to know the cause is to know the appropriate policy. But the history and status of this link is more complicated. The early nineteenth-century penitentiary system was dependent on theories of rehabilitation, behaviour modification and anomie well before their supposed 'discovery' by scientific criminology. There is a lively debate about Foucault's characterization of criminological knowledge as wholly utilitarian, an elaborate alibi to justify the exercise of power.

In the general climate of radical self-scrutiny which descended on the social sciences in the 1960s, criminology too began to fragment. There were three major attacks against what was visualized as the positivist hegemony. Each in its own peculiar and quite distinct way represented a revival of classicist concerns.

First, labelling theory—a loose body of ideas derived from symbolic interactionism—restated some simple sociological truths about the relativity of social rules and normative boundaries. Crime was only one form of that wider category of social action, deviance; criminology should be absorbed into the sociology of deviance. Beyond such conceptual and disciplinary boundary disputes, the whole quest for causality was regarded with scepticism. In addition to the standard behavioural question (why do some people do these bad things?) there were a series of definitional questions. Why are certain actions defined as rule-breaking? How are these rules applied? What are the consequences of this application? These definitional questions took causal primacy: it was not that deviance led to control, but control to deviance. Social control agencies—the most benevolent as

well as the most punitive—only made matters worse. Sympathy and tolerance for society's outsiders were preferable to the conformity and scientific pretensions of mainstream criminology.

Second, this liberal criticism became harder in the 1960s onslaught on mainstream criminology. This came from what was labelled variously as conflict, new, critical, radical or Marxist criminology. Combining some strands of labelling theory and conflict sociology with classical Marxist writing about law, class and the state, this critique moved even further from the agenda of positivism. Traditional causal inquiries, particularly individualistic, were either dismissed or subsumed under the criminogenic features of capitalism. Legalistic definitions were either expanded to include the 'crimes of the powerful' (those social harms which business and the state license themselves to commit) or subjected to historicist and materialist enquiry. Labelling theory's wider category of deviance was refocused on law: the power of the state to criminalize some actions rather than others. The analytical task was to construct a political economy of crime and its control. The normative task was to eliminate those systems of exploitation that cause crime.

The third critique of the positivist enterprise came from a quite different theoretical and political direction, one that would prove more enduring. Impressed by the apparent failure of the causal quest and of progressive policies such as treatment, rehabilitation and social reform ('nothing works' was the slogan), loose coalitions appeared in the 1970s under such rallying calls as 'realism', 'back to justice' and 'neo-classicism'. Some of this was neo-liberalism—sad disenchantment with the ideals and policies of progressive criminology. Some was neo-conservativism—satisfaction about the supposed progressive failures. But politics aside, all these criminologists began turning back to classical questions. The notion of justice allowed liberals to talk of rights, equity and fairness and to advance the Kantian-derived 'just-deserts' model of sentencing. In the face of massively escalating crime rates throughout the west, conservatives (and just about everyone else) talked about law and order, social defence, deterrence and the protection of society. The traditional positivist interest in causation seemed less important than devising rational crime control policies.

By the beginning of the 1990s, the fragmented discourse of criminology was settling into yet another pattern. The original labelling and radical moments all but disappeared, most of their cohort denouncing its own earlier romantic excesses in favour of what is called 'left-realist criminology'. This is more receptive to reformist social policy and more interested in victimization and causation. 'Victimology' has become a major subfield in itself. The mainstream non-positivist position has become highly influential in various forms of managerial or administrative criminology. These emphasize 'situational crime prevention' (designing physical and social space to reduce criminal opportunity) and rest on an image of the new 'reasoning criminal' (Cornish and Clarke 1986) derived from rational choice theory. At the same time, traditional positivist inquiry remains very much alive in the form of massive birth cohort or longitudinal studies about the development of criminal careers. A more theoretically innovative direction comes from Braithwaite's neo-Durkeimian theory of reintegrative shaming (Braithwaite 1989).

Most criminologists now work in what has been separated off in the USA as the applied field of criminal justice studies. Basic theoretical debates—whether about the

nature of the subject or the nature of criminality—are still alive but less prestigious. The subject remains ethnocentric: seldom engaging with the less developed world or with crimes of the state or with political violence.

The diversity in modern criminology arises from two tensions. First, crime is behaviour, but it is behaviour which the state is organized to punish. Second, crime raises matters of pragmatic public interest, but it has also created its own theoretical discourse.

critical legal studies

Critical legal studies is an intellectual and political movement accommodating a diversity of resistances to the orthodox study of law in doctrinal terms. Consistent with origins in the radical political culture of the 1960s, critical legal studies (CLS) has sought to effect libertarian reforms in legal education, but its success with this has been less conspicuous

than the large impact it has had on legal theory. CLS has specific institutional presences in various loose organizations and annual conferences in Europe and the USA. It can also claim a significant literature for itself.

CLS has thrived on opposition. Rarely can an intellectual endeavour so diverse and eclectic have caused such hostility within academic orthodoxy. CLS has been a persistent provocation to mainstream legal scholarship from its earliest guise as variants of phenomenology and critical social theory to its later inclusion of post-modernism, feminism and anti-racism. This conflict is in one way unsurprising. What has united the several strands of CLS has been a radical interrogation of the academic adequacy and the operative autonomy of doctrinal approaches to law. In another way the opposition to CLS does seem surprising because there are social perspectives on law, such as those provided by the sociology of law, which have long questioned the self-sufficiency of the legal domain. This questioning has, however, largely taken the integrity of law as given and then related law to various social influences or determinations. The dangerous dimension of CLS has consisted in its scrutiny of law from within, a scrutiny that has revealed basic division and contradiction within law itself, not only as an academic field but also as the very rule of law held necessary for the viability of liberal society. In particular, by looking closely at legal doctrine in operation, CLS has shaken law's claims to consistency, certainty and predictability.

The cunning of law, however, knows no bounds. The disorientation of law effected by CLS does raise the issue of why such a precarious entity as law endures. CLS has in ways added to law's mystery, and even its potency, by showing, at least obliquely, that law survives in the face of its own incoherence. Perhaps this is why CLS has come to explore the arcanum of law's distinct 'force' or its (paternal) authority by resort to deconstruction and psychoanalysis. Another influential response in CLS to law's radical uncertainty has been the discovery that there is an ineluctable place within law for ethics and justice—elements which were supposedly excluded in doctrinal claims to completeness. This marks something of a return to law, to finding sources of critique within law itself.

In all, the old enemy of doctrine persists and CLS continues to provide expansive protocols of combat which themselves would find coexistence difficult without this common adversary.

crowding out

The concept of the crowding out of private sector activity by expansions of government sector has become increasingly important in political/academic debates. All participants in the debate accept that if the economy is at full employment, an increase in government spending will reduce private sector spending. The debate is concentrated on the effect of increases in government spending away from full employment. If government spending rises by $100 million and national income increases by less than $100 million, then crowding out is said to have occurred. In other words, crowding out is associated with a *multiplier* of less than unity. Even if national income rises by more than $100 million, it would normally be the case that the higher interest rates associated with higher borrowing will reduce productive private sector investment and so 'crowd out' some elements of national income.

The resurgence of interest in crowding out has been associated with the monetarist critique of macroeconomic policy and has received its main theoretical (Carlson and Spencer 1975) and empirical (Anderson and Jordan 1968) support from work undertaken at the Federal Reserve Bank of St Louis in the USA. Although much of this work has been discredited (see Goldfeld and Blinder 1972), the political impact has been increasing. Apart from the interest rate effect on a number of other possible sources for crowding out have been suggested. Increased government expenditure may have a depressing effect on people's expectations about the future possible productivity of the economy, and so causing them to reduce investment. Alternatively, investment could be so interest sensitive that even a small rise in the interest rate will reduce investment fully in line with the increase in government spending (this is sometimes known as the Knight case, after the Chicago economist Frank Knight).

The major case emphasized by monetarist economists comes from an analysis of the financing of a government deficit. To have an impact on the economy a deficit has to be sustained for a number of years, but each year that deficit has to be financed by borrowing or printing money. Continual financing by borrowing will raise interest rates as the government competes for funds, and the gradual increase in interest rates will reduce investment. As well as this effect, it may be stressed that government debt is safer than private debt, so dollar for dollar substitution will increase the liquidity of the economy and reduce the impulsion to save (and therefore reduce investment funds).

However lacking in persuasiveness these arguments may be, there is strong empirical support for the proposition that multipliers are very low in the UK at least (Cook and Jackson 1979). In versions of the Treasury Model and the Keynesian National Institute model, long-run multipliers vary from 1.1 to 0.4 giving considerable credence to the arguments in favour of crowding out. This does not demonstrate that fiscal policy is impossible, but that it is just difficult to sustain.

cultural anthropology

Cultural anthropology is the study of the social practices, expressive forms, and language use through which meanings are constituted, invoked and often contested in human societies. The term cultural anthropology is generally associated with the American tradition of anthropological research and writing. In the early part of the twentieth century, Franz Boas (1940) was critical of the assumptions of evolutionary anthropology and of its racial implications; in developing his critique, he focused on the particularities of different ways of life rather than upon broad comparison and generalization, and on demonstrating that race and culture were not coterminous. Boasian anthropology, as George Stocking (1974:19) has suggested, elaborated a concept of culture as a 'relativistic, pluralistic, holistic, integrated, and historically conditioned framework for the study of the determination of human behavior', a concept that involved an emphasis on language as an embodiment of culturally significant classificatory systems.

The Boasian emphasis on culture as a particularized, patterned and shared set of categories and assumptions that often did not rise into conscious awareness directed anthropologists working in this tradition to focus upon the meanings rather than the functions of social and cultural practices, and upon the specificities of these meanings rather than upon the construction of cross-cultural sociological laws and principles.

This way of thinking about culture is a significant and enduring paradigm that

continues to inform American anthropology, and it was influential in the development of French structural anthropology as well. Edward Sapir, a student of Boas, adumbrated later critiques of some Boasian assumptions with his stress on individual creativity in culture and in language, and with his writings on the diversity of perspectives within societies (1949). Since at least the late 1970s cultural anthropologists, while retaining the emphasis on culture as a set of signs and meanings, have been further challenging some Boasian assumptions about culture as a shared, integrated and taken-for-granted unified whole; as a result, they are experimenting with a variety of novel interpretive and writing strategies.

Broadly speaking, these challenges have resulted from a rethinking of the idea of culture on four interrelated fronts: considerations of the politics of representing other cultures and societies; considerations of the power relations in which cultural meanings are always situated; reconsiderations of the relation of language to culture; and considerations of person, self and emotion in relation to cultural meanings. Together these frame a broad spectrum of research and writing in cultural anthropology.

The politics of representation

Edward Said's enormously influential argument in *Orientalism* (1978) was that western descriptions of other (usually formerly colonized) cultures typically represent them as static, mired in an unchanging and unchallengeable tradition, and as exercising such control over behaviour and attitudes that people are unable consciously to critique or transform their own societies or to exercise agency with respect to them. Said views this as a dehumanizing mode of writing that not only serves the political interests of the colonizing and formerly colonizing west, but also allows the west to define itself as advancing rather than static, and as scientific and rational rather than traditional. Cultural anthropologists have considered the implications of these and other critiques of western writing about other societies, and the way that older conceptions of culture reinforced such representations. As a result they have transformed their modes of writing and analysis to highlight the historically changing nature of all societies, the active construction and deployment of tradition in the cultures they study, and to reflect on the inevitably political nature of all anthropological writing and to make this explicit in their writing.

Culture and power

Boasian and structural definitions of culture typically involve assumptions about the degree to which culture is shared within a given community, and the degree to which cultural propositions are part of everyday taken-for-granted and unquestioned common sense. Cultural anthropology, often drawing upon the work of Pierre Bourdieu (1977), has come to emphasize instead the tactical uses of cultural discourses in everyday social practice, and influenced as well by the writings of Michel Foucault (1977; 1978), the ways that cultural propositions are upheld by and serve the interests of certain segments

of a society. Feminist anthropology and research on the politics of class and race have been of critical importance in this move to interpret culture as an arena characterized as much by struggle and contestation as by consensus. Thus, for example, many feminist anthropologists have turned their attention to the poetics and politics of ritual, story, song and other expressive traditions that offer implicit or explicit critiques of authoritative cultural discourses concerning gender, kinship, and economic and political institutions. Ethnographic writing has come to focus upon the relationship of culture to power and, reflecting upon the work of James C. Scott (1985; 1990) and others on the nature of resistance, to emphasize the fact that cultural discourses may be challenged, contested or negotiated by those whom they disadvantage. Cultural anthropologists have also analysed the deployment of cultural traditions as responses to power relations on a global scale, to specific colonial and postcolonial political and economic situations, belying earlier assumptions about the fixity and timelessness of 'tradition'.

Language in cultural anthropology

The shift in anthropology from a definition of culture stressing stasis, internal consistency and homogeneity to one stressing heterogeneous meanings deployed for different persuasive purposes is paralleled and in some ways foreshadowed by the shift away from the Boasian and structuralist concern with language as a formal system of abstract cultural categories to a concern with the linguistic strategies through which speakers rhetorically construct and reconstruct status, identity and social relationships in varied situations of everyday life. Speech, these anthropologists argue, is always produced in specific historical and micropolitical contexts, and it both reflects and is constitutive of the power relationships implicit in the speech situation. Cultural anthropologists frequently use the term *discourse* to characterize language envisioned as a set of resources that speakers draw upon to construct and negotiate their social worlds in specific contexts. The word is intended to evoke the idea of language and culture as implicated in a universe of power relationships, and to focus analytic attention on the pragmatic uses of linguistic forms rather than on language as a fixed and formal set of features or cultural categories that somehow transcend the actual social circumstances of the speech community.

Person, self and emotion

In veering away from styles of ethnographic writing that view cultures as monolithic and homogeneous and moving towards modes of writing that see human subjectivity as both social and individual, and culture as both shared and contested, cultural anthropologists have been increasingly concerned with the role that emotions and talk about emotions play in social life, and with the possibility of an anthropology of experience that would convey the distinctive qualities of life in another culture while at the same time portraying an individual's complex and often contradictory experiences within that culture. Earlier work, beginning with that of Ruth Benedict (1934), for example, saw both

personality and culture as consistent unified wholes. More recent analyses of the language of personal narrative, of cultural discourses of emotion, of life history, of the micropolitics of everyday life, and psychoanalytic modes of analysis have all contributed to the effort to write convincingly of the fluidity and contextuality of the self and of culture.

cultural geography

Cultural geography is concerned with understanding the diversity of human cultures across the surface of the earth and with exploring the spatial constitution of cultural difference. Its origins can be traced to the nineteenth-century German conception of *Kultur* (referring to the specific and variable cultures of different nations and periods). The geographical expression of culture in the landscape was central to the German tradition of *Landschaftskunde,* an approach that was assimilated and transformed in North America through the work of Carl Sauer (1889–1975) and his students at what became known as the 'Berkeley school'. Sauer was implacably opposed to environmental determinism and approached the study of landscape change as an indication of the scope of human agency in transforming the face of the earth (Thomas 1956). To investigate such transformations, Sauer used a range of evidence including settlement patterns, the domestication of plants and animals, the distribution of material artefacts and the diffusion of innovations. Drawing on the work of contemporary anthropologists such as Alfred Kroeber and Robert Lowie, Sauer (1925:46) distinguished between natural and cultural landscapes, arguing that, 'The cultural landscape is fashioned out of a natural landscape by a culture group. Culture is the agent, the natural area is the medium, the cultural landscape the result.'

Sauer's work is still widely respected for his command of languages and dedication to fieldwork, his emphasis on human agency and ecological concern, and his scorn for narrow disciplinary boundaries. But his work has been criticized for its static, disembodied, 'superorganic' theory of culture (Duncan 1980) and for its antiquarian preoccupation with rural landscapes of the distant past (Cosgrove and Jackson 1987). Cultural geographers in Britain and North America have challenged Sauer's unitary view of culture, suggesting that landscapes are contested cultural constructions, socially invested with conflicting meanings that derive from different material interests. Treating landscapes as a reflection of diverse ways of seeing, new methods of interpretation have arisen, including studies of the iconography of landscape and the relationship between social formation and landscape symbolism (Cosgrove 1984; Cosgrove and Daniels 1988).

Reflecting the 'cultural turn' throughout the social sciences and the humanities, cultural geographers have begun to explore post-structuralist concerns with discourse and text, developing a sensitivity to the politics of representation (Barnes and Duncan 1992; Duncan and Ley 1993). Some have also been influenced by developments in feminist theory and cultural studies, concerning the cultural politics of gender and sexuality, language, race and nation, as these are played out across the contested boundaries of public and private space (Jackson 1989). Such departures from the Berkeley school tradition have not been universally welcomed (see Price and Lewis 1993 and subsequent commentaries).

As people's experiences of environment and nature are increasingly mediated through television and popular culture, places have come to be recognized as the product of

invented traditions (Anderson and Gale 1992). Unitary definitions have given way to a plurality of conflicting cultures and to a conception of modern identities as inherently hybrid. These developments have led to a more sharply politicized conception of cultural geography in which notions of ideology and power now play a central role. Cultural geographers have returned to the question of nature, bringing new perspectives such as ecofeminism, psychoanalysis and post-modernism to issues that were originally raised by Berkeley school scholars such as Clarence Glacken (1967). Cultural geography is also coming to terms with its historical links with imperialism, exploring a range of post-colonial debates over issues such as native land rights. The diversity of cultural geography truly reflects the contested nature of its core concept, culture, which, as Raymond Williams (1976:87) observed, is 'one of the two or three most complicated words in the English language'.

cultural history

The term cultural history came into use in the late eighteenth century, originally in Germany, inspired by the attempts of Herder, Hegel and others to view the different parts

of culture as a whole (histories of literature, art and music go back much further). The most famous nineteenth-century example of the genre was the Swiss scholar Jacob Burckhardt's *Civilization of the Renaissance in Italy* (1860), which was concerned not so much with painting or literature as with attitudes, notably with individualism, with the admiration for antiquity, with morality and with festivals and even the organization of the state as 'works of art'. In the early twentieth century, the Dutch historian Johan Huizinga produced a masterly study of Franco-Flemish culture, *The Waning of the Middle Ages* (1919), more or less on the Burckhardtian model (*see* Huizinga 1959 [1929]), while in Hamburg Aby Warburg wrote a handful of important articles and built up a marvellous library (transferred to London in 1933) devoted to the history of the classical tradition and to the science of culture *(Kulturwissenschaft).* However, these attempts to write a general history of culture found few emulators. At much the same time, between the two world wars, French attempts to go beyond political and economic history took the form of the history of collective mentalities associated with the Annales School, while in the USA attention was focused on the history of ideas.

The history of culture did not go uncriticized. Marxists in particular pointed out that the classical studies of cultural history depend on a postulate which it is extremely difficult to justify, the postulate of cultural unity or consensus. Thus Burckhardt wrote of 'the culture of the Renaissance', while Huizinga once described history as the form in which 'a culture accounts to itself for its past'. In similar fashion, the non-Marxist Ernst Gombrich rejected the work of Burckhardt and Huizinga on the grounds that it was built on 'Hegelian foundations' which had 'crumbled' (Gombrich 1969).

The rise or revival of interest in a holistic history of culture goes back to the 1970s or thereabouts, a time of reaction against socioeconomic determinism and archive positivism. Just as late eighteenth-century historians were inspired by Herder and Hegel, so late twentieth-century historians—especially in France and the USA—draw on cultural anthropology (especially on Clifford Geertz, whose essay on the cock-fight is cited again and again), and on cultural theory more generally. The ideas of Lévi-Strauss evoked some response from historians in the 1970s, but the influence of Elias, Bakhtin, Foucault and Bourdieu has been considerably more substantial and long-lasting, while a few brave souls are attempting to make use of Derrida.

In recent work, the term culture has extended its meaning to embrace a much wider range of activities. Historians study popular culture as well as elite culture. They are concerned not only with art but also with material culture, not only with the written but also with the oral, not only with drama but also with ritual. The idea of political culture stretches the concept still further. Everyday life is included, or more precisely the rules or principles underlying everyday practices.

Traditional assumptions about the relation between culture and society have been reversed. Cultural historians, like cultural theorists, now claim that culture is capable of resisting social pressures or even that it shapes social reality. Hence the increasing interest in the history of representations (whether verbal or visual), the history of the imaginary, and especially the story of the construction, invention or constitution of what used to be considered social facts such as social class, nation or gender.

Another approach, partly inspired by anthropology, focuses on cultural encounters, clashes or invasion. Historians have attempted to reconstruct the way in which the Caribs

perceived Columbus, the Aztecs saw Cortés, or the Hawaiians viewed Captain Cook and his sailors. The point to emphasize here is the relatively new interest in the way in which the two sides understood or failed to understand one another. There is also increasing interest in the process of borrowing, acculturation, reception, and resistance, in cases of encounters not only between cultures but also between groups within them.

cultural studies

John Fiske (1992) maintains that 'culture' (in cultural studies) 'is neither aesthetic nor humanist in emphasis, but political'. Thus, the object of study in cultural studies is not culture defined in the narrow sense, as the objects of aesthetic excellence ('high art') nor culture defined in an equally narrow sense, as a process of aesthetic, intellectual and spiritual develop-ment, but culture understood, in Raymond Williams's (1961) famous appropriation from anthropology, as 'a particular way of life, whether of a people, a period or a group'. This is a definition of culture which can embrace the first two definitions, but also, and crucially, it can range beyond the social exclusivity and narrowness of these, to include the study of popular culture. Therefore, although cultural studies cannot (or should not) be reduced to the study of popular culture, it is certainly the case that the study of popular culture is central to the project of cultural studies. Finally, cultural studies regards culture as political in a quite specific sense, one which reveals the dominant political position within cultural studies. Stuart Hall (1981), for example, describes popular culture as

an arena of consent and resistance. It is partly where hegemony arises, and where it is secured. It is not a sphere where socialism, a socialist culture—

already fully formed—might be simply 'expressed'. But it is one of the places where socialism might be constituted. That is why 'popular culture' matters.

Others within cultural studies might not express their attitude to popular culture quite in these terms, but they would certainly share Hall's concern to think of culture politically.

All the basic assumptions of cultural studies are Marxist. This is not to say that all practitioners of cultural studies are Marxists, but that cultural studies is itself grounded in Marxism. Marxism informs cultural studies in two fundamental ways. First, to understand the meanings of culture we must analyse it in relation to the social structure and its historical contingency. Although constituted by a particular social structure with a particular history, culture is not studied as a reflection of this structure and history. On the contrary, cultural studies argues that culture's importance derives from the fact that it helps constitute the structure and shape the history. Second, cultural studies assumes that capitalist industrial societies are societies divided unequally along ethnic, gender, generational and class lines. It is argued that culture is one of the principal sites where this division is established and contested: culture is a terrain on which takes place a continual struggle over meaning, in which subordinate groups attempt to resist the imposition of meanings which bear the interests of dominant groups. It is this which makes culture ideological.

Ideology is without doubt the central concept in cultural studies. There are many competing definitions of ideology, but it is the formulation established by Hall (1982), which is generally accepted as the dominant definition within cultural studies. Working within a framework of Gramsci's (1971) concept of hegemony, Hall developed a theory of 'articulation' to explain the processes of ideological struggle (Hall's use of 'articulation' plays on the term's double meaning: to express and to join together). He argues that cultural texts and practices are not inscribed with meaning, guaranteed once and for all by the intentions of production; meaning is always the result of an act of 'articulation' (an active process of production in use). The process is called articulation because meaning has to be expressed, but it is always expressed in a specific context, a specific historical moment, within a specific discourse(s). Thus expression is always connected (articulated) to and conditioned by context. Hall also draws on the work of the Russian theorist Valentin Volosinov (1973 [1929]) who argues that meaning is always determined by context of articulation. Cultural texts and practices are 'multi-accentual', that is, they can be articulated with different accents by different people in different contexts for different politics. Meaning is therefore a social production: the world has to be made to mean. A text or practice or event is not the issuing source of meaning, but a site where the articulation of meaning—variable meaning(s)—can take place. Because different meanings can be ascribed to the same text or practice or event, meaning is always a potential site of conflict. Thus the field of culture is for cultural studies a major site of ideological struggle; a terrain of incorporation and resistance; one of the sites where hegemony is to be won or lost.

There are those, within and outside cultural studies, who believe that cultural studies' model of ideological struggle leads (in some versions almost inevitably) to an uncritical celebration of popular culture: 'resistance' is endlessly elaborated in terms of empowerment and pleasure, while incorporation is quietly forgotten. An advocate of this

thesis is Jim McGuigan (1992), who claims to identify 'an *uncritical* populist drift' within cultural studies; an uncritical celebration of the 'popular' reading. Against this, cultural studies would insist that people *make* popular culture from the repertoire of commodities supplied by the cultural industries. Cultural studies would also insist that making popular culture ('production in use') can be empowering to subordinate and resistant to dominant understandings of the world. But this is not to say that popular culture is always empowering and resistant. To deny the passivity of consumption is not to deny that sometimes consumption is passive; to deny that the consumers of popular culture are not cultural dupes is not to deny that at times we can all be duped. But it is to deny that popular culture is little more than a degraded culture, successfully imposed from above, to make profit and secure ideological control. The best of cultural studies insists that to decide these matters requires vigilance and attention to the details of the production, distribution and consumption of culture. These are not matters that can be decided once and for all (outside the contingencies of history and politics) with an elitist glance and a condescending sneer. Nor can they be read off from the moment of production (locating meaning, pleasure, ideological effect, etc., in, variously, the intention, the means of production or the production itself). These are only aspects of the contexts for production in use, and it is, ultimately, in production in use that questions of meaning, pleasure, ideological effect, and so on can be (contingently) decided.

culture

Culture is one of the basic theoretical terms in the social sciences. In its most general sense within the social sciences, culture refers to the socially inherited body of learning characteristic of human societies. This contrasts with the ordinary meaning of the term, which refers to a special part of the social heritage having to do with manners and the arts. Both the ordinary and the social science uses are derived from the Latin *cultura,* from the verb *colere,* 'to tend or cultivate'. An excellent history of the term culture can be found in Kroeber and Kluckhohn's (1963) classic work, *Culture: A Critical Review of Concepts and Definitions.*

In the social sciences the term culture takes much of its meaning from its position within a model of the world which depicts the relations between society, culture and the individual.

The social science model

Human society is made up of individuals who engage in activities by which they adapt to their environment and exchange resources with each other so that the society is maintained and individual needs are satisfied.

These activities are learned by imitation and tuition from other humans, and hence are part of the social heritage, or culture, of a society. These learned activities persist from generation to generation with only a small degree of change unless external factors interfere with the degree to which these activities succeed in satisfying social and individual needs.

Learned activities are only one part of the society's culture. Also included in the social heritage are *artefacts* (tools, shelters, utensils, weapons, etc.), plus an ideational complex of constructs and propositions expressed in systems of *symbols,* of which natural *language* is the most important. By means of symbols it is possible to create a rich

variety of special entities, called culturally constructed objects, such as money, nationhood, marriage, games, laws, etc., whose existence depends on adherence to the rule system that defines them (D'Andrade 1984). The ideational systems and symbolic systems of the social heritage are necessary because human adaptive activities are so complex and numerous that they could not be learned and performed without a large store of knowledge and a symbolic system to communicate this knowledge and co-ordinate activities.

Much, but not all, of the social heritage or culture has a normative character; that is, the individuals of a community typically feel that their social heritage—their ways of doing things, their understandings of the world, their symbolic expressions—are proper, true and beautiful, and they sanction positively those who conform to the social heritage and punish those who do not.

Individuals perform the activities and hold the beliefs of their social heritage or culture not just because of sanctions from others, and not just because they find these activities and beliefs proper and true, but because they also find at least some cultural activities and beliefs to be motivationally and emotionally satisfying.

In this formulation of the model the terms social heritage and culture have been equated. The model ascribes to culture or social heritage the properties of being socially and individually adaptive, learned, persistent, normative, and motivated. Empirical consideration of the content of the social heritage leads directly to an omnibus definition of culture, like that given by Tylor: 'Culture…is that complex whole which includes knowledge, belief, art, law, morals, custom, and any other capabilities and habits acquired by man as a member of society (1958); that is, to an enumeration of the kinds of things that can be observed to make up the social heritage.

However, many social scientists restrict the definition of culture to only certain aspects of the social heritage. Most frequently, culture is restricted to the non-physical, or mental part of the social heritage. The physical activities that people perform and the physical artefacts they use are then treated as consequences of the fact that people learn, as part of their social heritage, how to perform these activities and how to make these artefacts. Treating actions and artefacts as the result of learning the social heritage gives causal efficacy to culture; in such a definition culture not only is a descriptive term for a collection of ideas, actions and objects, but also refers to mental entities which are the necessary cause of certain actions and objects.

The current consensus among social scientists also excludes emotional and motivational learnings from culture, focusing on culture as knowledge, or understandings, or propositions. However, it is recognized that some cultural propositions may arouse strong emotions and motivations; when this happens these propositions are said to be internalized (Spiro 1987).

Some social scientists would further restrict the term culture to just those parts of the social heritage which involve representations of things, excluding norms or procedural knowledge about how things should be done (Schneider 1968). Other social scientists would further restrict the definition of culture to symbolic meanings, that is, to those symbolic representations which are used to communicate interpretations of events. Geertz (1973), for example, uses this further restriction of the social heritage not only to exclude affective, motivational and normative parts of the social heritage, but also to argue

against the notion that culture resides *in* the individual. According to Geertz, culture resides in the intersubjective field of public meaning, perhaps in the same transcendent sense in which one might speak of algebra as something that exists outside of anyone's understanding of it (Geertz 1973).

Many of the disagreements about the definition of culture contain implicit arguments about the causal nature of the social heritage. For example, there is a controversy about whether or not culture is a 'coherent, integrated whole', that is, whether or not any particular culture can be treated as 'one thing' which has 'one nature'. If it were found that cultures generally display a high. degree of integration, this would be evidence that some causal force makes different parts of the culture consistent with one another. However, social scientists are now more likely to stress the diversity and contradictions to be found among the parts of a culture. Although almost any element of the culture can be found to have multiplex relations to other cultural elements (as Malinowski (1922), in his great book, *Argonauts of the Western Pacific,* demonstrated), there is little evidence that these relations ever form a single overall pattern which can be explicitly characterized, Ruth Benedict's (1934) *Patterns of Culture* notwithstanding.

Issues involving the integration of culture are related to issues concerning whether or not culture is a bounded entity. If culture is conceived of as a collection of elements which do not form a coherent whole, then the only thing that makes something a part of a particular culture is the fact that it happens to be part of the social heritage of that particular society. But if one believes that cultures are coherent wholes, then the collection of cultural elements which make up a particular culture can be bounded by whatever characterizes the whole.

The boundary issue leads in turn to the problem of sharedness, that is, if culture is not a bounded entity with its own coherence and integration, then *some* number of individuals in a society must hold a representation or norm in order for it to qualify as a part of the social heritage. However, no principled way has been found to set a numerical cut-off point. In fact, there is some evidence that cultural elements tend to fall into two types: first, a relatively small number of elements that are very highly shared and form a core of high consensus understandings (e.g. red lights mean stop); second, a much larger body of cultural elements which need to be known only by individuals in certain social statuses (e.g. a *tort* is a civil wrong independent of a contract) (Swartz 1991).

These and other problems have led to disenchantment with the term culture, along with a number of replacement terms such as 'ideology' and 'discourse'. It is not that the importance of the social heritage is being questioned within the social sciences; rather, it is that splitting the social heritage into various ontological categories does not seem to carve nature at the joints. For example, for a culture to work as a heritage—something which can be learned and passed along—it must include all kinds of physical objects and events, such as the physical sounds of words and the physical presence of artefacts— otherwise one could not learn the language or learn how to make and use artefacts. Since the cultural process necessarily involves mental and physical, cognitive and affective, representational and normative phenomena, it can be argued that the definition of culture should not be restricted to just one part of the social heritage.

Behind these definitional skirmishes lie important issues. The different definitions of culture can be understood as attempts to work out the causal priorities among the parts of

the social heritage. For example, behind the attempt to restrict the definition of culture to the representational aspects of the social heritage lies the hypothesis that norms, emotional reactions, motivations, etc. are dependent on a prior determination of what's what. The norm of generalized exchange and feelings of amity between kin, for example, can exist only if there is a category system that distinguishes kin from non-kin. Further, a cultural definition of kin as 'people of the same flesh and blood' asserts a shared identity that makes exchange and amity a natural consequence of the nature of things. If it is universally true that cultural representations have causal priority over norms, sentiments, and motives, then defining culture as representation focuses attention on what is most important. However, the gain of sharp focus is offset by the dependence of such a definition on assumptions which are likely to turn out to be overly simple.

customs unions

A customs union is a form of regional economic integration where countries join together to eliminate all barriers to their mutual trade while imposing common restrictions to trade from non-member states. Customs unions therefore imply preferential or discriminatory trade policy which conflicts with one of the basic tenets of the GATT (General Agreement on Tariffs and Trade). However, the GATT permits customs unions (Article XXIV) if they entail the removal of trade restrictions on most of the trade between members and if the average restrictiveness of external trade barriers does not increase.

In the late 1940s when the GATT was created it was generally felt that since customs unions represented a movement towards the goal of global free trade they would be economically beneficial. In the 1950s this favourable economic view was undermined by the development of the theory of second best in which the analysis of customs unions played a prominent role. Since customs unions involve the movement from one distorted allocation of resources (trade restrictions on all sources of imports) to another (trade restrictions on certain sources of imports) there can be no presumption that economic welfare will increase.

The principal contribution to the analysis of customs unions was provided by Viner (1950) who introduced the concepts of 'trade creation' and 'trade diversion'. Trade creation arises when demand which was formerly satisfied by domestic production is met by imports from a more efficient partner, leading to a saving in the real cost of satisfying a given level of demand. Trade diversion arises if the removal of internal trade restrictions results in demand which was previously satisfied by imports from the rest of the world being met by imports from the comparatively less efficient partner. There is a real cost in terms of the tariff revenue forgone. Whether a customs union is beneficial for a particular member depends upon whether on balance trade creation exceeds trade diversion. A beneficial consumption effect was later identified; the more efficiently produced output from the partner is provided at a lower price thus enabling a greater level of consumption.

Since joining a customs union may reduce welfare, why do countries not remove trade barriers to all sources of imports? The benefits of trade creation are maximized and there is no trade diversion. One answer is that countries join customs unions for non-economic reasons; for example, a desire to increase the size of the industrial sector can be satisfied

at a lower cost inside a union. Alternatively there may be economic benefits which were ignored by Viner. There may be gains from the exploitation of economies of scale, improvements in the terms of trade, greater efficiency stimulated by greater competition, increased innovation and faster growth. Further, unilateral tariff reduction directly affects only a country's imports. For that country's exports to increase it must encourage others to reduce their tariffs.

D

Darwin, Charles (1809–82)

Charles Darwin is widely regarded as the founder of modern evolutionism. Although not the first to propose a theory of the transmutation of species, his *Origin of Species* (1859) sparked the debate which converted the scientific community to evolutionism. This book not only provided the basic argument for evolution, but also proposed a new mechanism of change: natural selection. Although this mechanism remained controversial until synthesized with Mendelian genetics in the twentieth century, it has now become the basis for most biologists' approach to the question. Darwin also confronted the human implications of evolutionism in his *Descent of Man* (1871) exploring the link between humans and their ape-like ancestors and the implications of such a link for the nature of society.

Charles Robert Darwin was born in Shrewsbury, England. His father was a wealthy doctor. His grandfather, Erasmus Darwin, also a successful physician, had proposed an evolutionary theory in the 1790s. During an abortive attempt to study medicine at

Edinburgh, Darwin met the Lamarckian evolutionist R.E.Grant, who aroused his interest in fundamental biological problems. Darwin then went to Cambridge, where he studied for a BA in the expectation of becoming an Anglican clergyman, but also came into contact with the botanist John Henslow and the geologist Adam Sedgwick. After taking his degree he spent five years as ship's naturalist aboard the survey vessel HMS *Beagle* (1831–6). On the voyage he studied both the geology and zoology of South America. He soon accepted the uniformitarian geology of Charles Lyell, in which all change was supposed to be slow and gradual. He proposed important geological theories, especially on the formation of coral reefs. The fauna of the Galapagos islands (off the Pacific coast of South America) forced him to reassess his belief in the fixity of species. It was clear that closely related forms on separate islands had diverged from a common ancestor when the populations were isolated from each other.

On his return to England, Darwin spent the years 1836–42 as an active member of the scientific community in London. Family support enabled him to marry and then to set up as a country gentleman at Down in Kent. Darwin had already turned his attention to the problem of the evolutionary mechanism. He realized that evolution adapted each population to its local environment, but did not think that the Lamarckian explanation of the inheritance of acquired characteristics was adequate. He studied the techniques of artificial selection used by animal breeders and then encountered the principle of population expansion proposed in T.R.Malthus's *Essay on the Principle of Population.* This led to his theory of natural selection: population pressure created a struggle for existence in which the best adapted individuals would survive and breed, while the least adapted would die out. The extent to which the selection theory embodies the competitive ethos of capitalism remains controversial. Darwin wrote outlines of his theory in 1842 and 1844, but had no intention of publishing at this time. Although now affected by a chronic illness, he continued his researches. He studied barnacles, in part to throw light on evolutionary problems, and also worked on biogeography. A few naturalists were informed of the evolutionary project lying behind these studies, especially the botanist J.D.Hooker. In the mid-1850s he realized the significance of divergence and specialization in evolution and began to write an account of his theory for publication. This was interrupted by the arrival in 1858 of A.R.Wallace's paper on natural selection, which prompted Darwin to write the 'abstract' which became the *Origin of Species.*

The *Origin* aroused much controversy, but Darwin had primed a group of sympathetic naturalists, including J.D.Hooker and T.H.Huxley, who ensured that his theory would not be dismissed. By 1870 the general idea of evolution was widely accepted, although natural selection remained controversial. Both scientists and non-scientists found natural selection too harsh a mechanism to square with their religious and philosophical beliefs. Darwin himself accepted a role for Lamarckism, and this mechanism became widely popular in the late nineteenth century. Much evolutionary research was based on an attempt to reconstruct the tree of life from anatomical and paleontological evidence, but Darwin's own later work concentrated on botany, explaining the origin of various structures in plants in terms of natural selection. He also studied the effects of earthworms upon the soil.

Darwin had become aware of the human implications of evolutionism in the 1830s, but avoided this topic in the *Origin* to minimize controversy. His *Descent of Man* of 1871

was the first detailed attempt to explain the origin of the human race in evolutionary terms and to explore the implications of this approach for human affairs. Darwin used T.H.Huxley's work as evidence that the human species was closely related to the great apes. Much of his book took it for granted that mental and social evolution were progressive. Darwin was convinced that the white race was the most advanced, while darker races were closer to the ancestral ape. Yet he also pioneered ideas about human origins that would not be taken seriously until the mid-twentieth century. He identified Africa rather than Asia as the most probable centre of human evolution and proposed that the key breakthrough separating the ape and human families was the latter's adoption of bipedalism. This freed the hands for making weapons and tools, introducing a selection for intelligence and a consequent increase in the size of the brain. He explained the moral faculties as rationalizations of the instinctive behaviour patterns that had been programmed into our ancestors because of their social life. His *Expression of the Emotions in Man and the Animals* (1872) explained many aspects of human behaviour as relics of our animal ancestry.

decision making

In a sense, the study of decision making is so fundamental to social science that all of its disciplines have some claim to contribute to our knowledge of how decisions are, or should be, made. Throughout the twentieth century, some of these themes have come to be studied under the heading of a single discipline known as decision theory. Many of the key contributions come from experts in mathematics, philosophy, economics and psychology and partly because of this strong interdisciplinary theme, the subject has not

found an obvious institutional foothold in the university system. North America is an exception to this, though there is a tendency for university departments to focus on decision science, which is perhaps better understood as a branch of operations research. With these caveats in mind, an interpretation of decision theory broad enough to take in contributions from game theory's insights into strategic choice (decisions made in competition with reasoning agents) as well as those from the areas of organizational behaviour and sociology gives one access to a corpus of ideas that provide a bedrock for understanding the logic of reasoned (and sometimes seemingly unreasoned) action in most human spheres.

Mathematical and qualitative analyses of decision making emphasize different aspects of decision making, but there are three themes that recur. First, there are questions about the appropriate modelling of risk and uncertainty. Second, it is recognized that options need to be evaluated according to a number of different, potentially incommensurable criteria. Third, there are questions about the meaning (and truth) of the assumption that human agents are rational. A fourth issue arises in practice and concerns the apparent gap between planning (rational decision making) and the implementation of those plans within organizations (Langley 1991). We deal with each in turn.

Decision theorists are particularly interested in how decision makers cope with uncertainty. Probability theory provides the basic tools, but there are a number of ways in which the concept can be interpreted and each has pros and cons. The practice of using the relative frequency of an event (a ratio of successes to trials) has a long history though the first theoretical account, associated with the name of Laplace, suggested that probability was a measure of ignorance concerning equally likely events (so regarded because there was insufficient reason to make any other ascription (Weatherford 1982)). To the question, what should we do when relative frequencies do not exist, are undefined, or are unknown the answer is taken to be that we can think of probability as measuring belief and infer subjective probabilities from people's choices over certain gambles. The ability to infer coherent beliefs, that is, ones which satisfy basic laws of probability, depends on the truth of certain assumptions about people's preferences and their beliefs. The experimental literature that has resulted shows that the axioms of classical decision are violated both often and systematically (Baron 1988; Kahneman and Tversky 1979).

One of the classic experiments (Ellsberg 1961) to show how and when the subjective interpretation of probability might fail, also makes a direct link with the notion of uncertainty, as opposed to risk. If the term risk is reserved for situations in which probabilities can be attached to different states of the world, then it is clear that there are many situations (ranging from the adoption of some innovation through to the evaluation of environmental policy) in which even the qualitative nature of the decision problem is poorly understood, and for which probabilities are inappropriate. There is no consensus about how to model uncertainty, as opposed to risk, though ideas in Chapter 6 of Keynes's (1921) treatise have drawn considerable attention. The fact of experimental failings does not in itself touch normative claims (this is how people should behave if only they were rational) but it turns out that many of the philosophical arguments are invalid (Anand 1993).

Turning to the second issue, that of weighing up different aspects associated with options, the customary method of evaluation in economics and finance is to use some

form of cost-benefit analysis which requires the aggregation of considerations in terms of costs and benefits. Every general decision-making tool must handle situations in which different considerations must be weighed against each other even though decision makers might object to the explicitness of certain tradeoffs. An alternative, which avoids the description of attributes in monetary terms, can be found in multi-attribute utility theory (MAUT), which allows decision makers to rate options on a number of criteria. This turns out to be a useful practical tool. Often it is impossible to be precise about the relative weights given to different criteria or the criteria scores of different actions so that extensive sensitivity analysis is required: the procedure can be time-consuming but it has the merit of contributing substantially to our understanding of the dilemmas and conflicts in a decision problem. An unexpected finding by those using such tools with decision makers (Phillips 1984) is that the process of using them helps foster consensus and commitment, the absence of which can undermine even the most sophisticated planning systems.

The assumption that humans are rational is often the occasion for more heated debate than enlightened discussion. Some of this might be avoided if there were more clarity about what the assumption entails. The following list of definitions is undoubtedly partial but contains those that recur most frequently. An older philosophical view (which still curries favour in lay circles) is that rationality identifies things which we ought to pursue—though the rise of countries and supranational states where cultural diversity is the norm sees this view on the wane. An alternative, more widely accepted, 'instrumental' view is that rationality is about choosing means appropriate to ends, whatever the ends are. A third possibility, due to Herbert Simon (1955), is implied by the observation that human beings are not *maximizers* of anything given: that they are cognitively limited and seek only to satisfy their desires within the bounds of expectation. Another view, namely that rational agents have transitive preferences (if you prefer *a* to *b,* and *b* to *c,* then you also prefer a to c), predominates in the higher reaches of economic theory. Yet more accounts of what it is rational to do can be found in game theory. Suffice to say, the term had no unique meaning and accusations of irrationality are made at the risk of not understanding the logic that underpins a particular behaviour.

A new discipline, known as risk studies, may be about to emerge (Turner 1994). If it does, decision theory will no doubt make an important contribution to its development though the gulf between mathematical and institutional analyses remains. There are many aspects of good decision making in practice about which decision theory has had little to say, such as the creative acts required to conceive of options (de Bono 1970). It is, for example, apparent that good risk communication is essential if increasingly publicized crises, from oil spills to faulty breast implants, are to be handled successfully, though there is no substantial body of theory to help with this as yet. A more methodological lesson that we might draw from this subject is the possibility that theories might be useful even if they are false.

defence economics

Since the beginning of the Second World War, economists have applied their tools to the study of war and the preservation of peace. Defence economics is the study of defence and peace with the use of economic analysis and methods, embracing both microeconomics and macroeconomics and including static optimization, growth theory, distribution theory, dynamic optimization, comparative statics (i.e. the comparison of equilibria) and econometrics (i.e. statistical representations of economic models). In defence economics, agents (e.g. defence ministries, bureaucrats, defence contractors, Members of Parliament, allied nations, guerrillas, terrorists and insurgents) are characterized as rational agents who seek their well-being subject to constraints on their resources and actions. As such, agents are viewed as responding in predictable fashions to alteration in their tastes or environment. Thus, for example, a terrorist, who confronts higher prices (costs) for engaging in, say, skyjackings owing to the installation of metal detectors in airports, is expected to substitute skyjackings with a related mode of attack (e.g. kidnappings) that are relatively cheaper to perform.

When analysing the behaviour of government agents (e.g. bureaucrats or elected officials), defence economists often employ public choice methods that account for the self-interests of the agents. These agents may, consequently, trade off the welfare of their constituency in the pursuit of their own well-being, incurring costs that are not justified by defence needs.

Topics relevant to defence economics include the study of arms races, alliances and burden-sharing, economic warfare, the arms trade, weapons procurement policies,

defence and development, defence industries, arms control agreements and their net benefits, the economics of treaty verification, evaluation of disarmament proposals, and defence industry conversion. Relevant studies of economic efficiency in the defence sector deal with budgeting, evaluation of alternative organizational forms, internal markets in the armed forces, recruitment, military personnel, incentive contracting, and performance indicators.

During the Cold War, much of the attention of defence economists focused on the following issues: defence burdens and their impact on economic growth; defence burden sharing among allied nations; the measurement and instability of arms races; the efficient allocation of resources within the defence sector; and the regional and national impact of defence spending on income distribution. In the post-Cold-War era, researchers have focused their attention on industrial conversion, the resource allocative aspects of disarmament, the economics of peacekeeping forces, and the measurement of a peace dividend.

When applying economic methods to defence economic issues, researchers must take into account the unique institutional structures of the defence establishment. Thus, for example, cost-plus contracts make more sense when one realizes that the buyer (e.g. the Ministry of Defence) may reserve the option to change the performance specification of a weapon system at a later stage. Institutional considerations are relevant to procurement practices, arms trade policies, defence industries' performance, alliance burden sharing, defence and growth, and a host of related defence economic topics.

Policy issues have centred around whether large allies shoulder the burdens of the small, and, if so, what can be done about it. Another policy concern involves the impact of defence spending on growth: that is, does defence promote or inhibit growth? For most developed countries, defence is expected to impede growth by channelling resources (including research scientists) away from investment. The outcome is less clear cut in developing economies where military service can train personnel and build social infrastructure. The relative profitability of the defence sector has also been a policy concern, since firms tend to face little competition and may earn high profits. Another policy issue has focused on the costs and benefits of an all-volunteer military force.

defences

The conceptualization of ego mechanisms of defence presents one of the most valuable contributions that Sigmund Freud and psychoanalysis have made to psychology. Modern psychiatrists, including non-Freudians, define defence mechanisms in a more generic sense, as innate coping styles which allow individuals to minimize sudden, often unexpected, changes in internal and external environment and to resolve cognitive dissonance (psychological conflicts). Defences are deployed involuntarily, as is the case in physiological homeostasis, and in contrast to so-called coping strategies. Evidence continues to accumulate that differences in how individuals deploy defences—their unconscious coping styles—are a major consideration in understanding differential responses to environmental stress. For example, some people respond to stress in a calm, rational way, whereas others become phobic or paranoid, or retreat into fantasy. These different responses are intelligible in terms of different defences.

Sigmund Freud (1964 [1894]) suggested that psychopathology was caused by upsetting affects, or emotions, rather than disturbing ideas. Freud observed that the ego's defence mechanisms can cause affects to become 'dislocated or transposed' from particular ideas or people, by processes that Freud later called dissociation, repression and isolation. In addition, affects could be 'reattached' to other ideas and objects through processes called displacement, projection and sublimation.

Freud identified four significant properties of the defences: they help manage instincts and affects; they are unconscious; they are dynamic and reversible; and although the hallmarks of major psychiatric syndromes, in most people they reflect an adaptive, not a pathological, process.

The use of defence mechanisms usually alters the individual's perception of both internal and external reality. Awareness of instinctual 'wishes' is often diminished; alternative, sometimes antithetical, wishes may be passionately adhered to. While ego mechanisms of defence imply integrated and dynamic—if unconscious—psychological processes, they are more analogous to an oppossum playing dead in the face of danger than to a reflexive eye-blink or to conscious tactics of interpersonal manipulation.

Some inferred purposes of ego mechanisms of defence are: first, to keep affects within bearable limits during sudden changes in one's emotional life (for example, following the death of a loved one); second, to restore psychological homeostasis by postponing or deflecting sudden increases in biological drives (such as heightened sexual awareness and aggression during adolescence); third, to create a moratorium in which to master critical life changes (for example, puberty, life-threatening illness, or promotion); and fourth, to handle unresolved conflicts with important people, living or dead.

In 1936, Freud advised the interested student: 'There are an extraordinarily large number of methods (or mechanisms, as we say) used by our ego in the discharge of its defensive functions…My daughter, the child analyst, is writing a book upon them.' He was referring to his eightieth-birthday present from Anna Freud; her monograph, *The Ego*

and the Mechanisms of Defense (1937), is still the best single reference on the subject.

delusions

Although the notion that a bizarre or irrational belief may reflect a state of insanity has a long history (Sims 1988), most contemporary accounts of delusions have been influenced by the work of the Heidelberg school of psychiatry, particularly Karl Jaspers (1963 [1912]). Jaspers advocated a phenomenological approach in which the clinician attempts to understand mental *ill*ness by empathizing with the patient and sharing the patient's experiences. On his view, the hallmark of psychotic illness is that it is not amenable to empathy and is therefore ultimately *ununderstandable.* Jaspers observed that abnormal beliefs in general are held with extraordinary conviction, are impervious to counter-argument, and have bizarre or impossible content. However, he further distinguished

between *delusion-like ideas,* which arise understandably from the individual's personality, mood or experiences, and *primary delusions,* which arise suddenly from a more fundamental change of personality and which are not mediated by inference. The American Psychiatric Association (1987) defined a delusion as simply

> A false personal belief based on incorrect inference about external reality that is firmly sustained despite of what almost everyone else believes and despite what constitutes incontrovertible and obvious proof or evidence to the contrary. The belief is not one ordinarily accepted by other members of the person's culture or subculture.

The concept of *paranoia* has been used to describe psychotic disorders in which delusions (particularly of persecution) are the main feature. Kraepelin (1907), also a Heidelberg psychiatrist who had a major influence on the development of modern systems of psychiatric classification, initially took the view that dementia paranoides was a discrete type of psychotic disorder but later held that it was a subtype of dementia praecox (renamed schizophrenia by Bleuler). The American Psychiatric Association (1994) now uses the term *delusional disorder* to describe schizophrenia-like illnesses in which delusions are the main feature.

Delusions observed in clinical practice tend to concern themes of persecution, reference (when a patient believes that apparently meaningless or innocuous events, comments or objects refer to the self) or grandiosity (Sims 1988). Morbid jealousy (characterized by a delusion that a loved one is being unfaithful) and misidentification syndromes (for example, the Capgras syndrome in which a patient believes that a loved one has been replaced by an impostor) are less often observed (Enoch and Trethowan 1979).

The social context of delusional thinking has hardly been investigated, although Mirowsky and Ross (1983) have suggested that paranoid ideation is particularly evident in social and economic circumstances characterized by powerlessness. Following his analysis of the memoirs of Daniel Schreber, a German judge who suffered from a severe mental illness, Freud (1958 [1911]) suggested that paranoia is a product of homosexual longings which are unacceptable to consciousness. This theory has been disputed by other commentators who have attributed Schreber's illness to the authoritarian childrearing practices advocated by his father (Schatzman 1973).

Two further accounts of delusional thinking have been proposed in the psychological literature. Maher (1974) has suggested that delusions are the product of rational attempts to explain anomalous experiences including abnormal bodily sensations; on this view the reasoning of deluded people is normal. Although perceptual abnormalities do seem to be implicated in some types of delusions (particularly the misidentification syndromes; cf. Ellis and Young 1990), empirical studies have failed to establish a general relationship between anomalous experiences and abnormal beliefs (Chapman and Chapman 1988).

Other psychologists have argued that reasoning processes may be abnormal in deluded patients and recent empirical studies would tend to support this view. Garety *et al.* (1991) have shown that many deluded patients perform abnormally on probabilistic reasoning tasks, sampling less evidence before making a decision than non-deluded controls.

Taking a different approach, Bentall *et al.* (1994) have shown that deluded patients have an abnormal tendency to explain negative experiences by reference to causes which are external to self. This attributional style, which seems to reflect the abnormal functioning of a normal defensive mechanism, is hypothesized to protect the deluded individual from low self-esteem. This account is consistent with the view that paranoia is a camouflaged form of depression (Zigler and Glick 1988).

There is evidence that cognitive-behavioural strategies may be effective in the treatment of some kinds of delusional beliefs (Chadwick and Lowe 1990).

demand for money

The demand for money has often played a central role in the debate concerning the appropriate stance for monetary policy. Changes in the money supply have a direct impact on interest rates, which provides the first link in the chain of the monetary transmission mechanism. Monetarists believe that the money supply has an effect on real output in the short run (three to five years) but in the long run real output returns to its 'natural rate' and any monetary expansion is dissipated in price rises (inflation). In an open economy the money supply also influences the exchange rate and may even cause the latter to overshoot, with consequent short-run effects on price competitiveness, exports, imports and hence real output.

In analysing money demand we assume that in the long run, desired nominal money holdings rise one-for-one with the price level so that the purchasing power of money (i.e. real money balances) remains constant *(ceteris paribus).* In economies that suffer from hyperinflation (e.g. some Latin American countries, emerging economies of eastern Europe and Russia) the main determinant of *real* money demand is the expected rate of inflation. The higher that the latter is, the more people wish to move out of money and into goods. Here the rate of inflation represents the rate of loss of purchasing power of money or, more technically, the opportunity cost of money.

In industrialized countries (with moderate inflation rates) a key determinant of (real) money holdings is the level of (real) transactions undertaken. If the desired demand for money M^d is proportional to money income PY then $M^d=kPY$. In equilibrium money supply M^s must equal money demand so that $M^s=kPY$. Hence as long as 'k' remains constant, any increase in the money supply M^s will cause an increase in prices P or real output Y. If, in the long run, real output growth is determined by the underlying growth in productivity, then the price level rises one-for-one with an increase in the money supply.

Given the underlying growth in output and a desired path for prices and an estimate of $k,$ one can calculate the required growth of the money supply. Often debates about monetary policy are conducted in terms of the 'velocity of circulation' which is defined as *PY/M.* Given our above assumption about proportionality in the demand for money, we see that this implies that velocity is a constant (i.e. $V=1/k$).

As well as the transactions motive for holding money, we have the 'asset motive', which is based on the fact that money is a 'store of value'. Faced with the choice between two assets, money which earns interest r_m and bonds which earn interest r_b, the individual will (in general) choose to hold both assets (i.e. diversified portfolio). However, the

individual will hold more wealth in money (and less in bonds) if either the interest rate on bonds falls or the interest rate on money rises, or if bonds are perceived to have become more risky. This model of the demand for money has its origins in the so-called mean-variance approach to asset demands. If we consider the transactions motive and the asset motive together, this more complex demand for money function poses much greater problems in setting monetary targets.

To predict the demand for money consistent with a desired or feasible path for output and prices one needs to be able to predict the behaviour of the interest rate spread, namely the own rate of interest on money less the rate on bonds. Movements in this spread depend in part on the objectives (e.g. profit maximizing behaviour) of commercial banks. If the authorities by open market sales of bonds, raise interest rates on bonds in an attempt to reduce the demand (and hence supply) for money, the commercial banks may respond by raising the interest rate they pay on large deposits (e.g. certificates of deposit), thus 'attracting back' the funds to the banks and keeping monetary growth high. Also, the financial sector will look for ways of creating new types of deposits (i.e. financial innovation). For example, in the USA, 'money market mutual funds' are deposits which are invested in a portfolio of short-term assets (e.g. Treasury bills, commercial bills), yet customers of the bank can easily draw cheques on such funds. In addition, if there are no capital controls, residents can either place funds in offshore banks in the home currency (e.g. US dollars of US residents held in the Caribbean) or in foreign currencies. Currency substitution may then take place between the domestic and foreign currencies. This may provide an additional source of difficulty when trying precisely to define what constitutes 'money' and in determining the demand for the domestic currency.

All in all, while the demand for narrow (i.e. transactions) and broad money (which includes savings accounts) tended to move broadly together in the 1950s and 1960s, this has ceased to be the case in the 1980s and 1990s in many industrialized countries. In technical language, the demand for money (or 'velocity') has become more unpredictable in the 1970s (UK and US broad money), the early 1980s (e.g. 'the great velocity decline' in the USA) and even in Germany, in the 1992–4 period. Hence for any given change in the money supply, it is much more difficult to predict the course of prices (inflation) over the ensuing five years (i.e. there are 'long and variable lags' in the system). This has led to a move away from sole reliance on the money supply as the means of combating inflation. Instead there has been either a move towards setting nominal interest rates (to achieve a desired level of real interest rates) in closed economies (like the USA) or in open economies, fixing the domestic exchange rate to a low inflation anchor currency (e.g. to the Deutsche Mark in European countries).

democracy

In the classical Greek *polis,* democracy was the name of a constitution in which the
poorer people (*demos)* exercised power in their own interest as against the interest of the
rich and aristocratic. Aristotle thought it a debased form of constitution, and it played
relatively little part in subsequent political thought, largely because Polybius and other
writers diffused the idea that only mixed and balanced constitutions (incorporating
monarchic, aristocratic and democratic elements) could be stable. Democracies were
commonly regarded as aggressive and unstable and likely to lead (as in Plato's *Republic)*
to tyranny. Their propensity to oppress minorities (especially the propertied) was what
Burke meant when he described a perfect democracy as the most shameless thing in the
world.

   Democracy as popular power in an approving sense may occasionally be found in early
modern times (in the radical thinkers of the English Civil War, the constitution of Rhode
Island of 1641, and in the deliberations of the framers of the American Constitution), but
the real vogue for democracy dates from the French Revolution. The main reason is that
'democracy' came to be the new name for the long-entrenched tradition of classical
republicanism which, transmitted through Machiavelli, had long constituted a criticism of
the dominant monarchical institutions of Europe. This tradition had often emphasized the
importance of aristocratic guidance in a republic, and many of its adherents throughout
Europe considered that the British constitutional monarchy with an elected parliament
was the very model of a proper republic. This idea fused in the nineteenth century with
demand to extend the franchise, and the resulting package came generally to be called
'democracy'.

   It is important to emphasize that democracy *was* a package, because the name had
always previously described a source of power rather than a manner of governing. By the
nineteenth century, however, the idea of democracy included representative parliaments,
the separation of powers, the rule of law, civil rights and other such liberal desirabilities.
All of these conditions were taken to be the culmination of human moral evolution, and
the politics of the period often revolved around extensions of the franchise, first to adult
males, then to women, and subsequently to such classes as young people of 18 (rather
than 21) and, recently in Britain, to voluntary patients in mental hospitals.

   Democracy proved to be a fertile and effervescent principle of political perfection.
Inevitably, each advance towards democracy disappointed many adherents, but the true
ideal could always be relocated in new refinements of the idea. The basis of many such
extensions had been laid by the fact that democracy was a Greek term used, for accidental
reasons, to describe a complicated set of institutions whose real roots were medieval. The
most important was representation, supported by some American founding fathers

precisely because it might moderate rather than reflect the passions of an untutored multitude. The Greekness of the name, however, continually suggests that the practice of representation is not intrinsic to modern democracy, but rather a contingent imperfection resulting from the sheer size of modern nations by comparison with ancient city states. In fact, modern constitutional government is quite unrelated to the democracy of the Greeks.

Although modern democracy is a complicated package, the logic of the expression suggests a single principle. The problem is: what precisely is the principle? A further question arises: how far should it extend? So far as the first question is concerned, democracy might be identified with popular sovereignty, majority rule, protection of minorities, affability, constitutional liberties, participation in decisions at every level, egalitarianism, and much else. Parties emphasize one or other of these principles according to current convenience, but most parties in the modern world (the fascist parties between 1918 and 1945 are the most important exception) have seldom failed to claim a democratic legitimacy. The principle of democracy was thus a suitably restless principle for a restless people ever searching for constitutional perfection.

Democracy is irresistible as a slogan because it seems to promise a form of government in which rulers and ruled are in such harmony that little actual governing will be required. Democracy was thus equated with a dream of freedom. For this reason, the nationalist theories which helped destroy the great European empires were a department of the grand principle of democracy, since everybody assumed that the people would want to be ruled by politicians of their own kind. The demographic complexities of many areas, however, were such that many people would inevitably be ruled by foreigners; and such people often preferred to be ruled on an imperial principle—in which all subjects are, as it were, foreigners—rather than on a national principle, which constitutes some as the nation, and the rest as minorities. In claiming to be democratic, rulers might hope to persuade their subjects that they ruled in the popular interest.

Democracy is possible only when a population can recognize both sectional and public interests, and organize itself for political action. Hence no state is seriously democratic unless an opposition is permitted to criticize governments, organize support, and contest elections. But in many countries, such oppositions are likely to be based upon tribes, nations or regions, which do not recognize a common or universal good in the state. Where political parties are of this kind, democratic institutions generate quarrels rather than law and order. In these circumstances, democracy is impossible, and the outcome has been the emergence of some other unifying principle: sometimes an army claiming to stand above 'politics', and sometimes an ideological party in which a doctrine supplies a simulacrum of the missing universal element. One-party states often lay claim to some eccentric (and superior) kind of democracy—basic, popular, guided and so on. In fact, the very name 'party' requires pluralism. Hence, in one-party states, the party is a different kind of political entity altogether, and the claim to democracy is merely window-dressing. This does not necessarily mean, however, that such governments are entirely without virtue. It would be foolish to think that one manner of government suited all peoples.

Democracy as an ideal in the nineteenth century took for granted citizens who were rationally reflective about the voting choices open to them. Modern political scientists have concentrated their attention upon the actual irrationalities of the democratic process.

Some have even argued that a high degree of political apathy is preferable to mass enthusiasm which endangers constitutional forms.

democratization

The process through which authoritarian regimes are transformed into democratic regimes is called democratization. It must be kept analytically distinct both from the process of liberalization and from the process of transition. Liberalization is simply the decompression of the authoritarian regime taking place within its framework. It is controlled by the authoritarian rulers themselves. It consists in the relaxation of the most heinous features of authoritarianism: the end of torture, the liberation of political prisoners, the lifting of censorship and the toleration of some opposition. Liberalization may be the first stage in the transition to democracy. However, the transition to democracy truly begins when the authoritarian rulers are no longer capable of controlling domestic political developments and are obliged to relinquish political power. At that

point, an explosion of groups, associations, movements and parties signals that the transition has started.

There is no guarantee that, once begun, a transition from authoritarianism will necessarily lead to a democratic regime. Though it will simply be impossible to restore the previous authoritarian regime, in many cases the political transition will be long, protracted and ineffective. In other cases, the major features of a democratic regime will come into being. Usually, political parties re-emerge representing the old political memories of the country or new parties are created to represent the dissenting groups and the adamant oppositions during the authoritarian regime. Depending on the tenure of the previous authoritarian regimes, there will appear different leadership groups. If the authoritarian regime has lasted for some decades, then few old political leaders retain enough social popularity and political support to be able to play a significant role in the transition and new young leaders will quickly replace them. If the authoritarian regime has lasted less than a decade, it will be possible for the political leaders ousted by the authoritarian regime to restructure their political organizations and to reacquire governmental power. During the process of democratization new institutions will be created. The once atomized and compressed society enters into a process of self-reorganization and provides the social basis for new political actors.

The reorganization of society has proved easier in non-communist authoritarian regimes. In former communist authoritarian regimes, all social organizations have been destroyed by the communist party. Only groups supporting the communist party and dominated by it were allowed to function. Few dissenting associations and movements were tolerated and allowed to be active in politics. On the contrary, in southern European and Latin American countries, the various authoritarian regimes never succeeded in destroying all forms of pluralism, or organized groups. Moreover, their rate of economic growth, though limited, created the premises of a pluralist society almost ready-made for the process of democratization. Eastern European communist authoritarian regimes collapsed in a sort of sociopolitical void. Only in Poland a powerful organized movement existed, *Solidarnosc,* that could inherit political power. Otherwise, citizens' forums and umbrella associations had to emerge while former communists slowly reorganized themselves. For these reasons, free elections have determined a new distribution of political power in eastern Europe without yet stabilizing a democratic regime.

According to Harvard political scientist Samuel P. Huntington (1991) so far there have been three waves of democratization and two reversals: the first wave took place from 1828 to 1926 and the first reverse wave from 1922 to 1942. The second wave appeared from 1943 to 1962 and the second reverse wave from 1958 to 1975. Finally, the third wave materialized starting from 1974 and is still going on. The overall process of democratization has moved from the Anglo-Saxon and northern European countries to the southern European rim and to the Latin American continent. It has now reached all eastern European and several Asian countries. Democratization is no longer a culturally bounded phenomenon and, contrary to previous periods, it has found a largely supportive international climate. Though not all newly created democratic regimes are politically stable and socioeconomically effective, they appear to have won the bitter and prolonged struggle against authoritarian actors and mentalities. Only Muslim fundamentalist movements now represent a powerful and dogmatic alternative to the attempts to

democratize contemporary regimes.

demographic transition

Demographic transition, also known as the demographic cycle, describes the movement of death and birth rates in a society from a situation where both are high to one where both are low. In the more developed economies, it was appreciated in the nineteenth century that mortality was declining. Fertility began to fall in France in the late eighteenth century, and in north-west and central Europe, as well as in English-speaking countries of overseas European settlement, in the last three decades of the nineteenth century. Fertility levels were believed to have approximated mortality levels over much of human history, but the fact that fertility declined later than mortality during demographic transition inevitably produced rapid population growth. In France this situation appeared to have passed by 1910, as birth and death rates once again drew close to each other, and by the 1930s this also seemed to be happening in the rest of the countries referred to above.

Thompson (1929) categorized the countries of the world into three groups according to their stage in this movement of vital rates (later also to be termed the vital revolution). This process was to be carried further by C.P.Blacker (1947), who discerned five stages of which the last was not the reattainment of nearly stationary demographic conditions but of declining population, a possibility suggested by the experience of a range of countries in the economic depression of the 1930s. However, it was a paper published in 1945 by Notestein, the director of Princeton University's Office of Population Research, which introduced the term demographic transition. Notestein implied the inevitability of the transition for all societies and, together with another paper published seven years

later, began to explore the mechanisms which might explain the change. Notestein argued that the mortality decline was the result of scientific and economic change, and was generally welcomed. However, fertility had been kept sufficiently high in high-mortality countries to avoid population decline only by a whole array of religious and cultural mechanisms which slowly decayed once lower mortality meant that they were no longer needed. He also believed that the growth of city populations, and economic development more generally, created individualism and rationalism which undermined the cultural props supporting uncontrolled fertility.

Demographic transition theory is less a theory than a body of observations and explanations. Coale (1973) has summarized research on the European demographic transition as indicating the importance of the diffusion of birth control behaviour within cultural units, usually linguistic ones, with diffusion halting at cultural frontiers. Caldwell (1976) has argued that high fertility is economically rewarding in pre-transitional societies to the decision makers, usually the parents, and that, if subsequent changes in the social relations between the generations mean that the cost of children outweighs the lifelong returns from them, then fertility begins to fall. The Chicago Household Economists (see Schultz 1974) place stress on the underlying social and economic changes in the value of women's time as well as on the changing marginal value of children.

After the Second World War doubt was cast as to whether the transition necessarily ended with near-stationary population growth because of the occurrence in many industrialized countries of a baby boom, but by the 1970s this was regarded as an aberrant phenomenon related largely to a perhaps temporary movement toward early and universal marriages. By this time the demographic transition's claim to be globally applicable had received support from fertility declines (usually assisted in developing countries by government family planning programmes) in most of the world with the major exceptions of Africa and the Middle East.

Although demographic transition refers to the decline of both mortality and fertility, social scientists have often employed it to refer almost exclusively to the latter phenomenon. Because the world's first persistent fertility decline began in north-west and central Europe in the second half of the nineteenth century, demographers were tempted to employ the term *second demographic transition* for subsequent large-scale movements of this type, such as the somewhat later fall of the birth rates in southern and eastern Europe or the fertility decline in much of Latin America and Asia from the 1960s. However, second demographic transition has now found acceptance as the description of the fertility decline which followed the baby boom in developed countries and which began first in those countries which earliest participated in the first demographic transition, north-west and central Europe and the English-speaking countries of overseas European settlement. Between the mid-1960s and early 1980s fertility fell by 30–50 per cent in nearly all these countries so that by the latter date fertility was below the long-term replacement level in nearly all of them and the rest of Europe as well.

Philippe Ariès (1980) wrote of 'two successive motivations for the decline of the Western birth rate', stating that, while the first had aimed at improving the chances of the children in achieving social and occupational advancement in the world, the second was parent-oriented rather than child-oriented and had in fact resulted in the dethroning of the

child-king (his term). Ariès and others agreed that in a faster changing world parents were now planning for their own futures as well as those of their children, that the process had been accelerated by later and fewer marriages and the trend towards most women working outside the home, and that it had been facilitated by the development of more effective methods of birth control, such as the pill and IUD, and readier resort to sterilization. Henri Léridon (1981) wrote of the *second contraceptive revolution,* Ron Lesthaege and Dirk van de Kaa (1986) of two *demographic transitions* and van de Kaa (1987) of the *second demographic transition.*

demography

Demography is the analysis of population variables. It includes both methods and substantive results, in the fields of mortality, fertility, migration and resulting population numbers. Demographers collect data on population and its components of change, and construct models of population dynamics. They contribute to the wider field of population studies that relate population changes to non-demographic—social, economic, political or other—factors. In so far as it reaches into population studies, demography is interdisciplinary: it includes elements of sociology, economics, biology, history, psychology and other fields. Its methods include parts of statistics and numerical

analysis. Public health officials and actuaries have had their part in its development. Most demographers have professional knowledge of one or more of these disciplines.

Population variables are of two kinds—stock and flow. The important source of information on stock variables is national censuses, whose modern form goes back to the seventeenth century in Canada, Virginia, Sweden, and a few other places, and which are now carried out periodically in nearly all countries of the world. Among the cross-sectional information collected in censuses are age and sex distribution, labour force status and occupation, and birthplace.

The flow variables, the components of population change, include birth and death registrations, initiated before the nineteenth century in Sweden and in Britain, and now routine in all industrial countries. Efforts to attain completeness are slowly making their way elsewhere. Migration statistics, collected at national frontiers, are less available and less reliable than birth and death registrations. Much additional information, including statistics of birth expectations, is collected by sample surveys.

These four sources (censuses, vital registration, migration records, and sample surveys) differ in the ease with which they may be instituted in a new country. Censuses and surveys are the easiest to initiate. With care the completeness of a census can reach 97 per cent or more. It is true that a large number of enumerators have to be mobilized (over 100,000 in the USA in 1980, over 5 million for China's 1982 census), but that is easier to arrange than the education of the entire population to the need for birth registration. The USA first attained 90 per cent complete birth records in the first quarter of the twentieth century; contemporary poor countries are unlikely to reach this level of completeness until their residents come to have need for birth certificates. Migration statistics will not be complete as long as many of those crossing international borders can conceal their movement from the immigration authorities. Apart from illegal crossings there is the difficulty that migrants are a small fraction of those passing national boundaries, the majority being tourists, persons travelling on business, commuters, and other non-immigrants. American sentiment that people ought to be able to leave their country of residence without hindrance is so strong that out-going residents are not even stopped at the border to be asked whether they intend to return.

The special characteristics of demography are the quantitative and empirical methods that it uses. Once data in the form of censuses and registrations are available, demographic techniques are needed for valid comparisons among these. Mexico has a death rate of 6 per thousand, against France's 10; this does not signify that Mexico is healthier, but only that it has a younger age distribution as a result of high fertility; standardized comparison consists in finding what Mexico's death rate would be if it had France's age distribution but retained its own age-specific rates.

Partly for purposes of comparing mortality, but originally more for the conduct of pension and insurance business, life tables were developed in The Netherlands and in Britain during the course of the eighteenth century. The first technical problem that actuaries and demographers solved was how to go from statistics of deaths and of populations exposed to probabilities of dying. With data in finite age intervals the probabilities are not uniquely ascertainable, and a variety of methods for making life tables are currently in use.

The concerns of public health have led to the improvement of mortality statistics along

many lines, including drawing up the International List of Causes of Death, now in its ninth revision. Unfortunately uniformity in applying the classification among physicians in all countries is still a distant goal. One object of the International List is the making of cause-related tables. The expectation of life in the USA is 75 years. If all deaths from cancer were eliminated this would be increased by about 3 years; elimination of all heart disease would increase the expectation by over 15 years.

Increasing populations have lower proportions of deaths than stationary populations. In effect the age distribution pivots on the middle ages as population growth slows. A sharp drop in the birth rate does not show its full effect immediately; births remain high as the large cohorts of children already born themselves come into childbearing; population growth thus has a kind of momentum. Replacement is the condition where each child is replaced in the next generation by just one child, so that ultimately the population is stationary. After birth rates fall to bare replacement a population can still increase by 60 per cent or more.

Births are not as sensitive to the pivoting of age distribution as are deaths, since the fertile ages, intermediate between childhood and old age, are a relatively constant fraction of a population. Fast-growing countries have more children below reproductive age but fewer old people. But births are greatly affected by a bulge of individuals in the reproductive ages; births in the USA have risen from about 3.1 million in the early 1970s to about 3.6 million currently, almost entirely due to change in age distribution as the large cohorts of the 1950s reach reproduction.

The pioneer in demographic methods and models was Alfred J.Lotka, who in a series of papers extending from 1907 to 1948 showed how to answer a number of questions that are still being asked. A central one was, 'How fast is a given population really growing, as determined by its age-specific birth and death rates in abstraction from its age distribution?' Any population that grows at a fixed rate for a long period develops a stable or fixed age distribution which Lotka showed how to calculate, and its increase when it reaches this stage is its intrinsic rate.

After a long period of neglect, Lotka's work came to be applied and further developed during the 1960s. It turned out that his approach could help the estimation of birth and death rates for countries of known age distribution but lacking adequate registration data.

The techniques of birth and death analysis have been carried over to migration, especially in the form of Markov chains that describe movement or transition between countries, and other areas, just as they describe transition between life and death. Such Markov chains are capable also of representing transitions between the married and single condition, among working, being unemployed, and leaving the labour force, and many other sets of states. A literature has now been built up in which changes of state, including migration, are represented by matrices, particularly easy to handle on a computer. The first extensive calculation of this kind was due to P.H.Leslie in the 1940s.

Communities living under 'primitive' conditions grow slowly; their high birth rates are offset by high deaths. The movement of a community from this condition to one of low birth and death rates as it modernizes is known as the demographic transition. Since the fall in the birth rate lags behind the fall in the death rate, very large increases can be recorded during the transition. Britain's population multiplied fourfold between the censuses of 1801 and 1901. Contemporary less developed countries are increasing even

more rapidly.

This effect of rising income is contrary to what has often been thought: that people want children and will have as many as they can afford—a view commonly attributed to Malthus, although Malthus's writings, after the first edition of his *Essay,* are much more subtle than this. Apparently at a certain point the causal mechanism flips over: for very poor people a rise of income results in a faster rate of increase; once people are better off a further rise slows their increase.

The modernization that brings down the birth rate affects subgroups of national populations at different times. In consequence the demographic transition shows itself as differential fertility: the rich, the urban and the educated have for a time lower birth rates than the poor, the rural and the illiterate in cross-sections taken during the transition. Such differentials close up as incomes generally rise and income distributions narrow.

Some of the most puzzling questions concern the causal mechanisms that lie behind contemporary demographic changes. In what degree the fall of fertility is due to education, in what degree to income, cannot yet be answered in a way that applies to all countries. Less developed countries have far greater rates of increase now than did the countries of Europe when these were at a comparable stage of development. To what extent is the difference due to higher birth rates among presently poor countries than among the poor countries of the eighteenth century, and to what extent to lower death rates? Population models can provide answers to such questions; they show that birth differences are much more influential than death differences.

More difficult are questions on the direction of causation between two variables clearly related to each other. In most advanced countries more women are working outside the home now than in the 1950s, at a time when their partners are for the most part earning higher real wages; at the same time women's fertility has diminished, when their income and that of their partners would enable them to have more children if they wanted. Is the fall in fertility the result of women seeking jobs, and so finding it inconvenient to have children, the wish to work being primary, or do they no longer wish to have children and so take jobs to fill their time? A wealth of data exists, but the techniques for answering such questions are elusive. Again, are the present low birth rates a cohort or a period phenomenon? Do they result from present generations intending to finish up with fewer births, or are they a conjunctural phenomenon due, say, to the world recession since the mid-1970s.

A task that demographers are often called on to perform is population forecasting. Professional demographers describe their statements on future population as projections, the working out of the consequences of a set of assumptions. Users believe that the assumptions are chosen by the demographers because they are realistic, and they accept the results as forecasts. Forecasting has gone through many styles, starting with extrapolation of population numbers by exponential, logistic or other curves. More acceptable is extrapolating the components of population—birth, death, and migration— and assembling the population from the extrapolated values of these. Sampling to ascertain childbearing intentions of women has been extensively tried. Demographers have no illusions about the predictability of the long-term future, but estimates made by those who have studied the past are more worthy of attention than the simple-minded extrapolations that are the alternative. Some numbers on future population are

indispensable for virtually any kind of economic planning, whether by a corporation or a government.

One aspect of the future that has become of interest to several disciplines since the mid-1980s is the relation of a deteriorating planetary environment to population growth. How far are the loss of forests, emissions of carbon dioxide and other greenhouse gases with consequent danger of global warming, thinning of the ozone layer, declining catches in the fishing areas off western Europe, due to population increase, to what extent to expanding economies, to what extent to inadequate environmental regulation? The facts are the same for everyone, but scholars of different disciplines read them differently, and come to very different conclusions.

Biology works above all with direct observation: the facts are plain to the naked eye; no sophisticated theory is needed to see that forests are invaded and destroyed by the need of increasing populations for wood and food, that crowded countries of Asia with growing economies will suffer more pollution of water, land and air if their populations continue to increase at present rates, that Africa may have been thinly settled in the past but its present population increase with stagnant economies will bring increasing misery and destruction. For many biologists population control is humankind's first priority; the US National Academy of Sciences and the Royal Society of London introduce their joint statement with the words, 'If current predictions of population growth prove accurate and patterns of human activity on the planet remain unchanged, science and technology may not be able to prevent either irreversible degradation of the environment or continued poverty for much of the world'. No vote was taken of the membership representing all the sciences, but this statement would surely have commanded the assent of a large majority

Economics finds the matter more complicated. Population growth has advantages that could well compensate for its apparent disadvantages. With more people there will be more inventive geniuses; with larger markets there will be more opportunity for division of labour and so more economic progress; once people are rich enough they will be able to use any necessary small fraction of their wealth to counter environmental damage. So it is increasing wealth rather than population control that ought to have priority.

When biology and economics find such opposite relations of population to environment, only the blandest of statements can be made without contradicting one or another scientific authority. Before such contradiction one ought to examine the contending disciplines more closely, and try to find what of their features and methods lead them to such opposite conclusions. Study of the intimate detail of the several disciplines is the only hope for breaking the deadlock, and the only way of making full use of the positive knowledge of those disciplines.

The richness of demography is in part due to the commitment of scholars from many disciplines. Actuaries developed much of the early theory, and statisticians and biostatisticians add to their work the techniques of numerical analysis and determination of error. Sociologists see population change as both the cause and the result of major changes in social structures and attitudes; they study the increase of labour force participation by women, of divorce, of single-person households, the apparently lessening importance of marriage, and the decline in fertility rates. Economists see fertility rising and falling as people try to maximize utility. Biologists employ an ecological framework relating human populations to the plant and animal populations among which they live

and on which they depend. Psychologists have brought their survey and other tools to the study of preferences of parents for number and sex of children. Historians, in a particularly happy synthesis with demography, are putting to use the enormous amount of valuable data in parish and other records to gain new insights on what happened to birth and death rates during the past few centuries.

depressive disorders

Depressive disorders are a heterogeneous group of conditions that share the common symptom of dysphoric mood. Current psychiatric classification divides major depressive

disorders into bipolar and non-bipolar categories, depending on whether there is evidence of associated manic episodes. Less severe depressive states are categorized as dysthymic, cyclothymic and atypical depressive disorders.

The diagnosis of a depressive disorder is made only when the intensity and duration of depressive symptoms exceed those usually provoked by the stresses of normal life. Major depressive episodes are characterized by a pervasive dysphoric mood, which may be associated with feelings of worthlessness, suicidal ideation, difficulty with concentration, inability to feel pleasure, and neurovegetative changes in appetite, sleep patterns, psychomotor activity and energy levels. In severe cases, psychotic symptoms may also be present.

The prevalence of depressive disorders is relatively high. Lifetime incidence is thought to be 15–30 per cent, with women affected twice as often as men.

Although the cause of depressive disorders is not known, it is probably multifactorial. A minority of cases have clear-cut origins in medical conditions. For the remaining cases, most experts would endorse a diathesis-stress model of causation. Some factor is believed to predispose the depressed person to experience the disorder, but this latent diathesis leads to overt symptomatology only when a precipitating stress occurs. Theories of causation focus on the following potentially interactive factors: genetic predisposition, personality development, losses in early life, environmental factors and learned dysfunctional patterns of cognition and interpersonal behaviour.

Precipitating factors for acute episodes are often easily identifiable events. In other cases, external stresses seem to be absent. Psychodynamic theorists maintain that even in these patients a seemingly minor event has been idiosyncratically interpreted as a major loss, or that something has led patients to recognize the dysfunctional nature of their existence. More biologically oriented investigators believe that some physiological dysfunction precipitates most episodes.

Whether the cause or the result of a depressive disorder, a number of physiological abnormalities have been associated with subgroups of depressed patients. Shortened rapid eye movement (REM) latency, an abnormally short time between the onset of sleep and the first REM sleep cycle, is well established. There is sufficient evidence of deficiencies in both the noradrenergic and serotonergic neurotransmitter systems to suggest that there may be two neurophysiological subgroups of depressed patients.

The natural history of depression is variable, reinforcing the argument that we are considering a number of disorders under this general rubric. Onset of major depressive disorders can occur at any time in the life cycle, although bipolar disorders usually appear in the second or third decades of life. Dysthymic disorders, especially those that occur in families of patients with bipolar disorder, often begin in young adulthood. Epidemiological studies suggest that the majority of depressive episodes are untreated, either resolving on their own, or developing into chronic disorders.

Treatments of depression include psychotherapies and medication. Psychoanalytically oriented psychotherapy is often employed, although without more than anecdotal evidence of success. Enthusiasm for shortterm psychotherapies in depression has been stirred by studies demonstrating success with time-limited interpersonal and cognitive therapies. The combination of interpersonal psychotherapy and medication has been shown to be more effective than either treatment alone.

Antidepressant medications which include the heterocyclic antidepressants, monoamine oxidase inhibitors, serotonin reuptake inhibitors and several novel agents are effective in as many as 80 per cent of episodes of major depression, and in many instances of dysthymic conditions. Electroconvulsive therapy remains an important treatment for life-threatening conditions, depressions refractory to drug therapy, or for people who cannot take medication safely, such as many elderly people. Long-term maintenance medication with antidepressants or mood stabilizers, such as lithium, demonstrably decreases the frequency and intensity of repeated episodes. Frequent recurrences may adversely affect the course of the illness.

The scope, nature and cause of depressive disorders may be further elucidated by the greater understanding of the relationship between depression and other psychiatric disorders that often have accompanying dysphoria, especially anxiety disorders, obsessive compulsive disorder and substance abuse disorders.

derivative markets and futures markets

A financial instrument which is derived from, or is written on, some other asset is known as a derivative and is traded on a derivatives market. The asset on which the derivative is written can be a commodity or a financial asset. While trading in derivatives based on commodities has a much longer history, the value of trading in these instruments is greatly outweighed by the value of trading in derivatives on financial assets.

The main forms of derivative instruments are forward, futures, options and swaps contracts. Forward and futures contracts involve two parties contracting to trade a particular asset at some point in the future for a price agreed now. Options contracts give the buyer the right, but not the obligation, to buy from, if it is a call option, or sell to, if it

is a put option, the writer of the contract a particular commodity or asset at some point in the future for a price agreed now. Swaps contracts involve two parties contracting to exchange cash flows at specified future dates in a manner agreed now. Forward, swaps and some types of options are traded on over-the-counter markets where the details of the contract are tailored to the specific needs of the two parties. In contrast, some other options contracts and futures are traded through organized exchanges where trading takes place at a specified location and contracts are standardized. The standardized nature of futures and exchange traded options enhances the liquidity of these markets. Almost all futures and traded options contracts are settled not by delivery of the asset but by the parties to the contract taking an offsetting position.

Trading of derivatives based on commodities through organized exchanges dates back to the nineteenth century, with the establishment of the Chicago Board of Trade in 1848 and the introduction of futures trading there in the 1860s. However, it was not until the 1970s that trading in financial derivatives through organized exchanges began. Derivative markets represent one of the major advances in financial markets since this time. The early 1970s saw the breakdown of the Bretton Woods fixed exchange rate regime. The move to floating exchange rates, together with other major changes in the global economy in the early 1970s, led to increased volatility in both exchange rates and interest rates. Such volatility is a source of uncertainty for firms and led to a demand for financial instruments which would assist risk management. Financial futures and exchange traded options were developed to help meet this demand. Within twenty years of their establishment financial futures accounted for in excess of 60 per cent of all futures trading.

The main purpose of derivative trading is to allow risk to be managed or hedged. For example, consider a firm which is selling overseas and is due to receive payment in a foreign currency in three months' time. Changes in exchange rates over the next three months could lead to the amount of domestic currency received being much less than anticipated, possibly rendering the sale a loss-making enterprise. By using currency futures the firm can remove the uncertainty associated with exchange rate movement and lock in an exchange rate for the currency to be received. When futures are used to hedge, the risk associated with the position is transferred from the hedger to the counter-party to the trade. This counter-party may be another hedger with opposite requirements or a speculator. Speculators are willing to take on the risk in the expectation that they can profit from the activity.

In addition to their hedging role, derivatives also fulfil a price discovery role. Futures prices, for example, provide a forecast of expected future asset prices. Futures prices thus provide important information which can assist the planning of both individuals and companies. While derivative markets provide important benefits in the form of hedging and price discovery, they have also been criticized. This criticism is largely due to the fact that they are attractive to speculators who are believed to have a destabilizing impact on the market for the underlying asset. However, there is little evidence to suggest that this negative view of derivatives is justified.

developmental psychology

Developmental psychology studies change in psychological structures and processes during the life cycle. Although traditionally focused on childhood and adolescence, it has extended its scope to adulthood and old age as well.

   Two factors stimulated the rise of developmental psychology towards the end of the nineteenth century. First, Darwin's claim of continuity between humans and nature revived the discussion among philosophers such as Locke, Kant and Rousseau regarding the origins of mind. It was hoped that the study of childhood would unlock the secrets of the relationship between animal and human nature. Darwin himself kept notebooks on the development of his first child, setting a trend which was to be followed by many of the great names in the discipline.

   Given Darwin's role in the genesis of developmental psychology, it is hardly surprising that biological views, in which development is regarded as the unfolding of genetically programmed characteristics and abilities, have been strongly represented in it. (Indeed, the etymological root of the word development means 'unfolding'). Typical of such views are Stanley Hall's theory that development recapitulates evolution, Sigmund

Freud's account of the stages through which sexuality develops, Arnold Gesell's belief in a fixed timetable for growth, John Bowlby's notion of attachment as an instinctive mechanism and Chomsky's model of inborn language-processing abilities. Current research on developmental neurobiology continues this tradition.

Nevertheless, those who place their faith in the influence of the environment have also had an important say in the discipline. Behaviourism, which attributes all change to conditioning, may have failed to account satisfactorily for many developmental phenomena, but its attempts to imitate the methodology of the natural sciences have left an indelible imprint on the discipline. Most developmental psychologists now eschew extreme nature or nurture viewpoints and subscribe to one form or other of interactionism, according to which development is the outcome of the *interplay* of external and internal influences.

The second factor which stimulated the growth of developmental psychology was the hope of solving social problems. Compulsory education brought about a growing realization of the inadequacy of traditional teaching methods and a call for new ones based on scientific understanding of the child's mind. The failures of nineteenth-century psychiatry prompted a search for the deeper causes of mental disturbances and crime, widely assumed to lie in childhood. The application of developmental psychology to these social problems led to the creation of cognitive, emotional and social subdisciplines, with the unfortunate side-effect that the interrelatedness of these facets of the person has often been overlooked.

In the field of *cognitive development,* the contribution of the Swiss psychologist Jean Piaget (1896–1980) has been unparalleled, though by no means unchallenged. Piaget developed his own form of interactionism (constructivism) in which the child is biologically endowed with a general drive towards adaptation to the environment or equilibrium. New cognitive structures are generated in the course of the child's ongoing confrontation with the external world. Piaget claimed that the development of thought followed a progression of discrete and universal stages, and much of his work was devoted to mapping out the characteristics of these stages. His theory is often regarded as a biological one—yet for Piaget the developmental sequence is not constrained by genes, but by logic and the structure of reality itself.

Full recognition of Piaget's work in the USA had to await a revival of interest in educational problems during the mid-1950s and the collapse of faith in behaviourism known as the cognitive revolution which followed in 1960. Subsequently, however, developmental psychologists such as Jerome Bruner challenged Piaget's notion of a solitary epistemic subject and revived ideas developed in Soviet Russia half a century before by Lev Vygotsky (1896–1934). As a Marxist, Vygotsky had emphasized the embeddedness of all thought and action in a social context; for him, thinking was a *collective* achievement, and cognitive development largely a matter of internalizing culture. His provocative ideas exert an increasing fascination on developmental psychologists. Others, however, maintain Piaget's emphasis on the child as solitary thinker, and seek to understand the development of thought by reference to computer analogies or neurophysiology.

The study of *social and emotional development* was mainly motivated by concerns over mental health, delinquency and crime. The first serious developmental theory in this

area was that of Sigmund Freud; invited to the USA by Stanley Hall in 1909, his psychoanalytic notions were received enthusiastically for a time. For Freud, however, the origin of psychopathology lay in the demands of civilization (above all the incest taboo), and no amount of utopian social engineering could—or should—hope to remove these. From 1920 onwards, American psychology increasingly abandoned Freud in favour of the more optimistic and hard-nosed behaviourism.

However, the emotional needs of children were of scant interest to behaviourists, and it was not until the 1950s that John Bowlby (1907–90) established a theoretical basis for research on this topic by combining elements of psychoanalysis, animal behaviour studies and system theory into attachment theory. Bowlby's conception of the biological needs of children was informed by a profoundly conservative vision of family life, and his initial claims about the necessity of prolonged, exclusive maternal care were vigorously challenged in the rapidly changing society of the 1960s and 1970s. Nevertheless, his work helped to focus attention on relationships in early childhood, which have now become a major topic in developmental psychology. New awareness of the rich and complex social life of young children has undermined the traditional assumption that the child enters society (becomes socialized) only *after* the core of the personality has been formed.

Critics of developmental psychology point to its tendency to naturalize middle-class, western ideals as universal norms of development, to its indifference to cultural and historical variations, and to the lack of a unified theoretical approach. However, its very diversity guarantees continued debate and controversy, and its own development shows no signs of coming to a halt.

deviance

Although the term deviance has been employed for over 300 years, its sociological meanings are rather recent and distinct. In the main, sociologists and criminologists have taken deviance to refer to behaviour that is banned, censured, stigmatized or penalized. It is often portrayed as a breaking of rules. It is considered more extensive than crime, crime being no more than a breach of one particular kind of rule, but it includes crime and its outer margins are unclear and imprecise. What exactly deviance comprises, what

it excludes, what makes it interesting, and how it should be characterized, are not settled. There have been studies of very diverse groups in the name of the sociology of deviance. There have been descriptions of the deaf, the blind, the ill, the mad, dwarves, stutterers, strippers, prostitutes, homosexuals, thieves, murderers, nudists and drug addicts. Sociologists are not in accord about whether all these roles are unified and what it is that may be said to unify them. They can appeal to no common convention within their own discipline. Neither can they turn to lay definitions for guidance. On the contrary, commonplace interpretations are often elastic, contingent and local. What is called deviant can shift from time to time and place to place, its significance being unstable.

Common sense and everyday talk do not seem to point to an area that is widely and unambiguously recognized as deviant. It is not even evident that people *do* talk about deviance with any great frequency. Instead, they allude to specific forms of conduct without appearing to claim that there is a single, overarching category that embraces them all. They may talk of punks, addicts, glue-sniffers, extremists, thieves, traitors, liars and eccentrics, but they rarely mention *deviants*. It may be only the sociologist who finds it interesting and instructive to clump these groups together under a solitary title.

The apparent elusiveness and vagueness of the idea of deviance has elicited different responses from sociologists. Some have refrained from attempting to find one definition that covers every instance of the phenomenon. They have used *ad hoc* or implied definitions that serve the analytic needs of the moment and suppress the importance of definition itself. Others, like Liazos, have questioned the intellectual integrity of the subject, alleging that it may amount to little more than an incoherent jumble of 'nuts, sluts and perverts'. Phillipson has actually described the analysis of deviance as 'that antediluvian activity which sought to show oddities, curiosities, peccadilloes and villains as central to sociological reason'.

A number of sociologists have chosen to represent 'that antediluvian activity' as important precisely because its subject is so odd: the inchoate character of deviance becomes a remarkable property of the phenomenon rather than a weakness in its description. Matza, for example, held that 'plural evaluation, shifting standards, and moral ambiguity may, and do, coexist with a phenomenal realm that is commonly sensed as deviant'. His book, *Becoming Deviant* (1969), proceeded to chart the special contours of that realm by following the passage of an archetypal deviant into its interior. In such a guise, deviance is taken to offer a rare glimpse of the fluid and contradictory face of society, showing things in unexpected relief and proportion. Garfinkel(1967), Goffman (1963) and others have taken to repairing to the deviant margins because they offer new perspectives through incongruity or strain, perspectives that jolt the understanding and make the sociologist 'stumble into awareness'. Deviants are required to negotiate problems of meaning and structure that are a little foreign to everyday life. The study of their activity may force the sociologist to view the world as anthropologically strange. Indeed, some sociologists have implicitly turned the social world inside out, making deviance the centre and the centre peripheral. They have explored the odd and the exotic, giving birth to a sociology of the absurd that dwells on the parts played by indeterminacy, paradox and surprise in social life.

Absurdity is perhaps given its fullest recognition in a number of essays by structuralists and phenomenologists. It is there asserted that deviance is distinguished by

its special power to muddle and unsettle social reality. Deviation is described by its ability to upset systems of thought and methods of classification. Deviant matters are things out of place, things that make no sense. As Scott (1972) argued, 'The property of deviance is conferred on things that are perceived as being anomalous.' The meaninglessness of deviance is thus forced to become substantially more than a simple lack of intellectual coherence in sociology. People are thought to find it disturbing, and phenomenologists have replied by turning their gaze towards the problems which disturbance can raise. The phenomenologists' difference with Marxist and radical sociologists probably turns on their emphasis on flux and disorder. Radical sociologists tend to stress the solidity of the social world and the importance of what Gouldner (1970) called 'overpowering social structures'. Phenomenologists and others tend to stress the openness and plasticity of things, arguing that social structure is actually rather delicate and negotiable.

What *is* certain is that the analysis of deviance echoes many of the unities and disunities of sociology at large. Sociological definition is not neutral and independent. It will refract wider debates, problems and pursuits. It is in this sense that sociologists do not necessarily mean the same thing when they talk of deviance. Their ideas sometimes contradict one another, although contradiction is often no more than a trick of language, an effect of the different vocabularies that have become attached to theories.

A list of examples should reveal a little of that diversity.

Probably the most elementary definition of deviance describes it as behaviour that is *statistically infrequent.* A contrast is traced between the normal, which is common, and the abnormal or deviant, which is uncommon. That definition is deployed characteristically in clinical or psychological analysis that relies on counting: normal distribution curves are drawn, and the deviant is that which falls at the poles. Those who wet their beds with unusual frequency, who are very tall or very short, who read obsessively or not at all are deviant for practical numerical purposes. It is a definition that serves well enough in certain settings, but it can sometimes fail to make sense of deviance as it is presented in everyday life. Thus, the statistically infrequent may be socially unremarked and inconsequential. The statistically frequent may be exposed to control, disapproval and stigma. What is *assumed* to be infrequent, acquiring some of its identity from that assumption, may actually be quite common. (Homosexuality, adultery and chastity are all rather more abundant than many people suppose, but they are *taken* to be unusual.) It may indeed be *beliefs* about statistical incidence that are occasionally more significant than the incidence itself. Statistical analysis can then be rephrased to produce a commentary about the interplay between ideas about deviance and convention.

A second major strand of sociological thought is *Marxism,* but many Marxists have relegated deviance to the margins of analysis. Its pettiness has been emphasized both in the explicit arguments of some sociologists and in the practical neglect of deviance by others. Deviation is commonly thought to be a process that is relatively trivial in a world that is dominated by the massive structures of political economy. It has been maintained that little can be gained from studying deviance that cannot be achieved more directly, efficiently and elegantly from the analysis of class and state. Some, like Hirst (1975), Bankowski *et al.* (1977) and Mungham, have actually reproached Marxist and radical sociologists of deviance for discussing inappropriate and minor problems. Marxists, they

claim, should concentrate on the class struggle.

When Marxists *do* explore deviance, they tend to stress its bearing on the class struggle and the state. Thus Hill (1961), Thompson (1975) and Hobsbawm (1965) have developed a social history of crime that emphasizes the scale of popular opposition to the emergence of capitalism in England. Hall *et al.* (1976), Cohen (1972) and Willis (1977) have talked of youthful deviance as 'resistance through ritual', a fleeting and probably doomed act of refusal to accede to the authority of institutions that oppress the working class. Sumner (1976) has taken the unity of deviance to stem from the censures that reside in the core of capitalist ideology; Taylor (1980) has lodged the origins of deviance in the contradictions of the ailing political economy of late capitalism in crisis; Platt (1978) and Quinney (1975) cast deviants as those who have been defeated in the class war; Box and Pearce present them as the scapegoats who divert the gaze from the major pathologies of capitalism; and so it goes on. Marxists deposit deviation in a world made up of resistance, protest and conflict. Few have occupied themselves with processes outside that world. After all, that is the world of Marxism. Lea and Young (1984) *have* ventured outside but their place within Marxism may have become a little unsure in consequence.

A third major representative strand is *functionalism,* and Talcott Parsons (1951) is the pivot of functionalism. Parsons typified one version of deviance as the disorganized phenomena that can attend institutions and individuals that have become out of joint. He argued that, as the social world changes, so its parts may move with unequal velocities and in different directions, straining against one another and creating problems of cohesion. Deviance then became activity that sprang from defective integration. It could evolve to become a new conformity; persist as a source of stress within the social system; or disappear altogether as coherence returned to society.

Parsons (1951) also focused on a very special form of deviance in his essay on the 'sick role'. He depicted illness as the status of those who should not be rewarded for occupying what could become a dangerously seductive and useless position. The sick are pampered and, without discouragement, people might learn to malinger. Illness had to be controlled by the threat of stigma.

Almost all other functionalists have diverged from Parsons's insistence on the dysfunctions of deviance. Instead, they have elected to illustrate the surprising fashion in which deviation has unintentionally buttressed the social order. Durkheim (1933) pointed to the solidarity conferred by collective sentiments outraged by the breaking of rules. Erikson (1966) wrote of how dramatized encounters between deviants and agents of social control beat the bounds of the moral community. Deviance was to be described as a dialectical foil to themes that infuse the moral centre of society. Without a vividly reproduced deviance, it was held, the centre would lose its structure and integrity. Good requires the bad, God Satan, and morality immorality. Within the borders of society, too, deviance was to be depicted as a kind of dangerous but necessary zone between major regions and classes of phenomena. The revulsion said to surround the homosexual and the hermaphrodite enforces morally charged divisions between the genders. Deviance then supports convention, and it does so in numerous ways. Bell (1960) and Merton (1957) talked of the part played by organized crime in repairing economic and political defects in the USA, suggesting that the criminal offers power, influence and services where none is provided by the respectable order. Davis (1961) remarked how prostitution

supports monogamy and bastardy primogeniture. Most functionalist essays on deviance are brief and unsystematic. Yet their recurrent theme is that deviance upholds what it seems to disrupt. Their paradox is the interesting symbiosis of rule making, rule enforcement and rule breaking.

There are other postures: feminists writing about the rooting of deviation in patriarchy; control theorists taking deviance to be the wildness that erupts when social disciplines become weak; and ecologists charting the interlacing of deviance and conformity in the lives of people who live in the same territory. Each gives rule breaking a place in a distinct theoretical environment. Each imparts a distinctiveness that is sometimes quite marked and sometimes a little superficial. Without much effort, it is quite possible to transcribe some of those definitions so that they begin to resemble one another more closely. Thus functionalism resonates the assertions made by Marxists about the interdependence of crime and capitalism, by feminists about the links between patriarchy and rule breaking, and by phenomenologists about the work done in the social regulation of anomaly.

The sociology of deviance has probably been allied most prominently to the symbolic interactionism, labelling theory and phenomenology that came to the fore in the 1960s. So intimate is that connection that the sociology of deviance is often taken to be a wholly interactionist undertaking, bearing with it a crowd of unstated assumptions about methods, history and focus. *Deviance* is then held to refer not only to rule breaking but also to a special method of interpreting rule breaking. Those who chose to explore deviance in the late 1950s, 1960s and 1970s sought to advertise their distance from criminologists described as positivist and correctionalist. They took their task to be the symbolic reconstruction of deviance, learning how rule breaking had become possible, what meanings it attained, and how it progressed from stage to stage. The cast of performers was enlarged to include all those who significantly affected critical passages in the evolution of deviant histories. The influence of people and events was held to change with each new phase, being interpreted and reinterpreted by participants. Developments were thought to be intelligible only within the emergent logic of an unfolding career. The importance of interpretation, the processual character of social life and the centrality of deviant identity led interactionists to redefine deviation as a moving transaction between those who made rules, those who broke rules and those who implemented rules. Deviance was held to be *negotiated* over time, its properties reflecting the practical power and assumptions of those who propelled it from phase to phase. At the very core of the negotiating process are deviants themselves, and their conduct responds to the attitudes which are taken towards them at various junctures. Becoming deviant entails a recasting of the self and a redrafting of motives. It entails a supplying of accounts, meanings, purposes and character. In that process, deviant and conventional identities are manufactured, and the interactionist sociologists of deviance furnished portrait after portrait of hustlers, police officers, prostitutes, delinquents and drug users. Their work continues although it has become a little overshadowed by more recent models of conduct.

In retrospect, it is clear that the chief importance of the word deviance was connotative rather than denotative. It signified the break made in the 1960s by sociologists who sought symbolically to distance themselves and their work from what was taken to be the

excessive positivism and correctionalism of orthodox criminology. In the American Society for the Study of Social Problems and the British National Deviancy Conference, in the writings of Howard Becker (1963), David Matza and Stanley Cohen, there was an attempt to champion a new beginning for criminology, a beginning that conceived rule breaking processes to be meaningful and emergent, that did not judge or refrain from making conventional moral and political judgements, and that attached importance to the consequences of the signifying work performed by audiences and by representatives of the state in particular. What was actually studied tended, in the main, to be much the same as before, although there was a new attention to rule making and rule enforcement.

The effects of the new sociology of deviance were profound. They fed into orthodox criminology and made it rather less analytically threadbare and empiricist. But, conversely, the sociology of deviance itself began to take on some of the political and moral preoccupations it had once derided. In the 1980s, especially, civil disorder, social disorganization, crimes against women and children, and victim surveys persuaded many sociologists that correctionalism and social intervention were not really inappropriate responses to the sufferings of victims, and of female, young and black victims above all. The distinctions between crime and deviance, and between criminologists and sociologists of deviance, blurred and faded, no longer seeming to be of such great interest, and the very word deviance itself acquired a somewhat dated ring.

Dewey, John (1859–1952)

John Dewey was born in 1859. He was a child of pre-industrial New England, born and raised in Burlington, Vermont, where his father was a storekeeper, and where Dewey himself would grow to maturity and eventually attend the University of Vermont at age 16 (Wirth 1989). Graduating in 1879, Dewey became a high school teacher. Within three years, however, he entered into a doctoral programme at Johns Hopkins University. Dewey took only two years to complete his doctoral studies, which culminated with a dissertation on Kant's psychology. His first academic appointment was at the University of Michigan as an instructor of psychology and philosophy. In 1884 he moved to the University of Chicago, where he put a great deal of energy into the development of a laboratory school that allowed him to test his school-related ideas against the actual experience of teaching children (see *School and the Society,* 1902). But in 1905, in a squabble over the leadership of the laboratory school, Dewey left Chicago for Columbia University. He remained at Columbia until his retirement and died in New York City at the age of 92.

During his long life, Dewey engaged in a philosophy that not only addressed traditional philosophic pursuits in logic, ethics, political science, religion, psychology and aesthetics, but also spoke to issues in the public arena. Dewey, for instance, had substantive things to say about issues related to the suffragette movement, labour unions, birth control, world peace, social class tensions and societal transformations in Mexico, China and Russia (Dworkin 1954). A complete corpus of Dewey's work has been captured in a thirty-seven volume edition edited by Jo Ann Boydston (1979).

Although Dewey started his career in the field of psychology while still under the philosophical influence of German idealism, he soon came to know and appreciate the work of the American pragmatists, William James, Charles Peirce and George Herbert Mead, who inspired a social psychology that examined human behaviours. Dewey eventually made his own contributions to American pragmatism by stressing the role that the scientific method could play in improving the human condition, and by openly committing his philosophy to the values and aims of democracy. To Dewey, democracy was less of a political concept than a moral one. When married to a method of enquiry (essentially found in science), democracy represented a moral method of understanding. Dewey, in this sense, became the chief axiologist for American pragmatism, a role that likely led George Herbert Mead to observe that 'in the profoundest sense John Dewey is the philosopher of America' (quoted in Morris 1970:8).

Dewey's social philosophy focused on the worth of the individual in the context of the collective, and aimed to empower the judgements of the common people. Scientific enquiry was favoured because it represented a method of deliberation that provided provisional answers to situational or emergent problems. These emergent problems comprised the main focal points for enquiry. To Dewey, problems were always seen as opportunities for growth and improvement. He believed that by subjecting the problems of the present to a method of enquiry, humanity could reconstruct and improve itself.

Dewey's programme for American pragmatism yoked together science, democracy and education (Dewey 1916). He bridged conserving and transforming agendas by fashioning a method of understanding within a democratic ethic. He argued that education should always be responsive to the organic interplay between the nature of the learner, the values of the society and the world of knowledge embodied in organized subject matter (Tanner and Tanner 1990). Despite a variety of criticisms, some of which was overtly ideological, Dewey continues to attract a diverse scholarly audience.

disability

Despite the fact that between 4 and 5 per cent of the populations of the industrialized nations can be categorized as significantly disabled, disability has been relatively slow to capture the imagination of social scientists. Most research is basically descriptive, tied to agendas of policy formulation and evaluation, advocacy or demographic monitoring.

Disability has become a more visible social phenomenon for four reasons. First, people are living longer, resulting in an increase in age-related physical impairments. Second, advances in medical technology pose ever more difficult questions concerning the survival of babies born with serious impairments. Third, community care policies have rendered people with disabilities socially more visible. Finally, the development of a politicized disability movement means that people with disabilities are resisting their social stigmatization and questioning the social provisions which others make for them.

The most basic question, and perhaps the most controversial, is that of definition. The World Health Organization distinguishes between *impairment,* the absence or defect of a limb, organ or bodily mechanism, *disablement* or *disability,* the reduction or loss of function or ability consequent upon impairment, and *handicap,* the disadvantage or constraint which follows from disability. Social conditions may intervene to make an impairment more or less disabling, while handicap is likely in large part to be due to social factors rather than an inevitable consequence of disability. Handicap can also result from a non-disabling impairment such as disfigurement.

Without denying the 'reality' of impairment, this model has been challenged for placing insufficient emphasis upon the social and cultural construction of disablement. In one view, which dispenses with the category of handicap, disability is wholly the product of social exclusion and marginalization (Oliver 1990). Elsewhere, it is argued that the focus of attention should, for example, be upon disabling built environments and the inadequate nature of the social response to impairments, not upon disabling conditions or people with disabilities (Swain *et al.* 1993).

A number of important themes are clear in the analytical social science literature. Drawing upon the labelling perspective in the sociology of deviance, there is a long-standing interest in how people with disabilities manage and respond to their social stigmatization (Goffman 1963). A more recent concern is with the interaction between the social construction of disability and handicap and stratification, poverty and social closure (Jenkins 1991). This is linked to the question of the social reproduction of disadvantage and disability. Reflecting the new-found voice of the disability movement, perhaps the most significant recent social science development emphasizes the *meaning* of disability for people with disabilities and their experiences and testimony (Ferguson *et al.* 1992). One of the most eloquent contributions to this literature is anthropologist

Robert Murphy's personal account of his own paralysis and gradual assumption of a social identity as disabled (Murphy 1990).

Many questions and issues remain for social science. Two further examples will suffice. First, what in Britain is known as learning difficulties or mental handicap, and in the USA as mental retardation, presents a specific set of difficulties and research questions. For example, community care philosophies as they apply to people with intellectual impairments problematize the cultural construction and imposition of 'normality' (Baldwin and Hattersley 1991; Chappell 1992). In terms of interpretation, how we may best document and understand the social experiences of people with learning difficulties is a question of some methodological and epistemological moment.

Second, the comparative study of disability has been neglected. Our understanding of cross-cultural variation in the interpretation and definition of disability is unsystematic and shallow. Nor is this a matter of purely intellectual interest. For the developing nations, disability is a subject of pressing practical concern (Coleridge 1993). Impairments are caused, *inter alia,* by dietary deficiency, inadequate health care and poor social provision; in turn, disability makes its own contribution to poverty and underdevelopment. In this respect, as in so many others, disability offers challenges to the social sciences which are theoretical, methodological and ethical.

discourse analysis

Discourse analysis refers to a lively but theoretically contested crossroads between several social science disciplines. Here social and cognitive psychologists have come into creative but sometimes rather uncomfortable contact with sociologists, philosophers, rhetoricians, linguists and literary theorists as they rework their theoretical ideas in the terrain of discourse (itself a contested notion). To further the confusion, discourse analysis is sometimes treated as a generic term to refer to virtually all work on language use in its social or cognitive context and at other times as a label for specific bodies of work, or as a contrast to text linguistics or conversation analysis. It is perfectly possible to have two books on discourse analysis which have no overlap in content at all.

At the boundary of cognitive psychology and linguistics there is work done in the tradition of discourse processes. Discourse analysis is here defined as the study of linguistic units that are larger than the sentence, and the hope is that some of the successes of linguistic analysis with smaller units could be repeated in this domain. Work in this tradition considers the way that individual utterances or sentences cohere into spoken or written discourse, and the relation between such patterning and the psychological phenomena involved in representing and comprehending such organizations. For example, it might ask whether there is a regular grammar underlying a written narrative, and it might consider whether the reader is using a cognitive representation such as a script or schema to recover the sense from the narrative.

Another distinctive area of discourse analysis has been developed principally using the example of classroom interaction. Sinclair and Coulthard (1975) attempted to provide a systematic model which would account for some of the typical interaction patterns that take place in teaching in terms of initiation-response-feedback (IRF) structures. For example,

Teacher: What's the capital of Austria? *(Initiation)*
Pupil: Berne, Miss. *(Response)*
Teacher: Close Jenny, have another go. *(Feedback)*

The ambition was to provide a model that would ultimately account for discourse structure in a range of settings such as doctor-patient interactions, news interviews and committee meetings. Despite some success in characterizing features of rather formal kinds of classroom interaction, this model has encountered a series of difficulties which are mainly a consequence of applying a basically linguistic approach to the complex social practices taking place in classrooms and similar locations.

If linguistic forms of analysis take the upper hand in these first two areas, a separate tradition of discourse analysis has been more driven by developments in sociology and literary theory. The ambition here is rather different. Instead of being primarily concerned with extending linguistics, or connecting it to cognition, it is attempting to provide an

alternative way of doing social science which is much more responsive to the idea that talk and writing—whether in an interview, a questionnaire, or an everyday conversation—is oriented to action.

In its simplest form, this tradition started with the observation that, when researching a complex social domain such as science, there are wide variations in the accounts given by different scientists and even by the same scientist in different settings. Rather than treat this as a methodological problem to be resolved by 'triangulation' from the different accounts, or by the use of ethnographically acquired knowledge of the setting, these discourse analysts endorsed the virtue of taking such variation as a research topic in its own right. In an influential study of a group of biochemists, Gilbert and Mulkay (1984) show how they construct versions of their social world using two very different 'interpretative repertoires', or interrelated vocabularies of terms, metaphors and tropes. The 'empiricist repertoire' predominates in research papers and is used by scientists to warrant their own beliefs in the manner of textbook science; the 'contingent repertoire' is a much more fragmentary set of notions which are used in informal settings to explain away beliefs seen as false in terms of social, political and psychological influences. Work of this kind has not only focused attention on the workings of scientists' texts but also raised questions about the literary forms with which social scientists construct and authorize their own versions of reality.

This approach has been reworked by social psychologists who have built a more explicit theoretical grounding which draws upon ideas from both ethnomethodology and post-structuralist thinking (particularly the work of Barthes and of Foucault, who has sometimes been described as a continental discourse analyst). Ironically, this form of discourse analysis has been used to question the status of some of the very cognitive notions which are central to the 'discourse processes' tradition. It has also been used in a critical manner to throw light on ageism, sexism and racism. For example, Wetherell and Potter (1992) mapped the interpretative repertoires that white middle-class New Zealanders used to construct versions of their world in talk and writing which justified inequalities and undermined arguments for social change. A striking conclusion from this study was the way that egalitarian and liberal notions were selectively drawn upon to support racist claims.

Some social scientists have been discomforted by the relativist thrust to this line of discourse analysis. For its proponents it is a way of studying the resources (interpretative repertoires, devices, category systems) that people use for constituting versions of their world, and the practices through which these resources are brought to life.

distribution of incomes and wealth

The distribution of income is usually understood by economists in two main senses: the distribution of income among *factors* (sometimes known as the *functional* distribution of income), and the distribution of income among *persons* (alternatively known as the *size* distribution of income).

The distribution of income among factors is an integral part of the economic analysis of relative prices, output and employment. In this sense there are several theories of income distribution corresponding to different theoretical and ideological stances on these central issues. However, these various analyses usually focus on the same basic economic concepts: employment of the factors of production—land, labour and capital— and the rates of remuneration of their services—rent, wages and profit. This tripartite

classification is by no means the only functional decomposition which is useful in economic theory; in some analyses, for example, a finer subdivision is attempted, distinguishing specifically between interest and profits as rewards to 'waiting' and 'entrepreneurship' respectively, or distinguishing between rewards to different types of labour. In many practical applications the characteristics of national data make it expedient to subdivide the functional categories simply as income from work and income from property. When these categories are applied to the income of an individual, household or subgroup of the population, a third type must be added, transfer income, although items in this category, such as welfare payments and alimony, net out when the economy as a whole is considered. Some macroeconomists gave much attention to the supposed constancy or stability of the share of wages in national income. This interest now appears to have been somewhat misplaced, since it is clear that over long periods this share does change significantly. In many industrialized countries during the twentieth century it has been increasing, and now stands at about three-quarters (UK) to four-fifths (USA).

The distribution of income among persons—the size distribution—and the distribution of wealth may both be thought of as particular applications of a statistical frequency distribution, although they are often represented by other statistical devices such as the Lorenz curve (which in the case of income distribution graphs cumulative proportions of income received against cumulative proportions of income receivers). The frequency distribution of each quantity is generally positively skewed with a long upper tail indicating the presence of relatively small numbers of very well-off people. The dispersion of these frequency distributions, which can be measured in a number of ways, is taken as an indicator of the inequality of the size distributions of income and of wealth.

The size distribution of income is noted almost everywhere for two remarkable qualities: the great inequality of personal incomes that is revealed, and the stability of the distribution over time. This is true even though the exact shape of the size distribution is significantly affected by the particular definition of income one employs (for example whether one includes transfer incomes and incomes received in 'kind' rather than cash, and deducts personal taxes), and the definition of the income-receiving 'unit' (for example whether one looks at the distribution of income among households, or incomes among persons). In the case of the USA, the top one-fifth of income receivers in 1947 received about 45.5 per cent of total personal income before tax and the bottom fifth then received about 3.5 per cent of total income; in 1977 the shares in total personal income of these two groups were about 45 and 4 per cent respectively (although there was some variation in intervening years) (Blinder 1980). While the composition of personal incomes in the lower tail of the distribution has changed substantially as the scope of government transfers has altered, it is still true to say that in most western-style economies the component of personal income that comes from various forms of property is primarily associated with the upper tail of the distribution. In order to understand the size distribution of *incomes* in the upper tail, therefore, it is important to examine the size distribution of wealth.

One of the most difficult problems in analysing the wealth distribution within any community with reasonably extensive holdings of private property is to decide exactly what one means by wealth. This is not a point of semantics, nor is it one of purely arcane,

theoretical interest. While *marketable* wealth—including financial assets such as stocks and cash balances, and physical assets such as land, houses and jewellery—is fairly readily recognizable for what it is, other forms of wealth may also need to be taken into account in estimating the people's effective command over economic resources. These include various pension rights, which represent substantial *future* claims against economic goods (and are thus in that sense substitutes for cash or negotiable securities that have been held as a precaution against old age), but which may have little or no immediate surrender value. As is the case with the size distribution of incomes, estimates of the distribution of wealth are sensitive to assumptions one makes about the definition of wealth itself and the 'units' of population among whom the wealth is distributed. Moreover, parts of the wealth distribution are also very sensitive to different methods of valuing the components of wealth and to short-term changes in the prices of assets. However, it is virtually incontestable that the size distribution of wealth is much more unequal than the size distribution of income. For example, in the UK in 1976 the top 1 per cent of wealth holders possessed at least 14 per cent of personal wealth (this is on the most generous assumptions which include state and occupational pension rights as personal wealth; were these to be excluded the figure would have been 25 per cent), but the top 1 per cent of income recipients received about 5.5 per cent of personal income before tax (3.5 per cent after tax). Furthermore, it is clear that a substantial proportion of this implied inequality in the distribution of wealth is attributable to the effects of inheritance, rather than to the process of wealth accumulation that takes place during the course of people's lives (Harbury and Hitchens 1979).

Finally, if one switches one's attention from the analysis of the size distribution of income (or wealth) within national economies to the size distribution in the world as a whole, not only do the problems of measurement and comparison become much greater, so also does the dispersion. However one resolves the difficult practical questions of defining and quantifying personal or household incomes on this inter-country basis, it is clear that income inequality within national economies is usually much smaller than the income inequality that persists between countries.

divine kingship

It was Frazer (1890) who first perceived that political power in archaic societies was intimately related to ritual functions, to the control which political leaders exercised over nature and, especially, rainfall. The sacred leader had to be put to death when his strength waned, since it was feared that his physical decline would result in a parallel weakening of the cosmic forces mysteriously associated with his person.

Evans-Pritchard denied the ritual character of regicide, seeing in it no more than the disguised expression of political conflict between rival factions. Studies in Africa have shown, however, that the putting to death of the sovereign forms an integral feature of the symbolic complex of sacred kingship (which Frazer called divine kingship).

This mystical institution, which was supposed to assure fecundity and prosperity, is characterized by a set of traits which are constant, though more or less developed in particular instances. The sacred king or chief commits fundamental transgressions: during his investiture he breaks the law of exogamy and commits real or symbolic incest (as among the Kuba, Lunda, Rwanda and Swazi) or even a sort of cannibalism, which consists in eating the flesh of his clan totem (for example, Rukuba). A formidable and august figure, the sacred chief is hedged about by interdictions which regulate his conduct. This extraordinary being is potentially dangerous, and he may himself be contaminated. If he is regarded as an ambiguous creature, outside culture, this is because he has responsibility for the natural order. The Kuba identify their sovereign at once with a good natural spirit and with a powerful sorcerer.

Very often the king's body, isolated from the group, cannot fulfil its magical function when it begins to age. In some cases he must disappear after an arbitrarily fixed period, at least unless a substitute can be sacrificed to regenerate him. This is, for example, the Swazi conception (see Kuper 1947). Every year, during the summer solstice, the naked king, proclaimed 'bull of the nation', is seated on the principal ox of the herd and then thrown to the ground beside another beast, which has been stolen from a commoner, and which is tortured and sacrificed. The Mundang of Chad put their king himself, the master of the rain, to death at the end of a reign which may not exceed ten years (Adler 1982).

Sacred chiefship is based on a radical separation of political power (ritual in essence) and the society over which it is exercised. It is no accident that many African myths represent the founder of the sacred kingship not as a powerful warrior but as a foreign hunter who possesses powerful magic and bears the stigma of his outsider's status (de Heusch, 1972). This symbolic structure, which recurs in the most diverse historical contexts, is not a mystifying ideological representation of the state. One finds the same elements in tiny Rukuba polities no larger than a single village. The sacred chief here is the prisoner of the group which depends on his magical power to guarantee general prosperity. One cannot assume that this is the primitive form of kingship, but many

African examples do show that various state institutions may develop from this representation of power. The state, in so far as it implies the existence of a system of coercion, requires the emergence of magico-religious institutions which do not fall within the domain of the kinship system, and which are in fact capable of breaking the monopoly of kinship institutions in the field of social organization.

division of labour by sex

The sexual division of labour is a basic structural element in human social organization. Interest in this topic began in the nineteenth century, but understanding was clouded by major misconceptions. These concerned the original human division of labour by sex, changes in this division of labour in the course of human evolution, and consequences for the relations between the sexes. A widespread view was that primitive subsistence was based mainly on tasks performed by males; hunting, fishing and herding. Marx and Engels (1947 [1932]), for example, inferred from this premise that masculine economic superiority was the order of nature, with slavery latent in the human family Engels (1972 [1884]) compounded this misconception by assuming relative constancy of the sexual division of labour over time. He attributed a decline in female status to the larger societal division of labour and the rise of private property, with monogamy a corollary of property relations. A different misconception, found in Durkheim (1933 [1893]), is that the original sexual division of labour was minimal. He viewed differentiation between the sexes as increasing with time, moving towards organic solidarity and strong marriage ties.

Bias towards under-reporting women's contribution to subsistence is common across studies of many types of societies. Reporting biases will be reviewed where relevant in discussion of evidence on the following four topics: the original human division of labour; ethnological variability in sexual division of labour; changes in sexual division of labour with societal complexity; and consequences of the sexual division of labour.

First, evidence for the original human division of labour comes from two sources: primate ethology and the ethnology of foragers. Male specialization in hunting is

consistent with the tendency of male terrestrial primates to specialize in defence. The latter specialization gives a selective advantage to larger males. Sexual dimorphism is a consequence of this original division of labour. Humans are alone among the primates in having a marked sexual division of labour in food production and in having food sharing on a regular basis. Early studies of foragers, while noting that men tend to hunt and women to gather, greatly underestimated the importance of female gathering, and in so doing fostered a view of the human family which overemphasizes the dependence of wives on their husbands. Studies of foragers (Lee and DeVore 1968) show that women's gathering often contributes more than half of the subsistence calories.

Second, variability in sexual division of labour is also much greater than commonly assumed for both pre-industrial and industrial societies. The rise of cross-cultural and cross-national research makes it possible to estimate the relative frequencies of allocations of male and female effort to various tasks. As a result of Murdock's work (Murdock 1937; Murdock and Provost 1973) we now have cross-cultural codes on sexual division of labour for fifty tasks. These codes confirm earlier generalizations about near-universals. Tasks done by males in more than 95 per cent of the sample societies include hunting large land animals, metal-working, wood- and bone-working, boatbuilding, and trapping. Tasks done by females in more than 95 per cent of the sample include only cooking and care of infants. Patterns of sexual division of labour appear to have only a partial basis in biology, and most tasks exhibit high variability. This is especially true of the important food production tasks pertaining to agriculture and the care of domesticated animals.

These variations, however, fall within constraints of a relative rather than universal nature. Many researchers have sought rules of consistency in the variable allocation of tasks. While earlier researchers emphasized the male strength advantage, research in the 1970s placed more emphasis on constraints due to the reproductive specialization of women. Brown (1970) emphasized the compatibility of women's tasks with simultaneous child-care responsibilities. Women's tasks are likely to be relatively close to home not dangerous, and interruptible. Burton *et al.* (1977) proposed that these relative constraints produce entailments within production sequences. Women tend to take on additional tasks within production sequences in an order which begins with tasks closer to the home and ends with tasks farther afield. Men take on additional tasks in the opposite order, from the more distant to those closer to home. Burton and colleagues found entailment chains for the following production sequences: animal tending, animal products, textiles, fishing and agriculture. An example from agriculture: if women clear the land, they also prepare the soil; if the latter, they also plant, tend crops, and harvest. If they tend crops, they also fetch water, and if they plant, they also prepare vegetables for cooking.

Third, in pre-industrial societies female participation in many tasks declines with societal complexity. For example, women build houses in nomadic societies but not in sedentary societies; and female participation in pottery-making declines with increasing population density. For crafts, the explanation for these changes seems to be the evolution of occupational specialization, which displaces craft activity from the domestic arena to the workshop. Agricultural intensification is accompanied by dramatic decreases in female contributions to farming. For Boserup (1970) agricultural intensification results from population pressure and introduction of the plough, and pulls men into agriculture to

meet the increased demand for labour. Ember (1983) suggested a second mechanism in the shift to male farming: women are pulled out of farming into the household economy by increased time spent on food processing, household chores, and child care. Burton and White (1984) carried this work further with a model of four factors—population density, a short growing season, presence of the plough, and high dependence on domesticated animals—which lead to the displacement of women's labour from agriculture to the domestic and less economically visible activities.

The four-factor intensification model accounts for many empirical observations concerning female subsistence participation: that it is higher in tropical climates and in horticultural societies and that it is higher with root crops than with cereal crops, for these attributes are correlated with a long rainy season, low dependence on domesticated animals, absence of the plough, and low population density.

Finally, several researchers following Boserup (1970) hypothesized that agricultural intensification has a negative impact on female control of economic resources. This research suggests that high female subsistence contributions are a necessary prerequisite to female control of economic resources, and to women's freedom of choice in life events. In searching for other consequences of the sexual division of labour, Heath (1958) and several other researchers found that low female subsistence contributions lead to monogamy. Such studies shed light on puzzles such as the rise of monogamy and decline in women's status, originally noted by nineteenth-century theorists.

divorce

Divorce is the legal procedure by which marriage can be formally ended. Not all societies permit divorce (e.g. the Republic of Ireland) but in the majority of western countries, not only is divorce now possible but also legal constraints and obstacles to divorce have been gradually reduced since the end of the Second World War. It is usually possible to divorce on the grounds of incompatibility, and it is no longer necessary to prove that a spouse has committed a matrimonial offence such as adultery or desertion. The fact that divorce is now easier to obtain has, however, led to a belief that divorce itself is easy. Moreover, the idea that couples divorce simply because they are incompatible masks the seriousness of problems that may exist within the institution of marriage. Such problems may include violence, economic deprivation and cruelty to children. It is a mistake to imagine that couples divorce readily for whimsical reasons.

In the European Union, Denmark had the highest rate of divorce in 1990 (12.8 divorces per 1,000 existing marriages) with the United Kingdom close behind (12.6 per 1,000). The USA has the highest divorce rate of all developed societies and some statistics suggest that one in two marriages will end in divorce. It is necessary to be cautious about such statistics and it is particularly difficult to compare trends across countries. It would, for example, be wrong to presume that marriages do not break down in some countries where legal divorce is not available or where it is restricted. Couples in Catholic countries, for example, may rely on the process of annulment or may simply separate without going through any legal or formal process.

The rise in divorce in the west, particularly immediately following the Second World War, led to concerns over declining moral standards and fears about the stability of society. Rising divorce rates have often been (popularly) associated with rising rates of illegitimacy and of delinquency; such trends can be seen as generating moral panics and tendencies to blame individuals rather than understanding the deeper structural changes which may be giving rise to such developments. These sorts of moral concerns continue in the 1990s but they have been largely overtaken by two questions of social policy: first, the relationship between divorce and poverty, especially for women and children; and second, concern over the welfare of children who have experienced their parents' divorce.

It has become clear that divorce causes poverty because, at the very least, the same resources have to spread across two households (Eekelaar and Maclean 1986; Weitzman 1985). This problem is exacerbated if the main wage-earner re-partners and has additional children. Evidence suggests that the resulting hardship is most acutely felt by divorced mothers who typically retain the care of children. This is because they may not

be able to return to the labour market or because they can do so only a part-time basis, often returning to lower status, more poorly paid jobs than those they held before their marriage. Such women tend to become reliant on low levels of state support, or on inadequate wages. In addition, in countries where health care is based on private insurance, divorced women often find they lose access to decent health care provision because it is typically attached to a husband's employment and/or record of contributions. On divorce a wife can no longer claim on such schemes because she is no longer next of kin or family member, and it is unlikely that she will have sufficient contributions of her own to generate sufficient cover. Divorced wives also lose entitlement to their husbands' occupational pension schemes and so, later in life, they are forced to become reliant on low state provisions or their own partial contributions. Thus divorce 'stores up' long-term poverty for many women if they have left the labour market to care for children and if they do not remarry (Glendinning 1992; Maclean 1991).

On the issue of children's welfare, the main concerns relate to the effects of poverty and the effects of emotional disturbance on children. It is not easy to disentangle these two issues because typically children experience the loss of a parent (usually a father) at the same time as facing a significant decline in living standards. But research on the impact of divorce on children is quite contradictory with some claiming that divorce *per se* has little impact and others suggesting that it is very harmful. There has been an interesting shift in research focus since the 1960s and 1970s. In these decades the focus was on the potential harms of maternal deprivation. This research was often used to blame working mothers for producing delinquent children. In the 1990s, however, the focus became the absent father. It is now his loss which has become associated with disturbed or antisocial behaviour. As a consequence many countries in the European Union, the USA, Australia and New Zealand are now developing divorce laws which try to encourage fathers to remain in contact with children after divorce. Equally many are striving harder to make fathers pay more realistic amounts towards childrearing costs (for example the Child Support Act 1991 in England and Wales). Such policies *could* shift the economic burden of divorce on to men and away from women, but the complexities of many benefit systems and the difficulties involved in this redistribution may produce conflicting outcomes in which women and children do not necessarily benefit. It is clear, however, that many national governments wish increasingly to avoid paying for the economic costs of divorce through systems of state benefits. It remains to be seen what the consequence will be of these new strategies to deal with divorce.

domestic violence

There have been three historical periods during which the problem of domestic violence has become a public issue and been responded to by reformers and agencies of the state—1870s, 1910s and 1970s to present. At each of these junctures, the problem was publicly recognized, statistics were gathered, explanations were proffered and policy reforms were introduced. On each occasion, the move to public recognition and reform was led by a vigorous women's movement.

The issue has been variously described as wife-beating and, more recently, as violence against women, woman abuse or domestic violence. Research findings show that across time and across cultures violence in marital and marital-like relationships is overwhelmingly asymmetrical, with men using violence against their female partners. While much of this violence remains unreported, current findings from crime statistics, victim surveys and depth-interviews reveal that between 10 and 25 per cent of all 'married' women have experienced violence from their male partner at some time during their life. The nature of the violence ranges from slapping and shoving to domestic homicide. The most common form is punching and kicking resulting in injuries such as bruising, broken bones and teeth, and cuts. Evidence further suggests that this physical violence is usually accompanied by other acts of aggression, coercion and intimidation, and is sometimes associated with sexual violence.

Across societies, homicide in domestic settings is, for the most part, the killing of wives, uxoricide. This usually occurs in the context of a history of sustained violence by the man against his female partner. Occasionally women kill husbands and the rate of these acts varies across societies, but this usually occurs in the context of a history of male violence directed at the woman. While death is an unusual outcome of domestic assaults, it none the less represents an important proportion of all the homicides of women, and in some countries uxoricide accounts for a considerable proportion of all the homicides. The evidence about domestic violence tells a common story, of a problem that is serious and widespread in most societies and of violence perpetrated by males against females.

Various explanations have been proposed by social scientists to account for this violence: social and individual pathologies; interactional, situational and family

dynamics; and institutional, cultural and ideological forces. In many of these perspectives, male power, domination and control are emphasized to varying degrees. Historical, anthropological and contemporary research consistently reveal that conflicts associated with the use of violence typically include male concerns about power and authority, about jealousy and sexual possessiveness and about the domestic labour of women (e.g. food preparation and child-care). Individual backgrounds and learning experiences have also been shown to be important.

Domestic violence is a problem that has simultaneously involved researchers, social activists and policy makers. Activists have introduced the problem into the public agenda, secured its definition as a social problem and engaged the state in the process of policy making. Researchers have added systematic knowledge and policy makers have engaged in efforts to respond with measures intended to reduce or eliminate the problem and/or to provide support to its victims. The women's movement has been at the forefront in recognizing the problem internationally, providing the major response in the form of refuge or shelter for abused women and their children, and engaging the state in seeking reforms.

In addition to studying the nature of violence, social scientists have investigated the responses of the state, including their shortcomings and the effectiveness of existing responses and innovative policies and programmes. In this respect, initial attention was focused primarily on housing and refuge provision for abused women and criminal justice responses to violent men and the women they victimized. Evidence shows that housing and shelter provide important sanctuaries for women and children; traditional justice responses are not usually effective in reducing violence or supporting victims; and there is now a climate of change in law and law enforcement in some countries. An emerging area of research focuses on the effectiveness of innovative legal responses to violent men. Studies of the social services show a similar history of ineffective responses followed by innovations whose effectiveness is yet to be studied. Health and health care services have become the focus of growing academic and policy attention.

Within the social sciences, the disciplines of sociology, criminology and psychology have to date provided the greatest amount of research and scholarship. Anthropology, evolutionary psychology, medicine and nursing have begun to study the problem to add new explanations and enhance, modify or challenge existing ones.

dreams

Despite their power to bewilder, frighten or amuse us, dreams remain an area of human behaviour little understood and typically ignored in models of cognition. As the methods of introspection were replaced with more self-consciously objective methods in the social sciences of the 1930s and 1940s, dream studies dropped out of the scientific literature. Dreams were not directly observable by an experimenter and subjects' dream reports were not reliable, being prey to the familiar problems of distortion due to delayed recall, if they were recalled at all. More often dreams are, of course, forgotten entirely perhaps due to their prohibited character (Freud, 1955 [1900]). Altogether, these problems seemed to put them beyond the realm of science.

The discovery that dreams take place primarily during a distinctive electrophysiological state of sleep, rapid eye movement (REM) sleep, which can be identified by objective criteria, led to a rebirth of interest in this phenomenon. When REM sleep episodes were timed for their duration and subjects woken to make reports before major editing or forgetting could take place, it was determined that subjects accurately matched the length of time they judged the dream narrative to be ongoing to the length of REM sleep that preceded the awakening. This close correlation of REM sleep and dream experience was the basis of the first series of reports describing the nature of dreaming: that it is a regular nightly, rather than occasional, phenomenon, and a high-frequency activity within each sleep period occurring at predictable intervals of approximately every 60 to 90 minutes in all humans throughout the life-span. REM sleep episodes and the dreams that accompany them lengthen progressively across the night, with the first episode being shortest, of approximately 10–12 minutes duration, and the second and third episodes increasing to 15–20 minutes. Dreams at the end of the night may last as long as 45 minutes, although these may be experienced as several distinct

stories due to momentary arousals interrupting sleep as the night ends. Dream reports can be retrieved from normal subjects on 50 per cent of the occasions when an awakening is made prior to the end of the first REM period. This rate of retrieval is increased to about 99 per cent when awakenings are made from the last REM period of the night. This increase in ability to recall appears to be related to an intensification across the night in the vividness of dream imagery, colours and emotions. The dream story itself in the last REM period is furthest from reality, containing more bizarre elements, and it is these properties, coupled with the increased likelihood of spontaneous arousals allowing waking review to take place, that heighten the chance of recall of the last dream. The distinctive properties of this dream also contribute to the reputation of dreams being 'crazy'. Reports from earlier dreams of the night, being more realistic, are often mistaken for waking thoughts.

Systematic content analysis studies have established that there are within-subject differences between dreams collected from home versus laboratory sleep periods, with home dreams being on the whole more affect-laden. This calls into question the representativeness of laboratory-collected dreams, particularly when subjects have not been adapted to the laboratory and the collections are carried out only for a limited period. More often, between-group comparisons are being made. Here clear differences have been reported between the home-recalled dreams of males and females, old and young, rich and poor, and between those of different ethnic groups living in the same geographical area. These differences reflect the waking sex-role characteristics, personality traits, and sociocultural values and concerns of these groups. These findings raise the question of whether dreams make some unique contribution to the total psychic economy, or merely reflect, in their distinctive imagistic, condensed language and more primitive logic, the same mental content available during wakefulness by direct observation or interviewing techniques.

The question of uniqueness of dream data and function may well be answered differently for home and laboratory retrieved dreams. Home dreams are so highly selected, whether from dream diaries or those recalled in response to questionnaires, that they yield culturally common material much like the study of common myths. In the laboratory, where the database includes all of the dreams of a night in sequence and where experimental controls can be instituted to ensure uniform collection, the yield is more individual and varied. Despite this, the question of dream function has continued to be an area of controversy in modern sleep research since the mid-1950s. It has been approached empirically through studies of the effects of dream deprivation with little progress. Neither awakenings at REM onset to abort dreams nor nights of drug-induced REM sleep deprivation have been followed by reliable deficits in waking behaviour or the appearance of dream-like waking hallucinations.

It is possible that these studies have not been carried out long enough or that the dependent measures have not been appropriately designed. Other studies have proceeded by manipulating the pre-sleep state to heighten a specific drive, such as thirst or sex, or to introduce a problem requiring completion such as a memory task and testing for the effects on dream content or subsequent waking behaviour. Again, effects have been small and rarely replicable. The laboratory setting and experimenter effects have been implicated in masking the very phenomenon the studies were designed to reveal, being

more powerful stimuli than the experimental manipulation itself (Cartwright and Kaszniak 1978).

Seldom have theoretical models of dream function been tested. These have varied widely in the psychological processes implicated. Learning and memory have been prominent, as in the Hughlings Jackson (1932) view that sleep serves to sweep away unnecessary memories and connections from the day. This has been revised by Crick and Mitchison (1983) and stated as a theory that dream sleep is a period of reversed learning. However, the opposite view that dreaming has an information-handling, memory-consolidating function (Hennevin and Leconte 1971) is also common. Other writers stress an affective function. Greenberg and Pearlman (1974) and Dewan (1970) hold that during dreaming, reprogramming of emotional experiences occurs, integrating new experiences and updating existing programmes. The modern psychoanalytically oriented view is an adaptation of Freud's conception of dreams as safe ways for unconscious drive discharge to take place (Fisher 1965; French and Fromm 1964). Beyond the issue of what psychological process is involved is the further problem posed by those who deny that studies of dream content can make any headway without taking into account their latent as well as their manifest content. This requires obtaining waking associations to each dream to plumb their function fully. Such a design would produce confounding effects on subsequent dreams.

Despite the theoretical morass and methodological problems rife in this field, systematic headway in understanding dreams has been made. One such advance came from a ground-breaking longitudinal collection of home and laboratory dreams of boys and girls by Foulkes (1982). These were analysed to explore the age-and sex-related changes in dream structure and content in terms of the cognitive and other aspects of the developmental stages of these children. Another advance came in the area of methodology with the development of standardized content analysis systems (Foulkes 1978) and rating scales (Winget and Kramer 1979). Another improvement in design combines the advantages of the methods of the laboratory with the reality of a field study by predicting dream-content differences in the laboratory retrieved dreams among groups of persons differing in response to a major affect-inducing life event. For example, Cartwright (1991) has shown that those who dream directly of the emotionally disturbing person (the former spouse in a divorcing sample) more often made a good waking adjustment to the change.

The study of dreams is ready to move beyond the descriptive. Many factors have been amassed about this distinctive mental activity, without any clear understanding of its basic nature. Many points of view on dream function still compete (see Moffitt *et al.* 1993). How is a dream put together into a dramatic format without the contribution of any voluntary intent of the dreamer? How are the new perceptions formed that often express in such highly economical terms a coming together of old memories and current waking experiences? Do dreams have effects despite the fact that they are forgotten? What do these processes tell us about how the mind works? Dreams are a difficult challenge. They deserve our best response.

drug use

The concept 'drug' is both socially constructed and concretely real. That is, first, what a drug is depends on the perspective of the definer; certain definitions are relevant only within specific social contexts. Second, once drugs are defined in a certain fashion, their concrete reality is no longer a matter of definition but of empirical fact, subject, of course, to the usual scientific debate and confirmation. Put another way, drugs are physical entities with concrete properties and objective, measurable effects, but the

properties and effects may or may not be relevant, according to the observer's definitional and conceptual framework.

Of all definitions of drugs, the one most widely accepted in the social sciences is substances that are *psychoactive,* or influence the mind in significant ways. Among other things, drugs influence how the human mind works, they have an impact on mood, emotion, feeling, perception, and thinking processes. This definition excludes substances used within a medical context, such as penicillin and antibiotics, which are not psychoactive. This definition includes those substances that strongly influence the mind but which are legally obtainable and, as a result, may not be widely regarded as drugs by the general public, such as alcohol and tobacco cigarettes.

The ingestion of mind-altering substances is very nearly a human universal; in practically every society on earth, a sizeable proportion of its members take at least one drug for psychoactive purposes. This has been true for a significant stretch of human history. Fermentation is one of the earliest of human discoveries, predating even the fashioning of metals; humans have been ingesting alcoholic beverages for at least 10,000 years. Strands of the marijuana plant embedded in Chinese pottery have been found by archaeologists in sites estimated to date back some ten millennia (Abel 1980). Dozens of plants containing chemicals that influence the workings of the mind have been smoked, chewed, or sniffed by members of societies all over the world: coca leaves, the opium poppy, marijuana, psilocybin (or the 'magic' mushroom), *Amanita muscaria,* the peyote cactus, quat leaves, nutmeg, coffee beans, the yagé vine, and tea leaves. During the past century or so, hundreds of thousands of psychoactive chemicals have been discovered, isolated or synthesized by scientists, physicians or technicians. Thousands have been marketed for medicinal purposes. According to the journal, *Pharmacy Times,* roughly 1.5 billion prescriptions for drugs are written each year in the USA alone, roughly one in six or one in seven of which are psychoactive. In the USA, roughly two-thirds of the population age 12 and older has drunk alcohol one or more times in their lives, and half the population has done so during the past month; one-quarter of all Americans are current smokers of tobacco cigarettes; one-third has at least tried marijuana, 10 per cent have used it in the past year, and 5 per cent have done so in the past month (Goode 1993). Drug-taking is a widespread and extremely commonly indulged-in activity.

Most of the time that psychoactive chemicals are ingested, they are used 'in a culturally approved manner' (Edgerton 1976), with little or no negative impact on the user or on society. However, in a significant number of cases, drugs are taken in a culturally unacceptable or disapproved fashion: a condemned drug is taken instead of an approved one, it is taken too frequently or under the wrong circumstances, for the wrong reasons, or with undesirable consequences. With the establishment of the modern nation-state and, along with it, the elaboration of an explicit legal code, certain actions came to be judged illegal or criminal. The use, possession or sale of certain drugs, taking drugs in certain contexts, or the ingestion of drugs for disapproved motives, have been regarded as crimes in nearly all countries, punishable with a fine or imprisonment of the offender.

The catch-all term drug 'abuse' has been used variously by different observers. Some experts argue that drug abuse should be defined by its *illegal* and *extra-medical* character (Abadinsky 1989), a definition which would exclude the excessive and abusive consumption of alcohol. Others specify that drug 'abuse' must be defined by the

deleterious effects that users and others suffer as a consequence of the use of psychoactive chemicals (White 1991). The controversy underlines the socially constructed character of drugs and their use.

It must be emphasized that drug use is not a unitary phenomenon. There exist, to begin with, different types of drugs, classified according to their action. Drugs are commonly categorized on the basis of their impact on the central nervous system (CNS), that is, the brain and the spinal column. Some drugs speed up signals passing through the CNS; pharmacologists refer to them as *stimulants.* Stimulants include cocaine, the amphetamines and caffeine. Nicotine, the principal psychoactive ingredient in tobacco cigarettes, also has a simulating effect, but some of its other effects are sufficiently distinct as to merit a separate classification. Other drugs retard, slow down, or depress signals passing through the CNS, and are referred to as *depressants.* The two major types of depressants include *narcotics* or *narcotic analgesics* (such as opium, morphine, heroin and methadone), which dull the sensation of pain, and sedatives or 'general depressants' (such as alcohol, barbiturates, methaqualone and Valium), which are anti-anxiety agents. Most psychoactive drugs are not classifiable by the stimulant-depression continuum. A wide and miscellaneous range of psychoactive substances are used to treat mental disorder or mental illness; the two major types are the *antipsychotics* (or phenothiazines), which are administered to schizophrenics, and *antidepressants* (or mood elevators), which are administered to the clinically depressed. Hallucinogens or 'psychedelics' are capable of producing dramatic perceptual changes (although they very rarely produce genuine hallucinations); examples include LSD, mescaline and psilocybin. The cannabis products, marijuana and hashish, are usually thought to occupy a separate and distinct category of psychoactive substances.

Even the same psychoactive substance may be taken by different individuals for different motives, to achieve different goals. Indeed, even the same individual may take the same drug at different times for different purposes. Attaining religious or mystical insight or ecstasy, healing the mind or body, suppressing fatigue, hunger or anxiety, enhancing pleasure or hedonism, facilitating interpersonal intimacy, following the dictates of a particular group or social circle, and establishing an identity as a certain kind of person include some of the more commonly expressed motives for psychoactive drug use. A drug's psychoactive properties may be central to the user's motive for taking it, or they may be incidental; the intoxication or 'high' may be experienced for intrinsic reasons, that is, as an end in itself, or the drug may be taken for instrumental purposes, that is, to attain a specific and separate goal, such as alleviating pain. Of the many varieties of drug use, perhaps the three most common and important are legal recreational use, illegal recreational use, and legal instrumental use, mainly medical. Each of these modes attract strikingly different users and have strikingly different consequences. It is a fallacy to assume that the pharmacological properties of a drug dictate the consequences of its use; factors such as motives for use, the social context in which use is embedded, the social norms surrounding use, methods of use or 'route of administration,' all play a role in influencing the impact of the use of psychoactive substances.

First, *legal recreational use* refers to the use of a psychoactive drug, whose possession and sale are not against the law, for pleasurable purposes. In western nations, this refers mainly to alcohol consumption. Although, in the USA, there has been an effort to

redefine alcohol as a drug in the educational curricula, even today, much of the public does not see alcohol as a drug. When this term is used to apply to substances consumed outside a medical context, it typically connotes those whose possession has been criminalized and whose use is condemned. However, in the pharmacological sense, that is, in terms of its effects, alcohol is psychoactive, it is used for this purpose, it can produce a physical dependence or addiction, in heavy, long-term, chronic users, and it causes or is associated with a wide range of medical maladies. Many estimates place the proportion of alcoholics at roughly one drinker in ten, and argue that alcoholism is the west's most serious drug problem. In short, alcohol 'is a drug by any other name'.

Second, of all types of drug use, *illegal recreational use* has attracted the most attention and interest. In the generation following the early 1960s, western Europe and North America experienced an unprecedented rise in the recreational use of illegal psychoactive drugs. The most widely used of these are the cannabis products, marijuana and hashish. In a number of western countries, there are as many episodes of cannabis use as episodes of all other illegal drugs combined. Of all illegal drugs, cannabis is the one that users are most likely to 'stick with' or continue using regularly, and least likely to abandon or use only episodically. In other words, among illegal drugs, marijuana has the highest continuance rate. At the same time, as a general rule, legal drugs such as alcohol and cigarettes have far higher continuance rates than illegal drugs, marijuana included (Sandwijk *et al.* 1991). Hallucinogens, such as LSD, tend to be taken on an experimental or episodic basis, and are extremely rarely taken heavily or abusively. As with alcohol, the vast majority of cannabis users take the drug on a moderate, controlled fashion. Still, some illegal drugs do attract heavy, chronic, abusive users. In the USA the number of heroin addicts has been estimated at half a million; in the UK, the number of registered addicts has increased tenfold since the mid-1980s. It has been estimated that there are several million daily cocaine users in the USA. However, for all illegal substances, the vast majority of at-least one-time user or triers either abandon the drug after a few experimental trials or use it moderately, in a controlled fashion, on a once-in-a-while basis (Zinberg 1984).

Third, the *legal instrumental or medical use* of psychoactive drugs in the western world has undergone dramatic changes over the course of the twentieth century. At the turn of the nineteenth century, preparations containing psychoactive substances such as morphine and cocaine were freely available and were widely used to cure or treat medical and psychiatric ailments. Legal controls on the sale of these nostrums, or even what they contained, were practically nonexistent (Berridge and Edwards 1987; Musto 1987). In contrast, the twentieth century has witnessed an avalanche of legal controls on psychoactive substances for medical purposes. In western countries, the primary mode of dispensing drugs is via medical prescription. In the USA, the number of prescriptions written for psychoactive drugs rose steadily until the early 1970s, when misuse and abuse of these substances was widely publicized. Since that time, there has been a steep decline in the number of prescriptions written for psychoactive drugs. (In contrast, the number of prescriptions written for non-psychoactive drugs has remained stable, or even risen somewhat, because the west has an ageing population.) Between 1970 and the 1990s, prescriptions for the amphetamines generally and the barbiturates have declined 90 per cent; Valium, once the USA's best-selling prescription drug, has dropped to 47th place;

and some drugs, such as methaqualonc, a sedative, and Benzedrine, an amphetamine, are no longer obtainable via prescription (Goode 1993). The sales of a small number of recently introduced psychoactive drugs—such as Prozac, an antidepressant, and Xanax, a sedative—have boomed largely because they have been perceived as safer and/or more effective alternatives to previously popular prescription drugs. As a general rule, the overall decline in the prescription use of psychoactive pharmaceuticals has produced a decline in recreational 'street' usage; this has been the case, most dramatically, for amphetamine, barbiturate and methaqualone use.

In the 1950s, it was discovered that the phenothiazine drugs suppress the symptoms of mental disorder, especially schizophrenia. Since that time, the administration of antipsychotic drugs, such as Thorazine, Stelazine and Mellaril, to mental patients has been increasing dramatically. There were just under 560,000 resident patients in publicly funded mental hospitals in the USA in 1955; in the mid-1990s there are a shade over 100,000. Some three-quarters of all individuals diagnosed as mentally disordered are taking phenothiazine drugs on an outpatient basis. While the number of admissions to mental hospitals more than doubled between the 1950s and the 1990s, the length of stay of mental patients then was six to eight months; currently it is two weeks (Ray and Ksir 1993). Mentally disordered individuals who once would have been confined to mental institutions are now outpatients.

Since the mid-1980s in the USA, there has been a growing call for the full legalization or decriminalization of all currently illegal psychoactive substances, including cocaine and heroin. The pro-legalization argument is based on three assumptions: first, that use and abuse will not increase when legal controls are removed; second, that the currently illegal drugs are not as harmful as those that are legal, nor as harmful as legislators and the public believe; and third, that criminalization is both ineffective and counter-productive (Nadelmann 1989).

The vast majority of the American public is strongly opposed to full legalization, however, and legislators, even were they convinced of the proposal's feasibility, would be voted out of office were they to support it. Moreover, the assumption of no increase in use or abuse is not entirely convincing, for seven main reasons. First, there is a strong correlation between cost and use, and it is criminalization that keeps the cost of illegal drugs high. Second, if we take them both at their word and their actions, current abusers and heavy users would use substantially *more* were their substances of choice readily available. Third, in social contexts where psychoactive substances are or were readily available, such as among physicians and other medical workers, and among military personnel during the Vietnam War, use has been high. Fourth, during the period of national alcohol Prohibition in the USA, the consumption of alcohol did decline (Lender and Martin 1987). Fifth, where risk-taking activities remain beyond the reach of the law, a certain proportion of individuals will engage in them—motorcyclists refusing to wear helmets, motorists not wearing seat belts—while, when those same activities are legally controlled, a much lower proportion do so. Sixth, as we saw, continuance rates for the legal drugs are significantly higher than they are for the illegal drugs. Finally, in the USA, outlawing the sale of alcohol to persons under the age of 21 has been accompanied by a significant decline in the number of alcohol-related automobile fatalities in this age group.

It is possible that, while criminalization has produced higher rates of drug-related crime, disease and violence, it has also resulted in lower levels of use than would otherwise have been the case. In other words, as measured by the criterion of *containment,* legal controls may have been successful. Perhaps a 'third path' located somewhere between the current punitive policy and full legalization would be most effective. The Dutch policy of flexible enforcement, *de facto* decriminalization for the 'soft' cannabis products, and harm reduction might be explored by other western countries, including the USA.

DSM-IV

DSM-IV is the fourth edition of the American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders (published in 1994). The DSM-IV is a categorical classification which groups mental disorders based on primarily phenomenological features which are organized into specifically defined sets of criteria. Although developed primarily for its utility in clinical practice, the DSM-IV is also used in training, research, and medical record keeping.

Attempts to classify mental illness date back thousands of years (e.g. Egyptian and Sumerian references to senile dementia, melancholia, and hysteria date back to 3000 BC), and a variety of approaches has been applied. While some systems were based on a large number of narrowly defined conditions, others were established on more inclusive, broad conceptualizations. Classification systems have also differed in the extent to which classification of disorders should be based on aetiology, the course of the illness, or the descriptive presentation of symptom patterns. In the later half of the nineteenth century, Emil Kraepelin developed a classification which combined aspects of various systems: he studied groups of patients whose disorders had the same course, in order to determine their shared clinical symptomotology. Kraepelin's (1917) general methodology has been largely retained in the development of the current DSM system.

Other classification systems were developed in the USA prior to the publication of the DSM-I in 1952; however, the DSM system was the first to emphasize clinical utility. DSM-I was a variant of the World Health Organization's (1948) *International Classification of Diseases, Injuries, and Causes of Death,* 6th edn (later editions are entitled *International Classification of Disease* (IGD)), which was the first edition of the ICD to include a section on mental disorders. The relationship with the ICD system has continued; revisions were closely timed and recent efforts have ensured a greater compatibility between the two systems. The DSM-III (published in 1979) represented a major shift in the approach to psychiatric diagnosis and for the first time included explicit criteria (rather than glossary definitions), multiaxial assessment, and a descriptive approach that was neutral with regard to aetiology. The major innovation of the DSM-IV lies in its documentation and explicit reliance on empirical data in the revision process, the inclusion of over one thousand health and mental professionals in the development of the manual, expanded text sections describing symptom presentations that may vary according to age, gender and cultural differences, and the inclusion of more specifiers, subtypes and course modifiers. A three-step process was utilized in the development of the DSM-IV: comprehensive literature reviews, data reanalyses and focused field trials.

The DSM-IV disorders are grouped into sixteen major diagnostic classes, beginning with mental disorders Usually First Diagnosed in Infancy, Childhood, or Adolescence. Although almost all disorders in the DSM are neutral in regard to aetiology, the next three sections of the manual—Delirium, Dementia, Amnestic, and Other Cognitive Disorders; Mental Disorders Due to a General Medical Condition; and Substance-Related

Disorders—are by definition based on aetiology and are listed before the remaining disorders because of their importance in differential diagnosis. These disorders were formerly referred to as Organic Disorders. The term organic has been eliminated from the DSM because of the erroneous implication that all other disorders in the system have no organic basis. The remaining disorders (except for Adjustment Disorders, which vary in their presentation, but are reactions to stressful events) are grouped based on common presenting symptoms. They are Schizo-phrenia and Other Psychotic Disorders; Mood Dis-orders; Anxiety Disorders; Somatoform Disorders; Factitious Disorders; Dissociative Disorders; Sexual and Gender Identity Disorders; Eating Disorders; Sleep Disorders; Impulse-Control Disorders Not Elsewhere Classified; Adjustment Disorders; and Personality Disorders. An additional section describes conditions which may be a focus of clinical attention (e.g. bereavement, relational problems) but which are not considered mental disorders.

In addition to the criteria set for each disorder, explanatory text describes diagnostic features (e.g. examples of criteria); subtypes and specifiers; recording procedures; commonly associated features and disorders; specific culture, age and gender features; prevalence rates; typical lifetime pattern and evolution of the disorder; familial pattern; and differential diagnosis pointers.

DSM-IV utilizes multi-axial assessment to ensure a comprehensive assessment of the individual's health, environment and functional level. Axis I includes all mental disorders except Mental Retardation and the Personality Disorders, which are listed on Axis II. General Medical Conditions (i.e. any condition listed in the ICD outside of the mental disorders section) are listed on Axis III. Psychosocial and environmental stressors (e.g. occupational or economic problems) are listed on Axis IV, while Axis V is used to record a Global Assessment of Functioning score (i.e. the clinician's assessment of the individual's level of occupational, social and psychosocial functioning; this information is helpful in planning a treatment regimen and in predicting likely treatment outcome).

Numeric codes for each disorder or condition listed in the manual are provided, and are derived from those used in the ICD, 9th edn, Clinical Modification, the official coding system in the USA (US Government Department of Health and Human Services 1979). An appendix lists all disorders with the *International Statistical Classification of Diseases and Related Health Problems,* 10th edn (ICD-10) codes as well (World Health Organization 1992). The ICD-10 is used in most other countries. Thus, the complete compatibility of DSM-IV with both systems facilitates medical record keeping and statistical comparison both in the United States and internationally.

Several caveats in the use of the DSM-IV are noted. First, although the inclusion of specific criteria sets aids in the diagnosis of mental disorders, the criteria are provided as guidelines and require specialized clinical training in their application. Also, additional information beyond that needed to make a diagnosis is necessary in the formulation of an appropriate treatment plan. Special consideration should be given when the clinician is unfamiliar with the cultural reference of the individual that he or she is evaluating; a clinician may mistake thoughts or actions that are an accepted and typical part of that person's culture as symptoms of a mental disorder.

The manual is intended to be comprehensive and reflect current knowledge but may not include all conditions for which individuals seek treatment, or for which research may

be appropriate. Inclusion in the manual of a mental disorder does not imply that the condition meets legal or other non-medical criteria for what constitutes disability, mental disease, or a mental disorder. Clinical diagnosis in itself does not have a one-to-one relationship with issues of control, competence, criminal responsibility, disability or impairment.

dual economy

The term dual economy has at once a technical academic meaning and a broader, more general meaning. In the former sense it relates to the simultaneous coexistence within the same economy of two different sectors, divided by different culture, different laws of development, different technology, different demand patterns, and so on. In certain models or theories of development, such as two-sector division, and the interaction between the two sectors, that is, a dual economy is taken as a foundation for theoretical analysis.

The best known of such models is the Arthur Lewis model, based on his famous article 'Economic development with unlimited supply of labour' (1954). Lewis distinguishes between a rural low-income subsistence type sector in which there is surplus population

(zero or very low marginal productivity of labour), and a developing urban capitalist sector in which wages are held down by the pressure of rural surplus population with resulting rapid development, ultimately exhausting the labour surplus. A considerable literature has followed in the wake of the Lewis model. The main modification of this model has been through Harris and Todaro (1970), who pointed out that the transfer of the labour surplus from rural to urban sectors could lead to urban unemployment and the development of an urban 'informal sector' rather than a reduction in wages in the capitalist sector to subsistence level.

The concept of the dual economy was originally developed by Boeke (1953), to describe the coexistence of modern and traditional sectors in a colonial economy. The term dual (or more frequently dualistic) economy is now applied more broadly to the coexistence of rich and poor sectors (either rich and poor countries in the global economy or rich and poor people in the national economy), where there is often a tendency for the 'rich to become richer, while the poor remain poor or become poorer'. For a discussion and literature survey of the concept in this broader sense see Singer (1970).

Durkheim, Emile (1858–1917)

Emile Durkheim was the founding father of academic sociology in France and the most influential early theoretician of archaic or primitive societies. A Jew from north-east France, Durkheim followed the educational and ideological path of the positivist generation of great Republican academics. He was educated at the *Ecole Normale Supérieure,* taking a teacher's degree in philosophy and a doctorate (1893). After a short period as a *lycée* teacher, he spent a year in German universities studying social theory. On his return, he was appointed the first ever lecturer in 'social science and pedagogy' in a French university, at Bordeaux (1887). In 1902 he transferred to the Sorbonne, where he held a chair for the rest of his life.

Durkheim's seminal teaching and publications, included *De la division du travail*

social (1893) (*The Division of Labor in Society* 1933), *Les Règles de la méthode sociologique* (1894) (*The Rules of Sociological Method* 1938), *Le Suicide* (1897) (*Suicide* 1952), and work on socialism, family organization, the scope and development of German social theories. He attracted a cluster of gifted young scholars—mostly philosophers but also historians, economists and jurists (including Mauss, Hubert, Simiand, Fauconnet, Richard and Bouglé)—with whom he founded the *Année Sociologique* (1898). This was an essentially critical journal intended to cover the whole range of emerging social disciplines (social geography, demography, collective psychology, social and economic history, history of religion, ethnology and sociology proper). It was to become instrumental in developing and promoting a synthetic theory of social facts which overrode earlier disciplinary divisions.

Durkheim's later work included studies and lecture courses on the sociology of education, morality and moral science, pragmatism, family sociology, history of the social sciences, vital statistics and several other topics, but after the birth of the *Année* he was primarily concerned with the study of archaic societies, and especially with primitive religion and social organization. The problem of social cohesion in so-called poly-segmentary societies which, according to Durkheim, were based on mechanical solidarity (as against the organic solidarity of modern societies, based on a division of labour) had been a major theme in his doctoral thesis (1893), but there it lacked any significant ethnological underpinning. Durkheim developed an intense interest in primitive society much later, after reading contemporary British 'religious anthropologists', above all, Robertson Smith and Frazer. This resulted in a reorientation of his work towards the study of 'collective representations' and, more specifically, of religion, from 1896 onwards.

There were two sets of reasons, theoretical and methodological, for this shift. First, religion was considered to serve an essential social function, creating a strong community of beliefs and providing a basis for social cohesion. The sacred and the profane became the two essential categories in Durkheim's sociology, which ordered the system of social facts. Second, primitive religion, either because it was believed to be more simple and consequently easier to study, or because it appeared to be functionally interconnected with most other 'social facts' (like economy, law, technology and so on, which had gained a measure of functional autonomy in the course of later development) seemed to provide the key to a theory of social order. The religious system of archaic societies thus became a privileged topic of research for Durkheim and some of the most gifted scholars of his cluster, notably Mauss, Hubert and Hertz. One out of four review articles published in the *Année* was dedicated to social anthropology, and primitive societies now supplied, for the first time in French intellectual history, a central topic in public philosophical debate, which soon engaged other leading academics (like Bergson and Levy-Bruhl) as well.

In his anthropological work, Durkheim never surmounted the basic ambiguity of his approach to 'primitives', who were regarded either as prototypes, or as exemplifying the simplest imaginable occurrences of observable social types, or both at the same time. Moreover, he was initially sceptical about the heuristic utility of ethnographic data, and believed that preference should be given to historical documents over ethnographic information. His attitude changed, however, especially with the publication of more

professional ethnographies, like Spencer and Gillen (on the Australian aborigines), Boas (on the Kwakiutl Indians) and the Cambridge scholars of the expedition to Torres Straits. He discussed all these new studies in pains-takingly detailed critical reviews. They also supplied the data for his own contributions in the contemporary international debate concerning archaic societies. These fall broadly under two thematic headings: social organization and belief systems (and various combinations of the two).

The essay on 'La Prohibition de l'inceste et ses origines' (1898) (*Incest: The Nature and Origin of the Taboo,* 1963) obeyed to the letter his own prescription, 'Explain the social fact by other social facts'. Social institutions could not be explained by invoking instinctive behaviour. They must be accounted for purely in terms of social causes. Incest and exogamy derived from the nature of the elementary, that is, uterine, clan. Respect for the clan's totem manifested itself by a religious aversion to the blood of fellow clanspeople and, by extension, to sexual contact with the clan's women. The prohibition of incest was accompanied by prescriptions concerning interclan marriage. Some modern writers on kinship (for example, Lévi-Strauss 1949) recognize their debt to Durkheim, though they have submitted his theory to substantial criticism. Similarly, in his essays on totemism (1902) and Australian kinship (1905a), Durkheim seemed clearly to anticipate much later structuralist approaches. He identified, beyond the social categories of kinship, truly logical categories which, he suggested, could be understood as 'mathematical problems' (Durkheim 1905a). He went further in the exploration of such logical categories in a famous study, written together with Mauss, 'De quelques formes primitives de classification: contribution a l'étude des représentations collectives' (1903) (*Primitive Classification* 1963). This essay related ideas about space among some Australian and North-American tribesmen to their social organizations. Durkheim and Mauss argued that men 'classified things because they were divided into clans'. The model of all classification (especially of spatial orientation) is the society, because it is the unique whole (or totality) to which everything is related, so that 'the classification of things reproduces the classification of men'. Primitive classifications generated the first concepts or categories, enabling men to unify their knowledge. They constituted the first 'philosophy of nature'. Durkheim and Mauss suggested that in these classifications could be discerned 'the origins of logical procedure which is the basis of scientific classifications'. Durkheim would systematize these intimations in his last great work which focused on the social functions of religion proper.

L*es Formes élémentaires de la vie religieuse* (1912) (*The Elementary Forms of Religious Life,* 1915) was the culmination of Durkheim's anthropological studies. His focus upon Australians (and to some extent on American Indians) was grounded on the methodologically essential (and still ambiguous) assumption that their clan system was the most 'elementary' observable. The elementary religion is that of totemic clans. It contains the germ of all essential elements of religious thought and life.

Durkheim starts from the proposition that religious experience cannot be purely illusory and must refer to some reality. The reality underlying religious practice is society itself. Religion is 'above all a system of ideas by which individuals represent the society they belong to'. Moreover, 'metaphorical and symbolic as it may be, this representation is not unfaithful'. Certain types of 'collective effervescence' produce religious beliefs, or help to reconfirm beliefs and values of religious relevance. The type of religion is also

determined by social structure. For example, the cult of the 'great god' corresponds to the synthesis of all totems and to the unification of the tribe.

Religion also helps to interpret or represent social realities by means of their projection in a special symbolic language. Thus, mythologies 'connect things in order to fix their internal relations, to classify and to systematize them'. They represent reality, as does science. The function of religion is ultimately social integration, which is effected by 'constantly producing and reproducing the soul of the collectivity and of individuals'. Symbolism is the very condition of social life, since it helps social communication to become communion, that is, the fusion of all particular sentiments into one common sentiment'.

Durkheim's religious anthropology has been severely criticized by field researchers, yet without ceasing to inspire scholars concerned with archaic religions. At the time, his sociology of religion had an immediate public appeal in consequence of the conflict then raging between the Church and the Republican State. The study of primitive religion allowed Durkheim to adopt a purely scientific posture, while offering an historical criticism and a sociological evaluation of contemporary religious institutions. (He once described the Catholic Church as a 'sociological monster' (1905b).)

Ethnographic evidence drawn from primitive societies also led to heuristic generalizations concerning the nature of social cohesion, its agents and conditions. Ethnology, moreover, lent itself more easily than other established disciplines (like history or geography) to Durkheimian theorizing, because it was an intellectually weak and institutionally marginal branch of study (see Karady 1981). Durkheim's theoretical anthropology, together with the work of his followers and debating partners (such as Levy-Bruhl, Mauss, Hubert and Hertz) contributed decisively to the birth of French academic field anthropology between the two world wars. A later generation of French anthropologists, including Griaule, Métraux, Dumont and Lévi-Strauss, continued to exploit Durkheim's heritage, while critically re-evaluating it. As a consequence of its Durkheimian roots, French social anthropology never broke with the other social sciences, and retained a penchant for high-level generalization.

E

eating disorders

The term eating disorder is used in psychiatry to denote two closely related syndromes, anorexia nervosa and bulimia nervosa (and their variants). The central feature of these disorders is a set of characteristic beliefs and values concerning the pre-eminence of body shape and weight in self-evaluation. These beliefs and values, which are extreme in form, drive much of the disturbed behaviour in people suffering from these disorders, such as the pursuit of thinness in anorexia nervosa and the extreme methods of compensating for overeating in bulimia nervosa.

Epidemiology

Anorexia nervosa is a disorder mainly affecting young women in economically developed countries. The typical age of onset is 14 to 16 years, although childhood onset is well recognized and may be increasing (Lask and Bryant-Waugh 1992). The community studies of prevalence suggest that around 1 per cent of the at-risk population (i.e. young women) have the disorder. Case register studies have revealed a marked rise in the number of cases of anorexia nervosa coming to specialist attention. Thus, in Rochester (Minnesota) over the 50-year period from 1935 to 1984 the rate among young women rose from 7.0 to 26.3 per 100,000 person years (Lucas *et al.* 1991). There is a definite possibility that these findings reflect a true increase in the incidence of the disorder.

Bulimia nervosa was first described as a distinct syndrome in 1979 (Russell 1979). The disorder is almost exclusively found in women with a wide age range affected. The consensus is that 1–2 per cent of young women fulfil strict diagnostic criteria for bulimia nervosa with a greater number suffering from variants of the disorder (Fairburn and Beglin 1991).

Clinical features

People with anorexia nervosa markedly restrict their food intake, typically by adhering to a low carbohydrate diet. There is an associated preoccupation with food and eating. About half alternate between periods of marked restriction and bulimic episodes. Vomiting and laxative abuse are common. People with anorexia nervosa often deny that they have any problems and frequently insist, despite their emaciated state, that they are fat.

The profound weight loss in anorexia nervosa has a number of adverse effects on physical health (Mitchell 1986), such as amenorrhoea, low body temperature, low blood pressure and rapid heart beat. Starvation carries a marked risk of numerous complications including osteoporosis, liver function abnormalities and impaired cardiac function, as well as adverse psychological effects, including concentration impairment, irritability and depression.

The striking clinical feature in bulimia nervosa is the grossly disturbed eating habits, particularly the bulimic episodes. These are episodes of gross overeating which are experienced as occurring outside of voluntary control. They can occur many times a day. Bulimic episodes are fairly uniform in character: the eating is invariably carried out in secret with the food usually eaten quickly with little attention paid to taste; and the food eaten is typically those items the person is at other times attempting to avoid. Body weight tends to remain within the normal range, reflecting a balance between the episodes of overeating and various compensatory behaviours designed to counteract the effects of bulimic episodes. The most common method is self-induced vomiting which frequently terminates bulimic episodes. Purgatives are also used, sometimes in considerable quantities, as is exercise and further efforts at dietary restriction. People with bulimia nervosa have concerns about their body weight and shape similar to those found in people with anorexia nervosa. They tend to overestimate their own body size and persistently feel fat. Symptoms of depression and anxiety are marked in these people, and suicidal ideas and acts not uncommon.

Aetiology and maintenance

The aetiology of eating disorders is poorly understood, but it is widely accepted that a combination of biological, psychological and social factors are implicated. The relevant aetiological factors can be divided into those which predispose, those which precipitate and those which maintain the disorder.

Predisposing factors

Being a young woman in an economically developed country is a clear risk factor for eating disorders, presumably because of the social pressures to be slim. Eating disorders run in families. This is consistent with both a genetic and an environmental explanatory account. There is little firm evidence that a particular family environment is pathogenic, but this may be because the critical prospective comparative work has not been conducted. Twin studies suggest a genetic contribution to aetiology. A family history of obesity and of affective disorder have also been found to be important. While childhood sexual abuse is raised in people with eating disorders compared to psychiatrically well controls, the rate is no higher than in those with other psychiatric disorders. Finally, a history of anorexia nervosa is a definite predisposing factor for the development of bulimia nervosa.

Precipitating factors

The onset of eating disorders is often (though not always) preceded by a significant life event, but there appears to be no specificity in the form of such events. Loss of control over eating of the form seen in bulimia nervosa is almost invariably preceded by a period of dietary restriction. Such dieting itself may be preceded by teasing or adverse comments about the person's appearance.

Maintaining factors

Two consequences of weight loss are important in the maintenance of anorexia nervosa. First, the sense of achievement and the associated boost in self-confidence is often a spur to further dieting. Second, when the weight loss is extreme certain starvation effects serve to perpetuate dietary restriction: depressive symptoms lower self-esteem which encourages further dieting; and slow gastric emptying, by heightening the sense of fullness following eating, is a disincentive to eat. In bulimia nervosa the disturbed behaviours and cognitions drive each other in a vicious circle: concerns about weight and shape provoke dieting; dieting leads to lapses and overeating; overeating provokes further concerns about weight and shape and leads to vomiting and further dietary restriction; and this in turn leads to further overeating. This cycle can maintain itself without interruption for many years.

Treatment

There has been little systematic research into the treatment of anorexia nervosa. The mainstay of treatment has been hospitalization and nursing care, involving the refeeding of patients together with nutritional education in the context of emotional support (Russell 1970). The short-term results of such an approach are good with most patients being restored to a healthy body weight within three or four months. Day-patient

treatment programmes have been described and encouraging results reported (Piran and Kaplan 1990). An impressive improvement to the general management of anorexia nervosa has been reported in controlled research by adding family therapy to post-hospital care (Russell *et al.* 1987).

There has been a considerable amount of controlled research into both the pharmacological and the psychological treatment of bulimia nervosa (Fairburn *et al.* 1992). It has become clear that, although a modest antibulimic effect is achieved with antidepressant medication, the clinical benefits are generally not maintained with patients relapsing whether or not they persist with the treatment. Far better results have been obtained using psychological treatments. There is some support for the use of a focal psychotherapy, but most of the research concerns the use of cognitive behaviour therapy (Fairburn and Cooper 1989). Excellent results have been found using this treatment with improvements well maintained (Fairburn *et al.* 1992). This cognitive behaviour therapy for bulimia nervosa has been produced in a self-help format (Cooper 1995) and good results have been reported.

Outcome

Studies of the outcome of patients with anorexia nervosa have revealed high rates of persisting disturbance (Ratnasuria *et al.* 1991). The mortality rate appears to be around 15 per cent with the most common cause of death being suicide (Hsu 1990). The outcome of less severe cases of the disorder is unknown but likely to be considerably more favourable.

Few studies of the outcome of bulimia nervosa have been reported. Although there have been no natural history studies it appears that without treatment the disorder runs a chronic course. Follow-up of patients who have received cognitive behaviour therapy has revealed a favourable prognosis for the great majority.

ecology

The concept of ecology finds its immediate historical origins in Darwin's 'web of life', although such a non-Aristotelian view of the relationship between entities had been increasingly common since the eighteenth century. The term itself *(ökologie)* we owe to Ernst Haeckel (1834–1919). By the opening years of the twentieth century, crude generalizations and theory had been translated into empirical studies, beginning with the natural history of plants.

Ecology might briefly be described as the study of relations between living species, associations of different species, and their physical and biotic surroundings through the exchange of calories, material and information. As such it has been centrally concerned with the concept of adaptation and with all properties having a direct and measurable effect on the demography, development, behaviour and spatio-temporal position of an organism. Within this framework, the main preoccupations of contemporary biological ecology have been with population dynamics, energy transfer, systems modelling,

nutrient cycles, environmental degradation and conservation; and, since the 1970s, especially with the application of neo-Darwinian thinking to socio-ecology

In the social sciences, the concept of ecology in the strict sense was introduced first into human geography, via biogeography, and many geographers soon came to redefine their subject in explicitly ecological terms. By the 1930s, the Chicago school of urban sociology under the tutelage of R.E.Park and E.W.Burgess was describing its conceptual baggage as human ecology. Such an epithet was claimed to be justified on the grounds that analogies were drawn directly from the biological lexicon to explain spatial relationships, such as 'succession' for the movement of different class groups through urban areas. For a short time Chicago ecology was extremely influential, but it finally floundered on its own naïve analogies, crude empiricism and functionalist inductivism.

A number of the most fruitful applications of ecological approaches in the human and social sciences have been associated with anthropology. This has been so despite the dual intellectual dominance of Emile Durkheim (1858–1917) and Franz Boas (1858–1942) during the first three decades of the twentieth century, which had thoroughly crushed a nineteenth-century concern with environmental determinism. But although environmental issues were considered for the most part peripheral, and the environment accorded a constraining rather than a determinant role, there have been a number of important studies dealing with environmental interactions in this tradition. Boas's (1888) own work on the central Eskimo might be mentioned, as well as that of Mauss and Beuchat (1979) on the same subject. The general theoretical position is set out clearly in Daryll Forde's (1934) *Habitat, Economy and Society.*

The first really explicit use of the concept of ecology in anthropology is found in the work of Julian Steward during the 1930s (Steward and Murphy 1977). In Steward's theory the concept of cultural adaptation becomes paramount, and the key adaptive strategies of a particular culture are located in an infrastructural core of social institutions and technical arrangements directly concerned with food-getting activities. The recognition of distinctive adaptive strategies provided the basis for the delineation of cultural types, which Steward maintained evolved multilineally, rather than in the unilinear fashion subscribed to by many nineteenth-century thinkers. Steward's work has been very influential (and has found admirers in other disciplines), but his theory of cultural ecology entailed an interpretation of the concept of adaptation, together with a fundamental division between organic and super-organic levels of explanation, and between a core of key adaptive traits and a neutral periphery, which more recent writers (Ellen 1982) have been inclined to reject.

Advances within biological ecology linked to the notion of ecosystem, the empirical measurement of energy flow and the employment of the language of cybernetics and systems theory, led during the 1960s to a new formulation of ecological problems in the social sciences: in archaeology, geography, and also in anthropology The prominence given by Steward to the superorganic level of organization was passed over in favour of a view of human behaviour in many respects functionally equivalent to that of other animals. The description of ecological interactions became more sophisticated, involving computations of carrying-capacity, estimates of energy intake, output and efficiency for different groups and activities. There also developed an interest in the way in which cultural institutions might serve to regulate certain systems of which human populations

are part. All of these trends are demonstrated in the seminal work of Rappaport (1968), undertaken on a Maring clan from Highland New Guinea.

Sustained interest in the theoretical problems of systems approaches, plus an increasing number of detailed empirical analyses of particular cases, has, however, bred scepticism concerning simplistic notions of adaptation and system, and the more extreme proposition that certain kinds of small-scale society have built-in mechanisms for maintaining environmental balance through homeostasis (Ellen, 1982; Moran, 1990). Recent work has emphasised much more how people actually cope with environmental hazards (Vayda and McCay, 1975), employing the methods of economic individualism and, in the case of optimal foraging theory, evolutionary ecology (Winterhalder and Smith, 1981). This trend has been countered in the work of Ingold (1986) who has explicitly attempted to disaggregate post-Stewardian general ecology, and who speaks instead of humans being simultaneously involved in a field of ecological relations and a field of consciousness which cannot be reduced to adaptionist or other Darwinian explanations. There has been a general rekindling of interest in the evolution of social and ecological systems (Ingold, 1980), focusing on positive (rather than negative) feedback, and moving towards more explicitly historical approaches. Work in this latter area has drawn in particular on historical demography and on the French Annales school (Viazzo, 1989).

The other major impact of ecological concepts in the social sciences has been in relation to political environmentalism, and to environment and development. Under the guidance of figures such as Garrett Hardin and Kenneth Boulding, economic thinking has been placed in a broader biospheric context, and the 'growth model' rejected both in relation to advanced industrial and developing societies. Practical concern for environmental degradation, the profligate use of finite resources, the calculated advantages of 'alternative' technologies and worries for biodiversity conservation have spawned theories of sustainable development (Oldfield and Alcorn 1991; Redclift 1989). Some writing in this vein is distinctively Utopian, some is concerned with practical matters of implementing specific controls; some seeks to modify the existing world-system though retaining capitalist relations of production, others a rapprochement between Marxism and environmentalism (see Redclift 1984). Increasing attention is also being paid to the cultural construction of nature (Croll and Parkin 1992), indigenous technical knowledge (e.g. Richards 1986), the management of collectively owned resources (McCay and Acheson 1987), and environmental history (Crosby 1986).

econometrics

As the main concern of economics has shifted away from description and institutional analysis, economists have sought to quantify the relationships underpinning their models more precisely. In part this concern has been prompted by the desire to forecast the future behaviour of economic variables—for example, the response of aggregate consumption expenditure to changes in disposable income, or the effect of income tax changes on labour supply and the willingness of individuals to participate in the labour market. For such quantitative forecasts to have any value, it is essential that the empirical relationships on which the predictions rest should be relatively stable, both in terms of their structural characteristics and their coefficient values. It is less important that the

empirical relationships should conform to the specification of a fully articulated economic model of the phenomenon under consideration, since, in practice, 'naïve' models may yield good forecasts and it may be quite impossible to observe the variables or to estimate the parameters in an elaborate model. There is, however, another reason for quantifying economic relationships which necessarily implies that careful model specification is essential if the resulting empirical estimates are to be of any value. This arises when the economist wishes to use the estimates to test hypotheses about the relative importance of different factors or economic variables which simultaneously determine some particular aspect of economic behaviour.

These distinct uses of quantitative economic relationships—i.e. forecasting and the investigation of economic hypotheses—have meant that econometrics, which is the branch of economics and statistics devoted to the empirical estimation of economic models, has developed in a number of quite separate directions. This tendency has been encouraged by the nature of the data available to econometricians. Much of classical statistical theory was developed for the purpose of making inferences from data collected in controlled experiments, typically involving some kind of randomized design in which all combinations of variables have an equal—or, at least, a known—probability of occurring. Economists must be satisfied either with time-series data produced by governments or other bodies, or with responses to sample surveys of a cross-section of the population during some period of time. Because their data is not experimentally generated, econometricians have been obliged to develop special techniques to deal with the characteristics of different types of data. For example, the user of aggregate time-series data must always check for the possibility that the errors about a particular equation are systematically correlated over time—this is called serial correlation. For the user of cross-section data, there is the consistent problem that the sample of observations may be non-random because, for example, self-selection means that certain types of individuals either refused to answer the questions or were excluded from the sample.

These and many other similar considerations mean that it is never simple to interpret data concerning economic relationships. Since the classical statistical assumptions rarely hold, econometricians are unable to separate questions concerning the validity of their statistical assumptions from issues relating to the specification of the model which they are estimating. As a result, the progress of empirical economic work has been characterized by interlocking disputes about econometric methodology and the relevance of the equations modelling aspects of economic behaviour. This means that it is often difficult to set up decisive econometric tests of particular hypotheses, especially as the underlying theoretical models may be specified in terms of variables which can, at best, only be approximately measured in practice. Nonetheless, econometric work has frequently prompted economists to reformulate or extend their models, either because the estimated equations had a poor forecasting record or because their explanatory power was rather low.

Historically, the development of econometric techniques has run parallel with changes in the availability of economic data and in the amount of computing power. Econometrics began to establish itself as a distinct discipline in the late 1920s and early 1930s—the Econometric Society was founded in 1931 with help from Alfred Cowles who was interested in forecasting stock market price movements—but it grew most rapidly in the

years after the Second World War. This was because the political commitment to full employment using Keynesian policies prompted governments to monitor macroeconomic developments much more closely The availability of time-series data on aggregate economic variables, and interest in forecasting aggregate demand encouraged econometric work on the relationships which comprise a simple Keynesian model of the economy. Two elements of such a model attracted particular attention: the consumption function in which consumption (or saving) is linked to disposable income, and the investment function which expresses aggregate investment in terms of the growth of aggregate demand (or production), interest rates, and other variables. While there are a number of competing formulations of the consumption function, econometric work on this has always appeared to be much more successful than that dealing with the investment function. It was found to be very difficult to forecast aggregate investment reliably, and estimated relationships differ significantly between time periods so that even though work has continued since the early 1950s there is no general agreement on the best specification for this relationship.

Interest in making forecast of individual components of effective demand gradually evolved into the estimation of large macroeconometric models designed to forecast the overall macroeconomic behaviour of particular economies, as well as to investigate the implications of changes in aggregate variables for specific sectors of the economy or categories of expenditure. Work of this kind was initiated by Klein in the early 1950s (e.g. Klein and Goldberger 1955), but by the late 1960s advances in data and computing power had allowed econometricians to compile and simulate large-scale macroeconometric models. Despite considerable scepticism about the reliability of the forecasts produced by these models, their use has become an indispensable part of the process of making macroeconomic policy in all developed countries, so that argument tends now to revolve around the merits of competing models rather than about the value of making such forecasts. As macroeconomic models have become larger and more specialized, it has also become increasingly difficult to understand the factors which determine the way in which they behave as a whole. Hence, during the 1970s, econometricians started to focus more on the properties of complete models rather than on the performance of individual equations within the model.

Another application of econometrics that has been developing since the 1950s combines the interest in forecasting with the scope provided by econometric models for testing propositions derived from theoretical models. This is the estimation of single, or systems of, demand equations using either aggregate data on prices and consumption patterns or information collected in surveys of household expenditure. Initially, the main purpose of this work was to estimate income and price elasticities of demand for specific goods. This remains an important consideration, but theoretical work on consumer behaviour has shown that, if consumer expenditure decisions are derived from some kind of maximizing model, it is necessary to impose quite stringent conditions on the specification and parameter values of systems of demand equations. These restrictions include homogeneity in income and prices, symmetry of cross-price effects, and negative substitution effects. The results of testing these restrictions illustrate the difficulties of using econometric work to test theoretical models. Most studies have found that some or all of these restrictions are rejected by the data, but the response of economists has not

been to discard the maximizing model of consumer behaviour but rather to investigate more elaborate specifications of the demand equations until the restrictions are not rejected. It is never possible to test the general restrictions implied by theoretical analysis except by adopting specific functional forms for the equations under investigation, so that statistical evidence against some hypothesis may be interpreted as implying either that the functional specification is inadequate, or that the basic theoretical model is wrong. In cases such as demand analysis, where the underlying theory is highly developed, econometricians have inevitably tended to regard their results as tests of specification rather than of general theoretical propositions. Only by the accumulation of negative evidence for a wide range of specifications is it possible to regard such work as undermining prior theoretical assumptions.

The availability of large-scale cross-section surveys—and of panel data sets in which individuals/households are interviewed at regular intervals over a period of years—has prompted the recent development of econometric techniques to deal with qualitative or limited dependent variables. These are variables which take on discrete values—e.g. 0 or 1 corresponding to 'no' or 'yes' responses to certain choices—or for which the range of permissible values is limited—e.g. it is not possible to work for a negative number of hours. The estimation of such microeconometric models is typically much more expensive than for classical regression models, and in most cases the amount of data to be handled is many times greater than for macroeconometric work. Hence, this work would have been impossible without the great improvements in computer hardware and software since the late 1960s. The principal applications of these techniques have been in the area of labour economics to the analysis of choices concerning labour supply and participation, education, job movement, retirement and migration. The results of this work have generated much interest among economists working on other topics, so that the range of applications may be expected to continue to increase rapidly as also will the techniques of analysis and estimation.

Econometrics has developed to the extent that it dominates applied work in most branches of economics. Indeed, even economic historians use econometric analysis—often under the title 'cliometrics'—in discussing issues such as the impact of railways on US or British economic growth, and of technical change in both agriculture and industry. The major improvements in the volume and quality of economic statistics and in the availability of large-scale sample surveys which stimulated many econometric developments during the period 1950–80 are not likely to be repeated. Thus, future developments in the subject will necessarily focus on methods of extracting more information from the data which are available. In practice, this will mean that applied economists and econometricians will have to devote more attention to the theoretical and statistical specification of their models in order to clarify the assumptions underpinning tests of particular hypotheses. Fortunately, the speed of technical change in computing is such that the cost of investigating more complex models, which has been prohibitive in the past, will not be a significant consideration in the future.

economic anthropology

Economic anthropologists study the ways that humans maintain and express themselves through the use of material goods and services. The field includes research on technology, production, trade and consumption as well as studies of the social and ideological arrangements humans develop for their material lives. In scope, economic anthropology embraces all contemporary and past societies, but early studies were carried out in 'non-western' communities. Economic anthropologists have now turned their attention to change and to the ways that different economic forms are mixed together, especially in contexts of differences in power and assertions of ideological superiority.

Economic anthropology has both ethnographic and theoretical aspects; one challenge for its practitioners is to join the two. The field also serves as a testing ground for major theories in economics. Contemporary macroeconomics has had little sway, but micro-approaches from neo-classical economics have had a marked influence, as made evident in many anthropological studies of decision making in markets, agriculture and domestic groups. Use of neo-classical theory, however, brings into play assumptions about the universal presence of human rationality, calculation and optimization; these assumptions do not always rest well with broader approaches in anthropology. For example, microeconomic theorists find that shared habits and culture are especially difficult to explain, except as illustrations of non-rational constraints on market-like behaviour.

Marxism has provided a different theoretical impetus in economic anthropology. In the 1960s and 1970s, Marxists raised important questions about the origin and use of surplus in society. Focusing on the control and use of labour, they identified several modes of production that were encountered outside the European context. In the 1980s and 1990s,

Marxist influence may be seen in studies of world-systems and their connection to local contexts; in interpretations of ideologies either as reflections or forms of resistance to dominant economies; and, in research, on the ways that productive modes are now combined in larger constellations.

Karl Polanyi and his associates, who developed an institutional approach, insisted that an economy based upon markets is not universal and that material life in many other societies is embedded within social relationships, such as reciprocity and redistribution. The Polanyi school, however, received less attention than Marxism and neo-classical thought, and the perspective has not been extensively developed.

The advocates of a fourth approach, cultural economics, urge that material life itself is a human construction. Some economic anthropologists of this type have looked at consumption and exchange as expressive modes that humans use and manipulate to advantage. Others have examined the models that a people construct of their productive system and their relation to the environment. Such local models often are built by projecting images of the human body or group upon the earth, crops or natural forces. Under the umbrella of this perspective as well, anthropologists have turned their attention to western economic theories and analysed them in light of their cultural assumptions and social contexts of production. By showing how western economics uses metaphors, folk notions of the self or ideas from other fields, these anthropologists would blur the line between modern and non-modern knowledge, challenge neo-classical claims to universality, and point to a different way of studying economic systems.

Advocates of these four approaches find few points of agreement, yet the several perspectives and ethnographic reports are cross-cut by a dualism that provides coherence to the field. In all material systems, humans face the practical choice between producing for the self and producing for the other. In the first case, material activities assume a reproductive pattern, and this supports group independence. In the second case, production is set within exchange: humans trade with others to secure needed and desired things. The first form may be termed community economy, the second is market economy. Real economies are complex, shifting combinations of the two, and humans often are pulled in both directions at once.

Community economies are formed around many types of association, such as households, compound groups, lineage segments, agglomerations of kinfolk, religious sodalities and settled villages. These locally based communities often are stacked one inside another, with each undertaking distinct material functions. Holding a commons is central to community economy. Consisting of land, material resources, knowledge, and even the ancestors, the commons is what a community shares and the source of its maintenance. Loss of the commons means dissolution of the community, while fracturing mutuality and trust within the community leads to loss of its commons. Rules of inheritance, access, use and disposal determine the differential allocation of the commons among community members. For example, game caught by a hunter may be distributed so that specific animal parts go to certain positions in the hunter's community, such as a chief, mother's brother and grandmother. Members of a community economy may expect or hope to achieve adequacy or sufficiency in their material lives.

The market economy is based upon competition among buyers and sellers who exchange between themselves. Unbounded in space, these exchanges ideally occur

between anonymous transactors. The goal of participation in the market is to secure a money profit which is private property. Profit may be saved, competitively displayed, or invested: accumulated profit or capital is the analogue of the community commons. For its participants, the market promises efficiency in the allocation of resources, but it never pledges adequacy in meeting the needs of all.

Many of the economies that anthropologists once studied conformed rather closely to the community model. But ethnographers always found pure exchanges within them by which persons traded with anonymous others in order to secure wanted items. By contrast, in market economies today many pure exchanges are leavened with communal features that temper the competitive element, as in the cases of oligopolies, corporations, unions and households. In like manner, most theories used in economic anthropology pertain to one or the other side of the economic dualism, but usually they must be blended to make sense of practical situations. Economic anthropology suggests that the inherent tension between the two forms of material life is ever-present; this dualism, with its shifting modes of expression, will likely remain a central focus of the field.

economic development

A central question in the study of economic development has turned out to be 'in what precisely does the economic development of a society consist?' For about twenty years after 1945, the accepted view was that the prolonged and steady increase of national income was an adequate indicator of economic development. This was held to be so because it was believed that such an increase could be sustained over long periods only if specific economic (and social) processes were at work.

These processes, which were supposed to be basic to development, can be briefly summarized as follows:

1 The share of investment in national expenditure rises, leading to a rise in capital stock per person employed.
2 The structure of national production changes, becoming more diversified as industry, utilities and services take a larger relative share, compared with agriculture

and other forms of primary production.

3 The foreign trade sector expands relative to the whole economy, particularly as manufactured exports take a larger share in an increased export total.

4 The government budget rises relative to national income, as the government undertakes expanded commitments to construct economic and social infrastructure.

Accompanying these structural changes in the economy, major changes of social structure also occur:

5 The population expands rapidly as death rates fall in advance of birth rates. Thereafter, a demographic transition occurs in which improved living conditions in turn bring the birth rate down, to check the rate of overall population increase.

6 The population living in urban areas changes from a small minority to a large majority.

7 Literacy, skills and other forms of educational attainment are spread rapidly through the population.

This conceptualization of economic development as the interrelation of capital accumulation, industrialization, government growth, urbanization and education can still be found in many contemporary writers. It seems to make most sense when one has very long runs of historical statistics to look back over. Then the uniformities which this view implies are most likely to be visible. One doubt has always been whether generalizing retrospectively from statistics is not an ahistorical, rather than a truly historical, approach. It presupposes some theory of history which links the past to the future. The theory may not be transparent, or it may be unsubtly mechanistic and deterministic.

Another major doubt about the adequacy of the view of development described in processes 1–7 centres around the question of income distribution. If the basic development processes described above either do not make the distribution of income more equal, or actually worsen the degree of inequality for more than a short period, some theorists would argue that economic development has not taken place. They prefer to distinguish economic growth from economic development which, by their definition, cannot leave the majority of the population as impoverished as they originally were. For them, indicators of growth and structural change must be complemented by indicators of improvement in the quality of everyday life for most people.

The latter can be of various kinds. They can focus on the availability of basic needs goods—food, shelter, clean water, clothing and household utensils. Or they can focus on life expectation tables and statistics of morbidity. The availability and cost of education opportunities are also relevant. Although the distribution of income may be a good starting-point, the distribution of entitlements (to use a concept expounded by A.K.Sen 1981) to consume of all kinds is the terminus. Similar kinds of consideration arise when one examines the role of political liberty in economic development. Is rapid growth and structural change induced by an oppressive, authoritarian regime true development? Those who object to the 'costs' of the development strategies of the former Soviet Union or the People's Republic of China do not think so. From a libertarian standpoint, they refuse to accept the standard account of economic development as sufficiently comprehensive.

The difficulty here is clearly with weighting all of the different indices involved to arrive at a single measure of the degree of development in this extended sense. Perhaps it cannot be done; and perhaps, if policy rather than international league tables is our main concern, this failure is not very important. The most familiar recent attempt in this vein is the United Nations Development Programme's *Human Development Report* series (UNDP 1990–).

Linked with these questions about the meaning of development is the problem of conceptualizing the process of development. Perhaps the most famous of all models of this process is the classically-based model of Sir Arthur Lewis (1954). This attempts to capture the simultaneous determination of income growth and income distribution. Its key assumptions are the availability within traditional, technologically backward agriculture of surplus population (surplus in the sense that their marginal product in agriculture is zero); and the existence of a conventional subsistence wage in the industrial sector which does not rise as the surplus agricultural population is transferred to industrial employment. The transfer of labour from agriculture to industry at a constant wage rate (which may or may not involve physical migration, but usually does) permits industrial capitalists to receive an increasing share of a rising national income as profit and to reinvest their profits in activities which progressively expand the share of industry in the national output. Thus Lewis explained what he regarded as the central puzzle of economic development, namely to understand the process which converted economies which habitually saved and invested 4–5 per cent of the national income into economies which save and invest 12–15 per cent.

The Lewis model can be elaborated to explain other stylized facts of development. If labour transfer involves physical migration, urbanization will follow. If capitalists are defined as those with an accumulation mentality (as Lewis does), they can operate in the public as well as the private sector, and expansion of the government share in national output can be understood in these terms. If industrial employment in some sense requires labour to be healthy and educated, these major social changes—including a demographic transition—may be set in train.

Much of the subsequent literature on economic development can be read as an extended commentary on the Lewis model. Neo-classical economists have criticized the assumptions of the model, questioning whether labour in the agricultural sector does have a zero marginal product, and whether labour transfer can be effected without raising the real wage rate (Lal 1983). Alternatives to the Lewis model as an account of rural-urban migration have been proposed (e.g. by Harris and Todaro 1970).

The Lewis model's sharp focus on physical capital formation has been strongly questioned. Some critics have gone so far as to deny that physical capital formation is necessary at all to economic development (e.g. Bauer 1981). A less extreme view is that human capital formation or investment in the acquisition of good health and skills is a prerequisite, rather than an inevitable consequence, of the successful operation of physical capital. A balance is therefore required between physical and human investments to ensure that an economy raises its level of technological capability in advance of a physical investment drive.

The sectoral destination of investment in the Lewis model also provoked a strong reaction. Although less narrowly focused than Dobb's model (1955) where investment

priority was given to the capital goods sector of industry, the Lewis model's focus on investment in the modern industrial sector was seen as inimical to the development of agriculture, and the failure of agricultural development was increasingly identified as a cause of slow growth and income maldistribution in developing countries (as argued by Lipton 1977). The debate about sectoral investment balance has since been subsumed into the analysis of project appraisal, as pioneered by Little and Mirrlees (1974) and others. This provides, in principle, a calculus of social profitability of projects in all sectors of the economy. It is worth noting, however, that the rationale for the social pricing of labour in the Little and Mirrlees method is based on the Lewis conception of agriculture-industry labour transfer.

The Lewis model recognized the possibilities of state capitalism as well as private capitalism. The infrequency in practice with which such potential has been realized has led to demands that governments confine themselves to their so-called 'traditional functions' and the creation of an incentive and regulatory framework for the promotion of private enterprise. This has been one of the major thrusts of the counter-revolution in development thinking and policy of the 1980s (Toye 1993).

Foreign trade plays a minor role in the Lewis model and other early models of economic development. This reflected the pessimism of many pioneers (such as Prebisch (1959) and Singer (1950) about the tendency of the terms of trade of primary commodity producers to decline. It also responded to a belief that, historically, isolation from the world economy had spurred development in Meiji Japan (Baran 1973) and Latin America in the 1930s (Frank 1969). More recently, the expansion of manufactured exports has been seen as a major element in the astonishingly successful development performances of East Asian countries like South Korea and Taiwan. Debate still rages, however, about whether this kind of trade expansion experience validates liberal trade and finance policies, or an intelligent and selective style of government intervention in these markets (as argued by Wade 1990).

The concessional transfer of finance and technical assistance from developed to developing countries fitted well with the Lewis emphasis on physical capital formation as the key to growth and income distribution. More recently, the effectiveness of aid has been questioned. Although simple supporters and enemies remain vocal, it is common now to see more clearly the complexities of the aid process, and to stress the many lessons that have been learned from hard experience to improve the likelihood of aid achieving its desired objectives (e.g. Cassen and Associates 1986; Lipton and Toye 1990).

Somewhat greater agreement exists on the facts of recent economic development than on the methods of bringing it about. That many poor countries have experienced much economic growth and structural change since 1945 is widely accepted. Few still claim that growth in developed countries systematically causes increased poverty in other, poorer countries. A weaker version of this thesis is that there is an ever-widening gap between richest and poorest, which can arise when the welfare of the poorest is constant or rising. Even this weaker version is controversial, on the grounds that countries are ranged evenly along a spectrum of wealth/poverty, and thus to split this spectrum into two groups of rich and poor in order to compare group statistics of economic performance can be somewhat arbitrary. In fact, the measured growth rates of developed

and developing countries since the early 1960s show relatively small differences and ones that may well lie within the margins of error that attach to such estimates. The countries classified as developing also show increasing differentiation among themselves. But, although the overall record of economic growth at least need not give cause for deep gloom, certain geographical regions do appear to have markedly unfavourable development prospects. Such regions include sub-Saharan Africa and parts of South Asia, and of Central and South America. The reasons for their poor prospects vary from place to place. Some are held back by severe pressure of population on cultivable land; some by inability to generate indigenous sources of appropriate technical progress; some by the persistence of intense social and political conflict; some by unenlightened policy making; and some by the continuing failure to evolve a worldwide financial system which does not tend to amplify the inherent unevenness (over place and time) of economic development.

It is also true that the rapid increase in the world's population makes it possible for the *absolute* number of people whose consumption falls below a given poverty line to increase, even when the *percentage* of the world's people who are poor on this definition is falling. This is what seems to be happening at the moment. Despite all the evidence of widespread economic development, theoretical and practical work on poverty alleviation has, therefore, a growing urgency and relevance.

economic dynamics

The concept of economic dynamics denotes both the movement of an economic system (or parts of it) over time, and the body of theory that provides an analytical understanding of the former type of phenomenon. The analytical representation of dynamics, that is, the identification of features giving identity to any given economic system over time, is the critical link between economic history and the theory of economic dynamics. Thus it provides a connection between the two views of economic dynamics (Baranzini and Scazzieri 1990). The consideration of change as a regular feature of modern economic systems is at least as old as the early recognition of persistent forces or repeated once-for-all impulses as a normal factor shaping the structural evolution of an economic system over time (the contributions by Adam Smith, Thomas Robert Malthus *(Essay on the Principle of Population)* and David Ricardo are instances of the former approach; Malthus's *Principles of Political Economy* are an instance of the latter approach). The recurrence of phases of contraction and expansion also received early recognition. The literature on economic crises provides an early example of the importance of the time-horizon in the analysis of economic dynamics (distinction among short, medium and long waves).

The concept of general economic crisis (Aftalion 1913; Robertson 1914; 1915; Tugan-Baranovsky 1894) is rooted in the idea that both contraction and expansion affect in due course the whole economic system, even if they would normally originate in particular subsystems (such as construction sector, machine tools sector or railways). Subsequent analysis often considered dynamic patterns relative to the whole economic system, thus overlooking a fine distinction of structural elements and dynamic factors. In this way, the attention paid to structural evolution (the change in the composition of aggregate magnitudes, or aggregate forces, as the economic system moves across time) receded into

the background, and economic dynamics came to be considered as the analysis of long-run factors of change (such as capital accumulation, technical progress and population dynamics) and of their interaction. This type of investigation was often carried out on the assumption that long-run dynamic factors are constant and that the saving-investment equality is maintained throughout (steady growth under equilibrium assumption) (see Domar 1946; Harrod 1939; Kaldor 1957; Pasinetti 1962; Robinson 1956; Solow 1956; see also Baranzini 1991; Kregel 1973).

Recent work in the field of economic dynamics has pursued a number of distinct, yet interconnected, research lines. First, the interest in long-run dynamic factors has led to the consideration of learning and increasing returns as the most important endogenous phenomenon influencing economic evolution (Aghion and Howitt 1992; Romer 1986; 1990). Second, the mathematical theory of dynamic systems has been applied to the consideration of economic issues ranging from the stability of economic equilibrium (Gandolfo 1981) to cyclical patterns (Goodwin and Punzo 1987; Lucas 1987) and the emergence of new structures associated with qualitatively new features taken up by the dynamic relationships between economic variables (Anderson *et al.* 1988; Arthur *et al.* 1991a; 1991b). Third, the decomposition of economic aggregates and forces has stimulated renewed interest in the analysis of structural economic dynamics, which may be associated with the stage-structure of economic transitions (Hicks 1973; Lowe 1976; Quadrio-Curzio 1986), the long-run transformation of broad economic aggregates (Pasinetti 1981; 1993), the emergence of new and relatively persistent patterns of economic organization and their diffusion across economic sectors and over time (Landesmann and Scazzieri 1994).

economic efficiency

In a restricted sense, economic efficiency is often taken to mean that resources or inputs should be used so as to produce an output in the cheapest possible way. It is the cost of a combination of inputs which is of interest, not the use of a single input. The economically efficient input combination is the one which yields a specified output level at the least possible cost. The use of a single input (e.g. energy) can, of course, be further reduced, but so much extra is then needed of other inputs that the total cost increases. Alternatively, one can speak of efficiency when a firm produces as much as possible (maximizes output) at a specified total cost. This illustrates the fact that the concept of efficiency is used in different production contexts. Similarly, one can speak of efficiency in consumption. Individuals who aim at achieving the highest possible level of utility, subject to their income, will allocate their income between goods in such a way that the marginal rate of substitution between any two goods (the satisfaction derived from an extra unit of the first commodity divided by the satisfaction derived from an extra unit of the second commodity) is equal to the ratio between their prices. This is the criterion for efficiency in consumption.

The concept of economic efficiency, as attributed to the Italian economist Vilfredo Pareto (1848–1923), is usually interpreted in a broader sense. Pareto specified a condition of optimal or efficient allocation of resources which is referred to as the *Pareto condition.* According to this criterion, a policy change is socially desirable if everyone is made better off by the change (the weak Pareto criterion), or at least some are made better off, while no one is made worse off (the strong Pareto criterion). When the possibilities for making such policy changes have been exhausted, society is left with an allocation of commodities that cannot be altered without someone being made worse off. Such an allocation is called *Pareto-optimal* or *efficient.*

Under certain conditions, a market economy will be Pareto efficient. The important relationship between competitive equilibria and Pareto optimality is that, when a competitive equilibrium exists, it attains Pareto optimality. This result, which is known as the *First Theorem of Welfare Economics,* provides a strong argument for the advocates of a pure market economy. The result says that the perfect market economy simultaneously yields efficiency in production and consumption.

economic geography

Economic geography is a sub-discipline within human geography concerned with describing and explaining the production, distribution, exchange and consumption of goods and services within an explicitly spatial economy. Economic geography was first institutionalized in the late nineteenth century, and arose in large part because of its potential contribution to European colonialism. Early economic geographers attempted to provide, first, a global inventory of tradeable resources and their conditions of production (Chisholm 1889), and, second, an intellectual justification for the marked differences in levels of economic development between colonized and colonizing countries based upon environmental determinism (Huntington 1915).

From the 1920s onwards, however, economic geographers increasingly looked inwards, and practised a regional approach that involved delineating the unique character of the economy of a given place. Employing a standardized typology, one based upon such categories as production, transportation, markets, and so on, facts were carefully compiled and organized for a particular region and then compared to those of another. By so doing, the uniqueness of place was proven.

Following the post-war enthusiasm for things scientific, economic geography's young Turks mounted a quantitative and theoretical revolution in the mid-1950s, transforming the discipline into spatial science. Initially this movement was defined by the use of a set of sophisticated parametric inferential statistical techniques, but increasingly it involved the importation of rigorous abstract theories and models drawn from at least four different sources. First, from neo-classical economics came general models of competition and rational behaviour. Second, from physics came gravity, potential and entropy models that, in turn, were used to explain patterns of spatial interaction. Third, from the recouping of a hitherto forgotten nineteenth-century German location school came a series of locational models: von Thunen's theory of agricultural location, Weber's theory of industrial location, and later, Loesch's and Christaller's central place theory. Finally, from geometry came a slew of axioms, lemmas and theorems that could be used to underpin a set of explanatory spatial morphological laws (Bunge 1962). More generally, economic geographers who prosecuted spatial science believed that an autonomous set of spatial forces regulated the geography of the economy, and that they were identifiable only by applying the scientific method.

From the mid-1970s onwards spatial science was increasingly criticized. Spatial science's main mistake was in assuming that the spatial was independent of the social. Rather, as the Marxist geographer David Harvey (1982) argued, the spatial must be conceived as thoroughly socialized by the dominant mode of production, capitalism. Under Harvey's approach, if economic geographers were to understand capitalism's changing economic landscape they needed to grasp the basic tensions within the non-spatial core of the capitalist system itself. For Harvey this was possible only by returning to Marx; in particular, by making use of Marx's idea of the 'annihilation of space by time' Harvey (1982) provided a brilliant reconstruction of capitalism's geography of accumulation.

The political economy approach that Harvey introduced into economic geography in the mid-1970s still remains the dominant paradigm. Subsequently, it has been elaborated and constructively criticized in at least five different ways, thereby defining the current agenda of the discipline.

First, in the mid-1980s Doreen Massey (1984) embellished Harvey's argument by suggesting that just as the spatial is socialized, so the social is spatialized. 'Geography matters', as she crisply put it. To show that it mattered, Massey (1984) argued that the character of a place is a result of the specific combination of past layers of investment made there. That character, however, reacts back and recursively influences the nature of yet future rounds of investment. As such, place is not passive, but an active component in the determination of the spatial division of labour. More generally, Massey's conception of the relationship between place and economy became the basis of the British 'localities project' that subsequently generated an enormous amount of research and debate within economic geography (Cooke 1989).

Second, there has been an attempt to flesh out the institutional structure that comprised Harvey's social relations. Of particular importance has been the French Regulationist school, and their twin concepts of a regime of accumulation and a mode of regulation, along with the historical instantiation of the two as Fordism and post-Fordism. These last two terms have become central to the work of economic geographers interested in contemporary industrial restructuring. The works of Allen Scott and Michael Storper (Storper and Scott 1992) are especially important, combining as they do theories of the French regulationists with detailed research on flexible production systems and industrial districts. Their post-Weberian theory, as they term it, has been especially useful in understanding the rise of both new high-tech industrial spaces, such as Silicon valley, and the renaissance of older craft centres, such as the Veneto region in Italy.

Third, following hints by Harvey, there emerged a burgeoning literature on financial services, and, more broadly, on the quaternary service sector of which they are part. Such work is often centred around corporate decision making within a broader context of globalization. The argument is that higher echelon business services (producer services), including financial ones, are concentrated in a few very large world cities, for example, London. Those centres, in turn, are linked by complex flows of information made possible by recent innovations in telecommunications. Furthermore, while such world cities are the loci of power and control within the global economy, they are also world consumption centres, spawning an urban underclass that provides many of the services necessary for that consumption to be maintained.

Fourth, stemming from Harvey's concern with the geography of accumulation, there continues work on economic development both at the regional and the international scales. At the international level, much of the emphasis has been on analysing the strategies and effects of transnational corporations, and the emergence of both a new international division of labour, and new growth complexes, particularly those in Southeast and East Asia (Dicken 1992).

Finally, as a reaction to Harvey's implicit conception of the social as equivalent only to class, there have been a number of attempts to widen the discussion so as to include gender and race. Feminist economic geographers have sought both to criticize what they see as the phallocentric basis of the discipline, as well as to offer a series of case studies that demonstrate that gender matters (MacDowell 1991). Works that explicate racialization within economic geography are less numerous, but a cluster of studies exist on ethnic entrepreneurs and enclaves.

In sum, economic geography has been the great borrower, taking ideas conceived in one discipline, and refashioning them so that they are useful in understanding the economics of a *geographical* world. Such a task seems especially pertinent as that world is becoming, if not everyone's oyster, at least the oyster of capital.

economic growth

Economic growth is usually taken to mean the growth of the value of real income or output. The word 'real' signifies that only changes in quantities, and not changes in prices, are allowed to affect the measure. It is not equivalent to growth in welfare or happiness, although it may have important consequences for both, and there has been much debate about its benefits and costs (Beckerman 1974; Olson and Landsberg 1975). Measurable real income means, in turn, the maximum rate of measurable real consumption of goods and services that could be sustained indefinitely from the chosen point of time forward. It therefore presupposes that the costs of maintaining that rate of consumption are fully met, for example, that flocks are renewed, that roads are maintained, as also are the numbers of people and levels of their health and education. In principle, properly measured income would be net of the costs of environmental degradation, and would allow for depletion of minerals, thus acknowledging concerns which, however, have often been exaggerated (Meadows *et al.* 1972; World Bank 1992). If income were all consumed, we would have a static economy in which all outputs would be maintained, but in which economic arrangements would be essentially unchanged.

To make the economy grow requires economic arrangements to change, and the cost of making these changes is *investment.* This can take many different forms, for example, increasing flocks, building more or better roads, making more or better machinery, educating more people, or to a higher standard, undertaking research and development, and so on. Countries will grow faster the more of their incomes they devote to investment and the more efficient that investment is. The former Soviet Union invested a large fraction of its income, but it was so inefficiently done that little benefit accrued to its people. Experience suggests that efficiency is best secured through a free market system, although there are some important large-scale investments that need to be centrally planned. In a market system, profits are important for investment for several reasons. They generally provide most of the savings and finance. High profits strengthen business confidence to undertake investment. Apart from taxation, the higher the share of profits, the lower must be the share of wages, and the stronger the incentive to employ more labour. But profits must not be the result of monopolistic agreements to raise prices and restrict output. Such agreements reduce growth, as does government protection from foreign competion.

The above emphasis on investment as the source of economic growth may seem little more than common sense. For a long time, however, economists have placed their emphasis on technical progress. This is because of the seemingly well-established empirical finding that, taken together, investment and employment growth can account for little more than one-half of the growth of many developed economies. The residual, unexplained, part of growth is then attributed to technical progress, which, according to theory, is the discovery of new ways to increase output from given inputs of labour and

capital (Denison 1967; Solow 1957; and many others). Unfortunately, the residual in these studies results from the mistaken way in which the contribution of investment to growth has been estimated. In reality, this contribution has been far greater, and there is no residual to be explained (see Scott 1989; chs 1 and 3).

The earlier growth theories of Solow and others not only attributed too little growth to investment but also claimed that in the long run increasing the share of investment in output would leave the rate of growth unchanged. What mattered was technical progress, but its causes were left unexplained. Subsequently, attempts were made to explain it, usually by attributing it to some narrow category of investment such as research and development expenditure (Grossman and Helpman 1991; Romer 1990). These theories have erred in implicitly treating most investment as if it were just reduplication of existing assets. Since investment is the cost of *changing* economic arrangements, it is never mere reduplication. It is this which explains why investment opportunities are continually present, and are not steadily eliminated as they are taken up. Undertaking investment creates new opportunities as fast as it eliminates others. In the nineteenth century, for example, it was the railways and the telegraph which opened up the interior of the USA and which led to the development of much larger manufacturing and distributing enterprises able to take advantage of economies of scale and scope (Chandler 1990). Research and development are important, especially for some industries (e.g. aerospace, electronics and pharmaceuticals), but they are by no means the only important generators of investment opportunities. The fastest growing countries in the world are not those with the greatest expenditures on research and development. They are those Asian countries in which wages are low and profitability and investment are both high, as businesspeople take advantage of their ability to imitate and catch up the more developed countries in a relatively free market system. They have also benefited through a large transfer of workers from agriculture to manufacturing and other enterprises. Perhaps the chief constraint on growth in the west is the fact that a prolonged boom, which is needed to generate high rates of profit and investment, results too soon in unacceptably high rates of inflation, and leads western governments to slam on the brakes. By contrast, the Asian countries seem able to sustain their booms for much longer.

economic history

Economic history, as a combination of two disciplines, has had a rather varied evolution. Whereas in Britain and most other European countries economic history has been regarded as a separate discipline, such an academic distinction has not existed in the USA where, indicating the dual nature of the subject, economic historians can be found in either the history department or the economics department. Since the 1960s there has been a marked change in the study of economic history, first in the USA, then elsewhere, with the expansion of quantification and social-science model building, changes that have affected other subdisciplines of history. Economic history in the USA has now become dominated by scholars trained as economists.

The definition of a field of study can be a rather uncertain thing, although there are generally two somewhat overlapping approaches to delimiting a discipline. One definition relates to the set of questions being studied. Economic history can be defined as the study of the economic aspects of the past, or as the study of the solution to the problems of the allocation and the distribution of goods and services that arise from the problem of scarcity. The second definition is based on the methods, techniques and concepts applied by scholars in studying problems. Applications of the basic tools of economics to historical problems would thus be considered to fall within the discipline. Given these two, at times inconsistent, definitions, it is sometimes difficult to be precise on the boundaries of economic history. This has become particularly so since the 1960s, where the basic concepts of economic analysis have been applied to wider sets of issues, and to problems which were until recently generally held to be outside the province of economics and of economic history.

Although the works of some earlier economists, including Smith, Steuart, and Malthus, contained historical data, the modern evolution of economic history in Britain from the latter part of the nineteenth century dates from the Irish historical economists, Cliffe, Leslie and Ingram, and the first of the Oxbridge economic historians, Rogers, Toynbee, and Cunningham. Toynbee's student, Ashley, who was also influenced by the German, Schmoller, came to hold the first chair in economic history in the English-speaking world, at Harvard in 1892, before returning to Britain. The first chair in economic history in Britain went to Unwin at Manchester, followed by a London School of Economics

(LSE) chair to Cunningham's student, Knowles, in 1921, with chairs over the decade between 1928 and 1938 to Clapham (Cambridge), Clark (Oxford), Power (LSE), Tawney (LSE) and Postan (Cambridge). The acceptance of economic history as a field of study was marked by the founding of the Economic History Society in 1926; publication of the *Economic History Review* began in 1927.

The development of economic history in the USA lagged behind that in Britain, with more attention in the earlier part of the twentieth century given to the histories prepared for the Carnegie Institution, dealing with agriculture, manufacturing, transportation and commerce, among other issues. These scholarly writings and document collections are still central in the work of many contemporary economic historians. There was no 'historical school' in the British sense, but the American 'institutional school' filled its role as critic of economy theory and was to play a key role in influencing the study of economic history and its offshoot, business history. The latter emerged with the appointment of Gras to a chair at the Harvard Business School in 1927. Also important in influencing the development of economic history in the USA was the founding of the National Bureau of Economic Research in 1920. Among the founders was the Harvard economic and business historian, Gay, but most influential was its long-time director of research, Mitcheil, and his student, Kuznets, with their emphasis on data collection and the studies of business cycles and economic growth. The Economic History Association was founded in 1940; its journal, the *Journal of Economic History* began publication in 1941. The work of most American (and British) economic historians prior to the Second World War, however, still reflected primarily the historian's orientation.

Economic history, being at the intersection of two disciplines, has often been involved in debates about methods and techniques. Before the 1960s, however, these debates were most frequently between economic historians and economists, and were concerned with the relative usefulness of abstract theory as contrasted with detailed institutional knowledge in understanding the past world and in prescribing policies for the contemporary situation. The German and English historical schools of the late nineteenth century arose primarily in reaction to what was felt to be the extreme abstractions of Austrian and Ricardian economic theory, with their extensive claims in regard to the universal applicability of economic theory as a guide to understanding past (and present) developments. Further, at this time the prescriptions of economic historians often pointed to the desirability of a wider range of state interference in the economy than was advocated by theoretical economists, a position buttressed by their claims of knowledge obtained from detailed examination of 'real' historical developments. Following Toynbee in Britain, there was often a social reform purpose central to historical studies. The classic *Methodenstreit* between Menger and Schmoller, which also raised questions about the usefulness and importance of induction and deduction as basic scientific approaches, is indicative of these debates with economists. Related points on the applicability of theoretical constructs arose in other debates between economic historians and economists, such as those at Cambridge between Marshall and Cunningham, and the 1920s series of articles, by Clapham and Pigou, on 'Empty Economic Boxes' (e.g. Clapham 1922; Pigou 1922)

There were some critiques stressing the advantages of the use of economic theory in the study of history. Heckscher's 1928 address to the International Historical Congress

was not unique, nor was it the first, although it remains among the clearest examples of A plea for theory in economic history' (Heckscher 1929). Clapham's *Encyclopedia of the Social Sciences* essay (Clapham *et al.* 1931) sounded the call of the quantitatively oriented, with its reminder of the importance of 'the statistical sense, the habit of asking in relation to any institution, policy, group or movement the questions: how large? how long? how often? how representative?' Yet it seems safe to say that prior to the Second World War most economic historians fought their interdisciplinary battles mainly against economic theorists, and, in their own work, more often followed the style and methods of historians rather than those of economists. As historians, the economic historians did broaden the range of questions and approaches to reflect some of the concerns of economists, but the work remained closer to the historical mainstream than it was to be in subsequent years.

In the USA, beginning in the late 1950s and 1960s, there occurred a significant shift in the training and interests of economic historians. The work of the post-1950s generation of economic historians, including Davis, Fogel, Gallman, North and Parker, as well as others trained as economists, generally falls under the rubric of the new economic history, but is also known as econometric history and cliometrics. It contains three different, and not always compatible, aspects, features seen somewhat in earlier works of economic historians, but not to such a pronounced degree. The first feature, one which reflected the interests of many social scientists in the post-Second World War period, was a heightened concern with problems relating to the long-term economic growth of nations (in the sense of an increase in the measured output of goods and services per capita). These studies rested more heavily on economic analysis and quantitative measures than did earlier work. The questions to be studied by economic historians were often guided by a search for messages to those nations currently underdeveloped, and the economic histories of the developed nations were regarded as case studies to be looked at for the secrets of their success. This focus on growth was to be found among economic historians in Britain and elsewhere in Europe, with important works by Rostow (1960) and by Deane and Cole (1962) on British growth in the eighteenth and nineteenth centuries helping to shape subsequent studies.

A second important influence was a growing reliance upon quantitative constructs, such as measures of aggregate national income, as a means both of describing the past and of posing questions for study. Economic history has always been quantitatively oriented because much of the basic data, such as prices and wages, are numerical. There had been a major multinational collection of price data under the auspices of the International Scientific Committee on Price History in the 1930s. In explaining the increased attention to statistical measurement, the crucial role of the National Bureau of Economic Research can be seen. It was the direct contribution of Kuznets (1941), in making national income an operational construct, that led to much of the work in preparing estimates of national income and of output and input by industrial sector for the late nineteenth and twentieth centuries which was undertaken beginning in the 1930s. It was only in, and after, the 1950s that detailed estimates, based on census data, of United States national income from 1839 onwards, and of British national income in the nineteenth century, were generated, and even later before similar estimates were presented for other countries and, in some cases, for earlier times. Quantitative work,

both by cliometricians and what might be called more traditional economic historians, greatly expanded after the 1960s with the development of the computer. The increased analysis of quantitative data by economic historians mirrors the expansion of econometrics as a tool used by economists, as well as the greater occurrence of quantification within other fields of historical study.

The third feature of recent work in economic history is the systematic use of economic analysis, particularly the application of conventional neo-classical supply and demand analysis. It should be noted that the claims to scientific history of the economic historians who used these methods differs from the claims of earlier scholars. To the earlier writers, scientific history meant the uncovering of the laws of motion of the social system, providing a key to understanding the past as well as predicting the future. Recently it has meant applying the tools of economics to answer specific questions that fit into the broader historical picture. As the critique of neo-classical economics has emerged among economists, however, so has criticism of its use in the study of historical problems. Similarly, the concern among economists with issues related to income distribution and power relations in society, whether influenced by neo-classical or Marxist models, has been reflected in the work of economic historians who have utilized census manuscripts, tax lists, and probate records to provide a fuller historical record of the course of inequality over the past centuries. The general attempt to expand the tools of economic analysis to what have been regarded as exogenous elements in the study of economic history has many applications: in the study of institutional changes, the examination of causes of technological change, the analysis of the causes and consequences of demographic movements (including both fertility and mortality changes), and the determination of the varieties of labour control to be found in different economies and over time.

In the post-Second World War period leadership in the new approach to economic history has been in the USA, with other nations generally following after a period of years. Yet the more traditional approaches to economic history, updated somewhat in method and approach, have continued to flourish in Britain and elsewhere, and economic history has retained its status as a separate discipline in Britain and other countries. In the USA, economic historians have again made the critique that mathematical economic theory has become too abstract and divorced from real-world issues, and that economics would benefit from reintroducing a more historical and empirical bent to the discipline, a practice that has, however, developed successfully in various fields of applied economics. Thus economic history has continued to contribute to both economics and to history.

economic man

In his classic work, *History of Economic Analysis,* Joseph Schumpeter (1954:887) refers to the concept of economic man as one 'particularly effective in promoting the critics' mirth or wrath'. This response reflects the fact that the concept is extremely vague and general, and in some versions undoubtedly does suggest an extremely crude perception of how to understand human behaviour.

The concept in a broad sense can be traced back far into the history of social thought, but first becomes important with the growth of economic analysis founded upon the assumption of rational individualism in the nineteenth century. In the strong version eventually developed by economists, economic man is characterized by a complete set of ordered preferences, perfect information about the world, and infinite computing power to calculate with. With this formidable equipment, he is able to maximize his individual welfare subject to constraints. Economic man embodies then the strongest possible notion of instrumental rationality, where the ends of action are immaterial but those ends are

rationally pursued.

From within economics the problems of this approach have been much debated. The uncertainty attached to outcomes has been emphasized, and the need to attach some probability to them stressed. The problem of the costs of acquiring information has also led to a wide-ranging literature, especially regarding how far we can make a rational assessment of the costs and benefits of acquiring information, when by definition we cannot know the content of that information. One popular general way of dealing with such problems is to stress the *limits* of human reason, and to work with a concept of 'bounded rationality' (Simon 1957), which stresses how humans attempt to make rational choices from among a small range of options, so overcoming the insuperable computational obstacles to assessing all possibilities. For Simon, humans 'satisfice' rather than maximize.

A quite different approach is to treat the assumptions of economic man as a purely deductive device, which can be used to develop certain predictions about the world, and which can then be checked against the evidence. In this approach, the character of the unrealistic assumptions about economic man are irrelevant, its usefulness as a concept is solely measured by the accuracy of the predictions derived from it (Friedman 1953).

Non-economists have not generally found this 'as if' defence of economic man persuasive. They have tended to regard its assumptions as relevant to judgements of its usefulness, but those assumptions as implausible. Those assumptions, for example, disregard any Freudian notions about different layers of human motivation. Human beings are always fully conscious of their motives, and lack conflicts in determining their behaviour. They also seem to bypass any discussion of how the *means* of calculation employed by economic agents are constructed. For example, what does it mean to maximize profit, when profit is an ambiguous word, with widely varying meanings in different contexts?

Whatever the philosophical and methodological problems, economic man remains a concept implicit in much modern economics. Partly this reflects a widespread belief that, by and large, humans roughly conform to the concept. In addition, the maximizing subject to constraint approach, which economic man underpins, is open to extensive mathematical manipulation, which any more complex picture of human motivation would tend to undermine.

economics

In the draft of the introduction to his monumental study of the history of economic analysis, Joseph Schumpeter (1954) writes as follows:

> This book will describe the development and the fortunes of scientific analysis in the field of economics, from Graeco-Roman times to the present, in the appropriate setting of social and political history and with some attention to the developments in other social sciences and also in philosophy.

Few contemporary economists view their subject as stretching back continuously to Graeco-Roman civilizations, and some would regard a close association with history or philosophy as unnecessary, if not positively undesirable. Yet Schumpeter's account takes up nearly 200 pages before reaching Adam Smith's (1776) *The Wealth of Nations,* which is where economics began according to a vulgar view.

There is no great contradiction here. A reading of Schumpeter shows that he, as much as any other commentator, recognizes that the study of economic questions underwent radical changes of method, and an accelerated pace of development, in the late eighteenth century. Yet contemporary historians of economic thought agree with Schumpeter in not attributing the beginning of modern economics to the European Enlightenment, still less to the Scottish Enlightenment and Adam Smith. On examination the mercantilist and liberal writers turn out to share as much in common as they have differences. As in other cases, a sharper contrast exists between modern and early thinkers together, and their pre-modern predecessors (on merchantilism, see Magnusson 1994).

What began, whenever it began, and accelerated in the late eighteenth century, was not the description, not even the analysis, of economic institutions and questions, all of which are ancient. It was a redefinition of the centre of focus for such studies. A part

justification of the simple belief that it all began with *The Wealth of Nations* is that the way in which Smith defined the subject is, in broad outline at least, recognizably the same as the subject defines itself today.

First, the renaissance idea that humankind is part of nature is sovereign. This frees economic analysis to apply rationalist and reductionist methods in order to attack economic superstitions, such as the belief that true wealth consists in the possession of gold.

Second, economics is liberated from morality, but not in the direction of an amoral political economy of nation-state power, which the mercantilists and others had explored. Rather many simple 'moral' views are discredited, often by the device of showing that their intentions fail to translate into moral outcomes. A phrase frequently used by Adam Smith captures this change of philosophy perfectly. Mercantilist restrictions are *unreasonable.* This means, of course, that like all institutions they are subject to critical rational review, and that they fail that test.

Third, if economics is not about selecting policies to promote the power of the sovereign, then what is it about? A view characteristic of the liberal individualism of the seventeenth and eighteenth centuries, again inherited by the modern discipline, has it that it is about the individual (or the individual family) and about the proper field, conceived as a wide one, for the pursuit of self-interest. The understanding that self-interest may be a socially constructive force is what separates the economist from the one who derives his views on economic issues solely from common sense. Equally, the understanding that self-interest may need to be channelled or even constrained to achieve good social outcomes is essential to a sophisticated economic insight.

Finally, this last tension, between the field for liberal policy, even *laissez-faire,* and the field for intervention, makes economics essentially concerned with policy. True there exist economic questions which are inherently abstract; questions addressed to the formalized issues which considerations of preference, decision and equilibrium throw up. Yet policy is never far away. As an illustration of the point, consider that no one would ever have wasted time on determining what is the level of normal prices if normal price was not considered as, at least potentially, an input to economic policy.

Description and analysis sound like science, but what of policy? Can there be a science of policy? Is indeed economics itself a science? The question is often asked thoughtlessly, without the enquirer having a clear notion of what counts as a science. Yet it conceals serious issues. Obviously economics is not physics, however physics may be conceived. Biology, or even climatology seem to be closer cousins. Economics has models, data and, certainly, simplifying assumptions. But it also concerns itself with values, with what is good or bad in economic states. Science is usually conceived of as value free; not in the sense that subject matter is chosen at random, but with the meaning that it concerns itself with what is, not with what ought to be.

Economics has tried to wriggle around this dilemma for most of its modern history. If there can be no ought to be, how can there be policy? And without policy, will not economics reduce to a kind of descriptive anthropology of economic life? If, however, values enter into economic discourse—a higher gross national product is good, fluctuations are bad, etc.—how is economics to escape from a mire of relativism in which its values are shown to be just one of many possibilities?

The question was posed most sharply by Professor Lionel Robbins (1952), who asked by what right economists maintained that the abolition of the Corn Laws in nineteenth-century Britain was a good thing. While it was good for manufacturers, and possibly for their workers, it was surely bad for landlords. Who were economists to say that landlords losses counted for less than the gains of manufacturers?

Showing that history was on the side of the manufacturers would hardly settle the matter. History after all was on the side of Cortés and against the South American aborigines at one time, but few people today regard that as settling the value issues. A different tack was tried by Kaldor (1939), and a similar argument explored by Hicks (1969). An economic change could be regarded as an improvement, argued Kaldor, if it carried the potential of making everyone in the economy better off. This fascinating argument, and its problems, almost define what the modern field of welfare economics is about.

The assumption that individual tastes are sovereign was not contentious for economists, although others might question it. Preferred by all had to mean better. Making individual self-interest basic to welfare evaluation goes back to Pareto and beyond. Hicks (1969) is a striking challenge to this view. Later investigation showed that even if the sovereignty of individual preference is conceded, there remain serious conceptual problems for welfare evaluation. The most fundamental statement of these difficulties is the hugely influential work of Arrow (1963), which shows that a social welfare function derived from individual preferences, according to weakly constrained principles, implies the dictatorship of one individual over the ranking of at least three possibilities. Arrow's axioms for the social welfare function have proved controversial (see Sen 1979) but there is no trick solution to a problem which just reformulates itself when the question is redefined.

Some economists have elected to throw away value neutrality and to investigate the implications for policy of specific value weights. Others have relied upon the important and useful fact that several important results in economic theory are value neutral in the sense that they hold true for all value weights. An example would be the very general result of public finance theory which says that lump sum taxation imposes less cost on those taxed (has a lower excess burden), for a given revenue collected, and regardless of how the burden of taxation is distributed, than any other form of taxation (see Atkinson and Stiglitz 1980: ch. 11).

This is not to say that one can easily manoeuvre around the problem that economic pronouncements are heavily value-laden. Lump-sum taxation completely severs the link between efficiency and distribution, and creates a Utopian world in which economic institutions function perfectly to take the economy to its utility possibility frontier, while leaving the policy maker to select a point on that frontier. In general, efficiency and distribution are more closely bound together when policy is designed with feasible taxes and other instruments to hand. Modern economics has made much of *incentive compatibility,* which means the design of institutions, including taxation, but much more as well, so that the individual agents involved will find it in their self-interest to do what the policy maker intends. On incentive compatibility and the associated concept of mechanism design, see Fudenberg and Tirole (1991: ch. 7).

Policy design as conceived by modern economic theory is hugely more complicated

and sophisticated than its eighteenth-century ancestor, with its sometimes simple 'get rid of irksome interference' approach. The role of the state and how it should best operate are well modelled in the context of the design of systems of taxation and regulation. Outside those particular areas, policy design needs a good deal of improvement, a point to which I shall return.

A good measure of how economics has grown and changed over its recent centuries of history is provided by the story of GNP (gross national product) or its equivalents. Before the twentieth century it would be no exaggeration to say that there was no well-developed flow concept of economic well-being. The wealth of nations, or regions or peoples, were the object of comment and investigation. Naturally, wealth and income, as the writings of Cantillon (1697–1734), Petty (1623–87) and Quesnay (1694–1774) confirm, are closely related concepts (see Cantillon 1755; Petty 1927; Quesnay 1759). Yet they part company in the short run, as when a depression lowers incomes substantially while little affecting wealth. To record fluctuations in national income at all precisely demands a systematic collection of statistics, via a census of production, which had to wait until the mid-twentieth century to become reality.

Before that happened, the theory of national income as a concept and as a measure of economic welfare had been developed. Pigou (1955) is a good short exposition. The theoretical framework was implemented in modern GNP accounting which has graduated in half a century from an academic exercise to perhaps the most important objective and indicator of government policy.

It is no surprise that the success of GNP accounting in measuring the level of activity for the economy has been followed by deep criticism of GNP as an objective of policy. More than one type of issue is involved and limitations of space prohibit a full discussion here. Yet two basic points are frequently encountered. They can be briefly labelled consumerism and the environment. In short, the consumerism argument says that GNP is biased towards a market notion of human welfare which overweighs capitalist lifestyle and consumption and underweighs non-market activities and lifestyle. Thus transport to commute to work, and health costs associated with commuting, enter into GNP, while the value of home-grown vegetables does not. Similar arguments become even more heated where the environment and finite resources are concerned. Modern industrial production based on the burning of fossil fuels boosts GNP. Yet the cost which is the reduction of the levels of those fuels remaining in the ground is not deducted from GNP. There are no easy answers to any of these issues; yet their existence reminds us of the change in focus of economic thought among professionals and non-professionals alike.

Probably the ideological side to economics explains why the subject has been prone to controversy and to discord between competing schools. In the Anglo-Saxon world, however, the predominant method has become the neo-classical approach. Most economists would agree with that view even when some would regret the fact. But what exactly is neo-classical economics, and what are the alternatives which have failed while the neo-classical variety has flourished?

In summary, neo-classical economics is built on the assumption that efficient markets arrive at an equilibrium in which the separate actions of rational maximizing agents are made consistent via market equilibrium (or market clearing) conditions. In the absence of externalities, it is then a *theorem* that the resulting allocation of resources is efficient in

the sense of Pareto. This is the so-called first fundamental theorem of welfare economics. The second fundamental theorem states that any Pareto efficient allocation can be made a market equilibrium when suitable lump-sum transfers place each agent on the right budget constraint. These two results fully clarify the relationship between efficiency and market equilibrium for competitive economies.

Such a clear intellectual framework makes it easy to classify the main lines of attack for anti-neo-classical economics. These concern

1 Motivation: are real-life economic agents maximizers who concentrate mainly on economic on self-interest?
2 Information: are these agents well-informed about prices—current and future—and about technology, and even about their own tastes?
3 Calculation: even given the information, and the objective, how can agents calculate the right action? And how can the market, or the market-maker, calculate the equilibrium?
4 Do markets function as the neo-classical model has it, or are they subject to price rigidities, imperfect competition or monopoly, market failure or missing markets?

Some of these arguments are old, some more or less modern. The economist's assumption about the motivation of 'economic man' have always seemed absurd, and immoral as well, to many outsiders. Thorstein Veblen (1857–1929) articulated passionately the problems with the computational abilities implied by the assumption that economic agents maximize (Veblen 1904). Keynes, on one interpretation, is partly about the macroeconomic effects of sticky prices. The idea that imperfect information is crucial to market failure may have been mentioned in the nineteenth century, but until recent years there is no analysis of the idea worthy of the name. Imperfect competition, especially duopoly, was analysed by Antoine-Augustin Cournot (1801–77) amazingly ahead of his time in the mid-nineteenth century, and analysis continued ever since. The idea that markets may be *missing,* as opposed to just not functioning well, is certainly modern, and is tied up with the again modern concept that sources of information and transaction costs should be modelled explicitly.

Now we come to a powerful paradox. As models developed from the shortcomings of neo-classical theory listed above become increasingly refined and sophisticated, they frequently and typically emerge from the work of economists of the neo-classical stable. Indeed the neo-classical critique of neo-classical economics has become an industry in its own right. In this situation a truly anti-neo-classical economics has not been easy to construct. Akerlof (1984) is one of the most interesting attempts to do so, and the frequently neo-classical nature of approaches based on highly non-neo-classical assumptions is suggestive.

It must of course be easy to construct an entirely non-neo-classical economics if one is willing to ditch enough baggage. In particular, theories in which agents behave according to more or less arbitrary rules produce radically different conclusions. But is the theory that results economics? This debate tends to separate theory and empirical investigation. *Ad-hoc* behavioural assumptions are hard to motivate or to formalize. Yet empirical studies have sometimes forced economists to recognize them as fact. A notable case in point is choice under uncertainty There some evidence is solidly against the most

powerful and appealing theoretical model. Yet the evidence seems to indicate what may be going on, and formalization of that has been attempted (see Machina 1987).

If there is little truly anti-neo-classical economics but mainly neo-classical economics in need of more refinement and sophistication, where does that leave the Keynesian revolution? Keynes (1973) saw himself as correcting a (neo)classical economics, the root specifications of which he was to a great extent willing to accept. Specifically, he argued that his unemployment could be encountered in a competitive economy in some kind of equilibrium. How far he was correct is a controversial question.

A modern North American school of New Keynesian thinkers maintains that Keynesian economics can be made to work only by introducing the specific modelling of market imperfections, information asymmetries and missing markets (see Blanchard and Fischer 1989). Certainly the treatment of expectations differs notably between Keynes and his modern successors in macroeconomic theory. Keynes argued for the subjectivity and irrationality of expectations concerning the future. Some modern theorists, by contrast, have gone to the opposite extreme by studying *rational expectations*— expectations as efficient and perfect as it is possible to be in the circumstances (Begg 1982). Although taken to its logical limit, this approach soon becomes mathematically elaborate and even indeterminate, there lies at the bottom of the debate some fundamental questions concerning Keynes's economics which have asserted themselves from the start of the Keynesian revolution.

With the flexible output prices assumed by Keynes, the theory asserts that an increase in effective demand will generate an increased output from the supply side by raising output prices relative to wage costs, that is, by cutting the real wage. How will this do when workers become aware of the fall in their living standards even when employed? There are various answers, none 100 per cent satisfactory. Keynes's discussion suggests that price inflation co-ordinates real wage cuts for all workers which they cannot achieve acting on their own, but will willingly accept when generalized because imposed by price inflation. New classical macroeconomists argued that output could not be increased by a boost to effective demand, as workers willing to accept a cut in their real wage could have taken it anyway. Hence only inflation surprises would increase output from the supply side. With rational expectations the scope for policy using inflation surprises would be severely limited. These arguments contained a germ of truth, as with the conclusion that rapid and expected inflation is soon discounted and has few real effects. Experience has shown that Keynesian effects continue to exist but that their scope is shorter run than the earlier Keynesian theorists assumed. Unemployment, however, has proved to be a growing problem for industrial countries, leading some to conclude that structural factors and dual labour markets may now be more important than the demand side.

The intricacies of rational expectations analysis provides an example of the growing use, and eventual dominance, of mathematics in economic theorizing. Economics in the 1990s is an applied mathematical subject to an extent unimaginable a century ago. This is not because the mathematically literate have conspired to squeeze out their less advantaged colleagues. Rather, mathematics is a natural language for economic reasoning. Obviously mathematics, including the differential calculus, lends itself to maximization. Yet for all the arguments ever since Veblen, maximization is seldom vital;

it often serves to provide a definiteness which could in principle be provided by alternative means. More important, however, is the power of mathematics in dealing with systems in which many influences make themselves felt simultaneously—a typical situation for social science models. Solving simultaneous equations really requires mathematics, and anyone who thinks that they can do it intuitively is practising self-deception.

Another great merit of mathematical reasoning is that it facilitates connections between theoretical and empirical work. For all the hostility of Keynes himself to mathematical economics and econometrics, the Keynesian revolution served to bring theoretical and applied economics closer together than had ever previously been the case. The development of national income accounting is a leading instance of this point. Yet economics and econometrics, though always second cousins, have never married. Rather, they have developed sufficiently separately to retain distinctive methods and styles. Hence the Econometric Society at its regular conferences in different parts of the world divides its programmes into economics and econometrics. Some resent this but no one could claim it to be an absurd division.

Growing specialization within economics does not affect only econometrics and is a result of the huge growth of the discipline and the proliferation of journals. Economists now tend to be development economists, labour economists, game theorists or specialists in other fields. The generalist hardly exists. Also, as a general category, *economist* is now more like *architect* than *man of letters.* It defines a profession. And clearly the number of people who can be said to earn a living by the practice of economics has increased massively since the Second World War. The total cannot easily be known but 150,000 worldwide would certainly not be an absurd guess.

That raises an obvious question: how successful is economics in the late twentieth century? In a crude ecological sense, economics is undoubtedly successful. It is reproducing itself with an awesome efficiency. However, on the test of its power as a problem-solving method, the success of economics must be regarded as more questionable. Indeed since the mid-1970s the subject has spent much of the time writing itself out of policy relevance. This is particularly marked with macroeconomics, where policy ineffectiveness theorems are central to a dominant mode of thought. It is true that the subject has always recognized that policy may be unable to improve on the market. With Adam Smith, however, that view owed more to scepticism about the usefulness of policy interference than to a faith in the perfection of unregulated markets as such. Recently, however, a faith in the perfection of markets, sometimes, but not always, qualified by the recognition of imperfect information and similar problems has attracted many and enthusiastic adherents.

The sometimes unfortunate effects of ill-considered deregulation exercises in the west may be blamed on that intellectual fashion. Of hugely greater importance in this context, however, has been the general failure of economics to provide useful modelling and advice for the former Soviet economies of eastern Europe following the fall of communism. That reform, which has required the creation of markets more than their liberalization, found economists more or less empty-handed. The result has too often been a flood of inconsistent advice derived from partial models based on western economies. It is too soon to write the history of the reform of former Soviet economies

and economic thought but it must be hoped that some deep lessons will have been learned from an experience which underlines the fact that economics, for all its modern reach and power, remains a subject embedded in particular historical experiences and presumptions.

economies of scale

The term economies of scale refers to the situation in which, at a given and unchanging set of input prices, the unit cost of production is lower in a plant of larger scale of (annual) output than in a plant of smaller scale. This happens because the physical requirement for labour and capital inputs per unit of output each tends to be lower the larger is the scale of annual output which the plant is designed to produce. This situation is contrasted with 'pecuniary economies of scale' in which the plant of larger scale may obtain inputs at lower prices. An example of economies of scale may be given for ethylene production in 1964 (Jackson 1982; adapted from Pratten 1971).

Scale of ethylene plant, output in thousands of tons per year	100	200	300
Acquisition cost of equipment (£million)	8.4	13.5	16.6
Acquisition cost of equipment per unit of output, or unit capital requirement (£ per ton per year	84	67.5	55.3
Unit cost (£ per ton)			
Unit materials cost	41.2	41.2	41.2
Unit labour cost	3.5	2.7	2.1
Unit capital cost (depreciation only)	8.4	6.8	5.5
Unit total cost	53.1	50.7	48.8

The main reason for lower unit labour cost is that an increase in the scale of this (process) plant requires a less than equi-proportionate increase in the number of workers and so unit labour requirement decreases with the scale of output.

The reason for lower unit capital cost is that the proportionate increase in the acquisition cost of the equipment (for a plant of larger scale) tends, systematically, to be less than the proportionate increase in the capacity of the equipment to produce annual output. (It must be made clear that, in economies of scale, each piece of equipment of smaller capacity is replaced by a piece of equipment (of the same type) but with a larger capacity (the meaning of 'scaled up'.) Conversely, the larger annual output is *not* achieved by simply duplicating or replicating pieces of equipment each of the same capacity.)

The relationship between the acquisition cost of a piece of equipment and the capacity of the piece of equipment is expressed in what may be called the 'power rule' (or 'six-tenths factor'; due to Chilton 1950; Williams 1947a; 1947b). The power rule is a most important basis for economies of scale.

The power rule is as follows. Let K denote the acquisition cost of a piece of equipment and V the capacity (however measured) of a piece of equipment; the subscripts i and j denote, respectively, pieces of equipment of the same type but different capacity, i being the larger capacity and j the smaller capacity; let s denote a parameter of the power rule. Then one version of the power rule is

$$(K_i/K_j) = (V_i/V_j)^s$$

Generally, $0 < s < 1$, and empirical values of s centre around two-thirds with values frequently approximating six-tenths. The value of s fundamentally derives from the two-thirds relationship between the surface area of a regularly shaped container (which is a basic determinant of the cost of the container) and the cubic capacity of the regularly shaped container (which determines the capacity of the container to produce a flow of output per period of time). Take the example of two cubes: the ratio between the surface areas is equal to, and varies as, the ratio of cubic capacities raised to the power two-thirds. Much fixed capital equipment is of the basic form of containers and so is subject to the power rule, but cost may not be exactly proportional to surface area and output may not be exactly proportional to cubic capacity, and such non-proportionality means that the parameter s may be either greater or less than the value two-thirds (hence the frequently observed value six-tenths).

If j the comparison piece of equipment is held constant, then for any i we can write a rearranged version of the power rule as

$$K_i = A \; V_i^s$$

(where $A = K_j V_j^s$). Because plants are basically assemblages of pieces of equipment, the power rule can also apply to plants (with K then denoting the acquisition cost of a *plant* and V the capacity of the plant measured in terms of *annual output*). For instance, in the case of the ethylene plant the following power rule may be estimated (for the data as given):

$$K_i = 0.473 \times V_i^{0.627}$$

If $s < 1$, then the acquisition cost of the piece of capital equipment or of the plant increases less than proportionately to the increase in capacity, so giving rise to economies of scale in relation to fixed capital: that is, the larger the scale of the plant, the lower is the acquisition cost of capital installed per unit of output per year. This relationship between scale of plant and unit capital requirement is a systematic one: dividing the rearranged version of the power rule through by annual output V gives:

$$(K/V)_i = A \; V_i^{(s-1)}$$

so that, with $s < 1$, the exponent $(s-1)$ is negative, and (K/V), the unit capital requirement, systematically declines as V, the scale of annual output, increases. Taking the example of the ethylene plant, doubling the scale of output would lead, according to the estimated relationship, to a change in unit capital requirement by proportion $2^{(0.627-1)} = 2^{0.373} = 0.772$, or a reduction of 22.8 per cent.

Handbooks of engineering publish tables giving, for each of a wide variety of types of equipment, values of K_j and V_j (the comparison values) and of s, the parameter of the power rule. These tables are used by engineers for preliminary cost estimation when

proposals for 'scaling up' a plant are under consideration (Perry *et al.* 1984).

For the economist, the interest of such data lies in the value of *s* for each type of equipment; nearly always less than 1 and centring around approximately . For example, in a sample of 288 types of equipment the average value of *s* was 0.6559 (with a standard deviation of 0.2656) (calculated from Woods 1975: Appendix C). Consequently we may conclude that economies of scale is a widespread and inherent feature of the behaviour of the acquisition cost of equipment or of a plant as capacity is 'scaled up'.

Diseconomies of scale may be defined, at the plant level, as an increase in the unit cost of production associated with an increase in the scale of output per period. Diseconomies of scale is adduced as one possible explanation for limitations on the size of a plant and is hence associated with the concept of a 'minimum efficient scale' of production and with the related concept of a 'U-shaped long-run average cost curve'. Diseconomies of scale explain the putative upward (right) part of the curve, with the bottom of the curve being at the minimum efficient scale (economies of scale explain the downward (left) part of the curve). Some reasons for diseconomies of scale are: the need technically for capital-labour substitution and/or automation as the scale of plant, and hence materials handling, increases; increasing managerial difficulties of co-ordinating work processes as plants become larger; increased unit transport and/or distribution costs arising from the need to sell the increased quantity of output over a larger geographic area.

education

Although dominated by psychology, the field of educational research was once largely restricted to the general discipline of philosophy. Other disciplines, such as anthropology, economics, political science and sociology, have become increasingly prominent.

The status of education as an applied field makes it difficult to identify any specific method or conceptual domain which would single it out from other fields. For most scholars and researchers, however, the study of education has meant investigating activities related to learning, usually within the context of the schools. The problems studied and the method employed vary a great deal, depending largely on the training and background of the researchers. However, in contrast to the earlier, philosophical studies which focused on the *aims* of education, the prominence of the behavioural and social sciences has signalled a shift in concern to questions of *means.*

As an applied field of study, the problems investigated in the area of education tend to follow closely the concerns articulated by leaders in business, government and the media. For example, in the late 1950s and early 1960s when US political leaders were primarily concerned with the space race with the Soviet Union and the so-called missile gap, a series of reports by the well-known educator, James B.Conant (1959) focused on the

lagging academic quality of education in the USA. Educational research in that country then turned towards developing curriculum units, teaching strategies, school procedure and design that would produce more scientists and engineers. In this period, for example, the 'New Math' flourished, and influential educators, such as the psychologist Jerome Bruner, proposed the teaching of science, mathematics and other academic programmes in the lower grades (Bruner 1960).

In the mid-1960s, social pressure built up over the civil rights issue, and the concern of much of the educational research community again shifted towards issues related to equality of opportunity. The work of Jean Piaget provided the intellectual basis for British and US curriculum researchers, who argued for relaxing the structure of the curriculum by allowing more room for the individual expression of interests. Some opposed these moves because they were too permissive, but the intention was to create a fruitful interaction between the developmental patterns found among children and the structure and pacing of curriculum knowledge. However, the apparently reduced emphasis on a hierarchy of knowledge (with science, maths and other college preparatory subjects at the top and vocational subjects at the bottom), and the renewed recognition of the importance of the interest of the individual child as a major factor in the learning process, appeared to be consistent with the wider concern for equality of opportunity.

Equality has continued to be a major issue in educational research and debate in a number of different areas. For example, James Coleman's (1968) analysis of data from thousands of American schools explored the extent to which different variables affect school achievement across racial lines. His finding that the class and racial characteristics of the student body had an important influence on individual achievement was rapidly used as intellectual support for the bussing of children across racially distinct neighbourhoods in an effort to achieve greater racial balance. At the same time other studies explored the effectiveness of pre-school programmes in raising the achievement levels of blacks and other children from lower socioeconomic classes.

At the time that educational research was exploring the pedagogical factors involved in maintaining inequality, the traditional meaning of equality of opportunity was first challenged. Goleman (1973), in an important article on equality of educational opportunity, suggested that the extent to which this ideal has been realized should be measured not in terms of equality of input—the resources spent on different children—but rather in terms of equality of results—whether or not the pattern of achievement is similar among different racial groups and minorities. Had this conception of equal opportunity been widely accepted, it would have significantly changed the rules of the game. This proposal would thus have mandated the allocation of unequal resources in some cases in order to achieve equal results.

Coleman's proposed conception was never fully accepted (Coleman himself offered it only tentatively). However, educational policy makers and politicians in the USA did begin to assign federal resources to special groups, such as handicapped people, blacks, women and non-native speakers of English; legal efforts were increased to redress racial imbalance in schools; and affirmative action programmes tried to increase the opportunities for minority students and women in universities and professional schools.

Even prior to Coleman's attempt to redefine the concept of equal opportunity, there had been other challenges to compensatory policies. The most publicized was an article

by Arthur Jensen (1969) which claimed that most compensatory programmes had failed, and therefore children of different intellectual ability should be taught differently. Children with high IQ scores, Jensen argued, should be taught conceptually by problem-solving methods. Children with low IQ scores should be taught through associative or rote methods. Jensen's article was controversial because of three propositions: IQ tests measure intelligence; in a population intelligence is 80 per cent explained by genetic factors; and blacks as a population score on the average consistently lower than whites on both standard IQ tests and culture-fair tests. Jensen concluded that environmental enrichment programmes were severely limited in their ability to raise IQ scores, and that educators would better spend their time and resources identifying conceptual and associative learners and teaching them through the methods appropriate to their learning style. Jensen himself believed that when IQ tests were appropriately refined to identify the two types of learners, blacks and other minority students would be more fairly treated. He also believed that teaching style would become more consistent with learning style and that conceptual learners from these groups would be less likely to fall victim to the prejudicial judgement of a few teachers. However, he also strongly implied that because of genetic factors blacks would continue to achieve at a lower rate than whites.

An uproar followed the publication of Jensen's article. The twin studies on which he had built much of his case for the prominence of genetic over environmental factors were discredited. Questions were raised about the whole concept of measurement as applied to intelligence and about the appropriateness of such tests for culturally distinct, minority children. In addition, Jensen's argument traded on the ambiguity of the claim that 'IQ tests measure intelligence'. The claim could mean that a conceptual limit exists beyond which an individual cannot reach and an IQ test measures it, or it could mean that IQ, tests measure the speed at which different individuals learn. This ambiguity is especially significant when it is understood that Jensen's view of associative and conceptual learning is inaccurate in at least one important respect. He believes that children can learn essentially the same basic material either through associative or conceptual methods, depending upon the learning style of the child. But, in fact, the children would be learning the same skills in only the most superficial sense. They might be learning how to translate symbols on a page into oral sounds, or learning to repeat number facts, thus giving the *appearance* of learning the same thing. However, each group also would be learning something about learning. One group would be learning that learning is a rote affair, while the other would be learning that it is essentially a conceptual and problem-solving activity. Jensen's article provides no evidence to support the view that such learning styles were irreversible, even though his own proposal seemed to rest upon this assumption.

The debate over Jensen's article was significant for a number of reasons. One of these went to the very heart of the question of equality of opportunity. For if equality of opportunity means that everyone is to be given the same chance, presumably ability differences should be the sole determinant of outcomes. However, if the major measure of ability, that is, IQ, tests, is put into question, so too is the justification for different outcomes.

Some scholars, while dismissing the significance of IQ tests, continued to justify differential outcomes and to argue against 'extraordinary' measures to achieve

educational equality. These arguments were often based on the view that governmental intervention creates unrealistic expectations and increases frustration and, possibly, violence. Environmental factors were considered important, but the most significant aspect of environment, the habits, discipline and foresight developed through class culture were thought extremely difficult to change. Because these studies took 'class-culture' and the habits and attitudes associated with it as an independent variable, they failed to examine the relationship between a student's habits, attitudes and achievement, and the work structures that were available to children from certain social classes.

This enlarged focus came only with a renewed interest in Marxist scholarship and, especially, with the work of two economists, Bowles and Gintis (1976). Their study concluded that schooling provided very little mobility, even when research controlled for IQ scores, and that schools largely served to reproduce and legitimize the personality characteristics required by the hierarchical relations found in advanced capitalistic countries.

The findings of Bowles and Gintis were challenged on a number of methodological grounds. However, one of the more significant effects of their work for educational scholarship was to reintroduce a Marxist perspective into the study of education in the USA. This perspective continued a tradition that was already established in Britain, western Europe, Australia, and in a number of Third-World countries. In effect Marxists have shifted some of the focus of educational research from the individual to the larger social, historical, cultural and political context of schooling (Apple 1982; Giroux 1981).

There is no uniform Marxist perspective. For example, the Brazilian educator, Paulo Freire (1973), draws not only on Marxist literature for many of his insights, but also on French existentialism, phenomenology, and Christian theology. Some analysts have adopted a structural approach and have examined the limits placed on the educational system by a hierarchical mode of production. Others, utilizing an ethnographic methodology, have explored the way in which a critical working-class consciousness is both developed and blunted in schools. There have been insightful studies on the reproduction of classroom knowledge for different social classes, on the production of educational materials and texts, and on the dilemmas created by radical educational thought for teacher education (Apple 1982; Giroux 1981).

While Marxist-oriented research represents a significant redefinition of the problem of education, it has remained a largely critical movement which only occasionally penetrates mainstream thinking about education. When inequality was a major issue for the educational community and the wider public, Marxism was able to gain a reasonable hearing. However, as unemployment rates in the USA, Britain and western Europe hit post-depression records, educational policy makers steered the agenda away from the issue of equality and towards the educational needs of the high technology revolution. Educational research is following suit as more concern is expressed about developing computer literacy, and about increasing the pool from which future scientists and engineers can be drawn. There have been calls to tighten up the curriculum, raise standards for admission into and matriculation out of higher education, and to reduce the 'frills' in the public schools. These concerns seem to signal a return to the era dominated by Conant.

Various forms of feminist scholarship have had an important influence on educational

scholarship, focusing it on questions of gender-specific learning styles, knowledge and moral reasoning. Moreover, under the influence of post-modernism, there has been a developing concern with issues of identity, and in the relationship between identity and knowledge. There is also renewed interest in the non-cognitive aspects of schooling and education.

The applied nature of educational research, and its failure to develop an independent research programme, suggests that its future direction will depend on political and economic developments. The last attempt to provide an independent focus for the study of education was developed by the American philosopher, John Dewey (see Boydston 1979). Since Dewey, educational philosophy has taken a different turn, one that emphasizes the anaylsis of concepts and linguistic clarity. Yet the deeper questions about education involve the understanding of intergenerational continuity and change, and the normative concerns that guide the process of social and cultural reproduction. While little systematic effort has been undertaken to explore the process and patterns of social identity, it is possible to specify some of the factors that such a research programme would involve. They would include an analysis of the kind of knowledge that is prized by a given society, the institutional arrangements to protect and carry on such knowledge, the methods used to identify and train those who will bear that knowledge in the future, and the way in which knowledge is distributed among different groups in the society. Such a programme would maintain the interdisciplinary character of educational studies but would provide a focus that has been lacking. It would also provide a critical point from which to appraise present educational practice.

educational psychology

The enduring difficulties that face both the academic and the professional sectors of educational psychology are due to three factors. First, educational psychology mirrors all the propensities and peculiarities of psychology. Second, and perhaps as a consequence, no distinctive approach or unified understanding of the field has evolved. Third, despite the professed concern with educational problems in general, the primary focus has in fact been schooling, as if all educational concerns are localized in schools.

Psychology in general has placed an enormous emphasis on quantification. Within educational psychology this trend has given rise to a huge testing industry, making tests, selling tests, giving tests, scoring tests, interpreting scores, categorizing and labelling people on the basis of scores, coaching test taking, doing research on and with tests, and so on. These activities have become so widespread, particularly in schools, as to make them a hallmark of the whole field, and educational psychologists have become effectively technicians of tests, measurements and evaluation, especially in the cognitive domain dealing with intelligence, aptitude and achievement (USA) or attainment (UK). The technical bias is so pervasive as to blind many practitioners to the damage that may be done to the test subjects (Hanson 1993).

This preoccupation with the tools of research has, of course, affected the substance. Persons *qua* persons tend to be diminished even as they are counted, aggregated, classified, labelled and treated. Not surprisingly, many significant questions have been ignored—for instance, how to handle young children's napping and sleeping patterns and

their disruptions; what they dream, and how that affects their life awake; how one's temperament contributes to the formation of a world-view; how to help a person develop courage and a sense of honour; or what nurtures maturity, integrity and wisdom.

Substantively, educational psychology remains a hodgepodge. Indeed, a cursory survey of graduate programmes reveals large portions of courses devoted to research design and analysis, measurements and evaluation, and computer applications. Side by side with these are courses on learning, development (mostly focused on child-adolescent phases), personality formation and pathology. The last category is heavily dependent upon the psychiatric tradition of diagnosis and classification. Among the relevant areas of enquiry which are normally absent from such courses are group dynamics, the process of teaching, or the nature of curriculum. It is still rarer for such a course to pay attention to other disciplines. On the level of theory, what is typically found is a doctrinaire adherence to a single fashionable approach. In the 1950s the Skinnerian school was dominant, to be replaced, in turn, by the approaches of Piaget, Chomsky, Vygotsky, and others.

There is little sense of the history of the field, and perhaps in consequence it is hardly surprising that the same mistakes tend to be repeated both in theory and in practice. One error has been to view the school experience in a linear, causal fashion, within its narrowest and most immediate context, without interpreting it in interactional, systemic terms against the broader backdrop of human meaning. As important as schooling has become, particularly to the young, an educational psychology that centres its attention exclusively upon this process is unlikely to achieve that rounded understanding of the person in the world which is required if we are to provide appropriate support, assistance and guidance (Bronfenbrenner 1979; Ianni 1989).

efficiency

see **economic efficiency**

ego

The ego is part of Freud's tripartite conception of the psyche. The ego emerges during the course of early development as that part of the mind concerned with perceptual awareness and sense of self. The ego also serves an integrating function and mediates between the individual and the external world. Like the id (instinctual energy), it is directed at obtaining pleasure but, because it is capable of reflecting the conditions of the outside world, it is tempered as well by concern for the demands of reality. Thus, although ego and id both serve the same end (pleasure), by sometimes seeking to postpone immediate gratification, the ego may conflict with the id. The third aspect of the psyche, the superego, which is roughly equivalent to conscience, develops through identification with a parent and integrating or assimilating that parent's values.

It is important to note that Freud did not mean to imply that the id, ego and superego are identifiable processes in the human brain. Rather, they are conceptualizations or abstractions used to refer to the interacting forces which govern behaviour. While 'ego' is the usual translation of the term used by Freud, *das Ich,* this ordinary German personal pronoun means literally 'the I'. By using this term, Freud firmly anchors this aspect of the psyche in our conscious awareness of ourselves. As Bettelheim (1983) has noted, the translators' use of Latin terms rather than everyday words serve to give the concepts spurious, scientific or medical connotations. The effect can be to reify them so that they become a formalized system rather than living tools which can help us to gain insights into the experience of being a person.

In his later formulations, Freud believed that one consequence of intrapsychic conflict (i.e. between the three aspects of the psyche) is the experience of anxiety. Such conflict may be alleviated by means of various defensive devices. One way would be to *repress* the conflicting desire from consciousness. This defence might be supplemented by *projecting* the repressed desire on to others so that they are seen as, say, being sexually motivated (even though they may not in fact be so). Or it may be *displaced,* as when repressed aggression is directed at another target. Another more productive way of alleviating conflict is to *sublimate* the repressed desire: as when sexual feelings are converted into concern for others, or into creative effort. Repression, projection, displacement and sublimation are all examples of ego defence mechanisms. In his later writings Freud, and also his daughter Anna among others, described a number of these. Note that defence mechanisms are considered to operate in largely an unconscious way. So, while the ego is the focus of consciousness, it should not be regarded as synonymous with it. Ego psychology offers a set of concepts which helps us to understand the processes whereby individuals cope with conflict, both within themselves and between themselves and aspects of the outside world.

In his later writings, the focus of Freud's interests shifted to (among other topics) such processes of inner conflict and integration and they have been taken up and developed by later psychoanalysts (e.g. Hartmann 1964).

elections

In politics elections are a device whereby popular preferences are aggregated to choose an officeholder. Choice by elections is now almost inseparable from representative democracy. Some see the opportunity for choice at periodic elections as the key element of western democracy (Lipset 1960; Schumpeter 1942). In 1975, thirty-three states did not hold elections to choose political leaders. For other states the crucial question is: what sort of elections? A further thirty-three states allowed only one candidate for each office. These are 'consent' elections (Mackenzie 1958). States which allow competitive elections and the possibility of replacing the government are largely western.

Election systems provide guidelines on such matters as who votes and how, frequency of election, how votes are counted, who stands for office and so on. In the twentieth century, most states have granted the vote to all (with a few exceptions) adult resident citizens. Over time, the suffrage has been extended from estates to individuals, and in the twentieth century to large categories formerly excluded on grounds of race, sex and property qualifications. The change has also been to equality or 'one man one vote one value' (Rokkan 1970).

In most states, responsibility for registering eligible voters lies with the government. A significant exception is the USA, where states leave registration to individuals. This partly explains why the turn-out in presidential elections since 1960 has averaged 60 per cent, compared to over 80 per cent in many western states. But US voters have more

opportunities to cast votes, in federal, state, local and primary elections, and in long ballots. At the other extreme, political and cultural pressures may produce remarkable turn-outs and verdicts, for example 99.9 per cent turn-out in the former German Democratic Republic in 1964.

Elections have several functions (Rose and Mossawir 1967). These include designating, directly or indirectly, the government; providing feedback between voters and government; demonstrating public support for or repudiation of a regime: providing a means for the recruitment of political leaders; and making the government answerable to the electorate. Functions may differ in states which have elections without choice, where a party's hegemonic or monopolistic position makes the outcome a foregone conclusion (Hermet *et al.* 1978).

In some countries (Belgium, Italy, Denmark and The Netherlands, for example) it is not the election but the inter-party bargaining following the election which determines the composition of government. Where the party system provides a choice between alternative potential majorities, voters do have such a choice. The impact of elections on policies depends in part on a programmatic disciplined majority party being in government. Until recently, the British two-party system was admired for providing a model of 'responsible party government'. More direct popular verdicts on issues may be made through referendums.

The nature of the electoral choice in each state is shaped by three sets of factors. First, the *object* of election, which may be to choose a constituency representative, party list or president. Second, the *party system,* or pattern of voting alignments (Lipset and Rokkan 1967), which in turn is shaped by cleavages in society, the electoral system, and the manoeuvres of elites. Third, the *electoral system,* particularly those provisions which aggregate votes and translate them into seats, that is, rules for counting and weighing votes.

A distinction may be drawn between the absolute majoritarian system, as in France, in which the winner has to achieve at least half the votes; the plurality (first past the post) system in many English-speaking countries; the various forms of proportionalism, including the pure proportional representation (PR) in The Netherlands (where 0.67 per cent of the vote gives a group a seat in the legislature); and those that combine elements of different systems (for example, Germany has PR for half the seats, subject to a party gaining at least 5 per cent of the vote).

Proportionalism was introduced at the turn of the century in divided societies to provide guarantees to minorities which felt threatened by universal suffrage or majority rule. Proportionalism furthers the goals of representativeness but, in the absence of a clear party majority, makes the choice of government less certain.

The British plurality system has usually achieved certainty in choice of the government while sacrificing representativeness. In October 1974 Labour had 51 per cent of the seats in the House of Commons with 39 per cent of the votes. The two systems maximize different values; most western states have opted for proportionalism, subject to qualifications.

We lack a good typology of elections. One may distinguish between degrees of choice, which in turn depends on the number of effective parties and the prospects of turnover in government. The USA has two parties, The Netherlands and Denmark a dozen. Italy,

Sweden and Norway have had very long spells of dominant one-party rule, and there has been only one change in France since 1958. In the USA Key (1955) distinguished between elections which were *maintaining* (reflecting normal party loyalties), *deviating* (in which short-term factors produced a short-term surge or decline in support for the parties) and *realigning* (in which there is a long-term change in the balance of party strengths).

There are limits on the decisiveness of elections as authoritative arbiters of policy. Incumbents of the bureaucracy and judiciary, and leaders of powerful interests, who are not elected by the voters, constitute checks. At present 'votes count, resources decide' (Rokkan 1966). The debate about the relative influence of socioeconomic factors or party political factors (and therefore elections) has not been conclusive. The influence of the government depends on the power centralization in society. In pluralist and market societies the government is only one decision maker among others, and competitive elections and majority rule are only two elements in representative democracy. Competitive elections do not ensure the political responsiveness of an elite; they have to operate in favourable conditions. There are alternative methods of facilitating popular choice and eliciting and demonstrating popular consent (for example, acclamation, seniority, rotation, and elite bargaining), but election is still the birthmark of a government claiming to be democratic.

elites

The term elite is part of a tradition which makes modern social scientists uneasy. At the same time, its use facilitates historical and contemporary analysis by providing an idiom

of comparison that sets aside institutional details and culture-specific practices, and calls attention instead to intuitively understood equivalencies. Typically, an adjective precedes the word elite, clarifying its aim (oligarchic elite, modernizing elite) or its style (innovating elite, brokerage elite) or its institutional domain (legislative elite, bureaucratic elite) or its resources base (media elite, financial elite) or the decisional stage it dominates (planning elite, implementing elite) or its eligibility grounds (birth elite, credentialled elite).

Two quite different traditions of inquiry persist. In the older tradition, elites are treated as exemplars: fulfilling some historic mission, meeting a crucial need, possessing superior talents, or otherwise demonstrating qualities which set them apart. Whether they stabilize the old order or transform it into a new one, they are seen as pattern setters.

In the newer approach, elites are routinely understood to be incumbents: those who are collectively the influential figures in the governance of any sector of society, any institutional structure, any geographic locality or translocal community. Idiomatically, elites are thus roughly the same as leaders, decision makers or influential, and not too different from spokes-persons, dignitaries or central figures. This second usage is more matter-of-fact, less normative in tone.

Still, elites are seen by many as selfish people in power, bent upon protecting their vested interests, contemptuous of the restraints on constitutional order, callous about the needs of larger publics, ready to manipulate opinion, to rig elections, to use force if necessary to retain power. A conspiratorial variant worries those who fear revolutionary subversive elites: fanatical, selfless, disciplined, competent and devoted to their cause, equally contemptuous of political democracy, constitutional order or mass contentment, willing to exploit hatred and misery, to misrepresent beliefs and facts, and to face personal degradation and social obloquy. Whether to preserve old patterns of life or to exemplify new ones, elites are those who set the styles.

When most social scientists talk about elites, they have in mind 'those who run things'—that is, certain key actors playing structured, functionally understandable roles, not only in a nation's governance processes but also in other institutional settings—religious, military, academic industrial, communications, and so on (Czudnowski 1982; 1983; Eulan and Czudnowski 1979).

Early formulations lacked this pluralist assumption. Mosca (1939 [1896]) and Pareto (see Meisel 1958) both presumed that a ruling class effectively monopolized the command posts of a society. Michels (1959 [1911]) insisted that his 'iron law of oligarchy' was inevitable; in any organization, an inner circle of participants would take over, and run it for their own selfish purposes. By contrast, Lasswell's (1936) formulation in the 1930s was radically pluralistic. Elites are those who get the most of what there is to get in any institutionalized sector of society and not only in the governing institutions and ancillary processes of organized political life. At every functional stage of any decision process—indeed, in any relevant arena—some participants will be found who have sequestered disproportionate shares of those values, whether money, esteem, power or some other condition of life which people seek and struggle for. They are the elite at that stage and in that context. For Lasswell (1977), the question whether a situation is fully egalitarian—that is, extends elite status to every participant—is an empirical question, not a conceptual one. Nor is there necessarily any institutional stability. Macro-analysis

of history shows periods of ascendancy for those with different kinds of skills, such as in the use of violence, propaganda, organization, or bargaining strategy

The social formations—classes, communities and movements—from which elites derive are not fixed. Elites are usefully studied by asking which communities they represent or dominate, which classes they are exponents or products of, which interests they reflect or foreshadow, which personality types they are prone to recruit or to shunt aside, which circumstances of time and place (periods of crisis, tranquillity or transition) seem to provide missions and challenges for them.

Elites may change their character. Elite transformation has often been traced. Pareto saw vitality and decay as an endless cycle. Students of Third-World modernization often note the heightened tensions within a governing elite that accompany the shift in power from a revolutionary-agitational generation to a programmatic-executive generation. Specialized elites —engineers, soldiers or priests—have often served as second-tier elites, recruited in the service of a ruling class that continues to set a governing style but whose members lack the skills to cope with new and pressing problems. Some scholars hold that a true elite emerges when those who perform the historic mission—whether to bring change, adapt to change, or resist to the end—become convinced that only they can carry out the mission properly Self-consciously, they come to think of themselves as superior by nature—for example, able to think like scientists or soldiers, willing to take risks like capitalists or revolutionaries (Thoenes 1966).

For some centuries, the historical forces that have been shaping the institutions of modern, urban, industrial, interdependent, institutionally differentiated societies have had a net effect that enlarges, democratizes and equalizes the life chances for elitehood. Everywhere the political stratification system typically resembles a pyramid, reflecting the striking cross-national uniformity that only tiny fractions of a country's citizens have more than an infinitesimal chance of directly influencing national policy or even translocal policies. At the same time, fewer disadvantages linked to social status, educational attainment, geographic residence, cultural claims, age and sex attributes, or institutional credentials now appear to operate as conclusively or comprehensively as in the past.

Viewed as incumbents, those who hold key positions in the governing institutions of a community are, collectively, the elite. They are the custodians of the machinery for making policy. Once a sector of society becomes institutionally differentiated, its ability to adjust to conditions on its own terms is likely to be seriously constrained. Even within its semi-autonomous domains, a custodial elite finds it hard to sustain a liaison network or co-ordinate sector-wide efforts (Field and Higley 1980). Medical elites are typically locality-rooted. Military services feud with one another. Scientists are engrossed with specialized lines of inquiry. Commercial elites are fragmented. Industrial giants are rivals.

In the modern world, when elites are seen as housed within conventionally recognized establishments such as military, diplomatic, legislative or party organizational structures, mid-elites and cadres are linked hierarchically to top elites and specialized to implement the specific public and system goals of their domains. When elites are viewed as the top talent in a vocational field—lawyers, academics, entrepreneurs, and so on—the elite structure is much more disjointed. Mid-elites are the source of eligible talent, engaged in

tasks having no necessary articulation with what top elites do, but nonetheless tasks that train and test, groom and screen individuals who may in due course reach top elitehood in their field (Putnam 1976).

Top elites in a custodial structure do not necessarily work well together. The structural complexity of legislatures is such that they typically have rather segmented power structures. In characterizing a military elite, the rivalries of services and branches, the geographic deployment and the generational gaps between echelons all must be acknowledged (Janowitz 1966). The illusion of homogeneity about the administrative elite is dispelled when one looks closely (Dogan 1975). Career services give some coherence to relatively autonomous fields, like police, fire, diplomacy and health. But in specific policy domains, clientele elites often dominate the picture (Armstrong 1973).

Especially when talking about elites in rather amorphous fields of endeavour, the implications of structural disjunctions on the perspectives of those in top positions seem far reaching. Most communications elites are set at working odds with one another in the various media where their contacts and skills apply. At community levels, civic leaders rarely sustain close contacts with their counterparts in other localities.

Elites are studied both in context, in what can be called elite characterization work, and out of context, in what is referred to as elite survey work. There are two main genres of the former: those in which elites are characterized by their mission or function, and those in which elites are seen in a custodial capacity, and characterized by the performance of the institutional processes they control. In a corresponding way, elite surveys—in which elites are taken out of context—also have two main genres: those in which the investigator is mainly interested in what elites think, in the acumen, loyalty and ideological bent of mind typical of certain elite perspectives, and those which explore the recruitment of elite figures by looking at the changing opportunity structure, at social credentials, screening criteria, processes of sponsorship, grooming and socialization, and at those who are the gatekeepers, brokers and mentors who affect the *corsus honorum* of a career. In modern systematic survey work, it is customary at the outset to say how, when and where the elite status of those studied has been established, whether by reputation, position held, or process participated in. Interviews are then held, often rather long interviews, to learn their beliefs, perceptions, preferences and appraisals. Necessarily, in survey work, elites are not studied 'in action'.

emotion

William James wrote that he would 'as lief read verbal descriptions of the shapes of the rocks on a New Hampshire farm' as toil again through the classic works on emotion, which lacked a 'central point of view, a deductive or generative principle'. Over one hundred years after James's (1884) famous essay in *Mind,* we are still debating the issues posed by James, in particular the role of physiological changes in emotions, and the central components that determine an emotion. Since James, many theories of emotion and definitions of emotion have been advanced, but there is still a lack of consensus on central issues that preoccupy the emotion area. This diversity of views is due partly to an upsurge during the past two decades of interest in emotion from scholars in different disciplines, all advocating a particular perspective on emotions. In this respect the area of emotion research has changed from a situation in which physiologists and psychologists dominated the field, to a multidisciplinary endeavour in which sociologists and anthropologists are also heavily engaged.

   The issues that preoccupy modern emotion theory are in some respects similar to those that arose from James's theory of emotion. Three major disputes may be distinguished. The first concerns the role of physiological changes in emotion. James advocated what has come to be called a peripheral theory of emotion, in which he argued that the perception of an arousing stimulus causes changes in peripheral organs such as the viscera (heart, lungs, stomach, and so on) and the voluntary muscles, and that emotion is quite simply the perception of these bodily changes. To use James's own example, it is

not that we tremble and run because we are afraid; rather, we are afraid because we tremble and run. This view clearly implies that there should be as many discrete patterns of physiological activity accompanying emotion as there are discernible emotional states. Cannon (1927) published what was widely regarded as a devastating critique of James's theory, although subsequent research has shown that some of Cannon's objections were ill founded. Although Cannon's critique reduced the influence of James's peripheral theory of emotion, this theory has by no means been completely discarded. In particular, the idea that the perception of bodily changes may elicit an emotion still inspires various contemporary researchers. Indeed, there is recent experimental evidence (Laird and Bresler 1992; Strack, Martin and Stepper 1988) that the induction of a mere posture or facial expression may elicit or enhance emotional feelings. However, evidence for the existence of discrete physiological patterns that differentiate the various emotions is still rather weak and this limits the extent to which James's ideas are accepted by modern researchers.

The essence of Cannon's critique was that the visceral changes that occur during emotion are too non-specific to serve as the basis for differentiated emotional experience. This point led later researchers to abandon the search for an explanation of emotion couched exclusively in terms of bodily changes, and to consider more carefully the role played by cognitive factors—the individual's interpretation of external and internal events.

There are several theories that pay attention to cognitive factors, and the question of the precise role played by cognition in emotion is a second major issue in current emotion theory and research. A classic theory is Schachter's (1964) two-factor theory. Schachter reasoned that the mere awareness of bodily changes does not necessarily result in emotional experience: emotion is the joint product of two factors, namely a general state of physiological arousal, and the cognition that this arousal is caused by an emotional stimulus. The arousal creates the condition necessary for any emotion to be experienced, while the cognition determines which emotion is actually experienced. Thus the same physiological arousal could, in principle, be experienced as any of a variety of emotions, depending on cognitive factors. Although this theory has an appealing elegance and simplicity, there is little evidence to support it (Manstead and Wagner 1981). More complex cognitive theories are proposed by Lazarus and his associates (Lazarus and Folkman 1984) and others (e.g. Frijda 1986). They agree that emotions should be seen as temporally extended processes in which cognitions are one of the central components. More specifically, people appraise their circumstances with respect to their well-being, and these appraisals elicit different emotions. This means that different emotions can be distinguished by different appraisal patterns. Indeed, there is abundant evidence that emotions are characterized by different patterns of appraisal. For example, anger is associated with the appraisal of a negative event caused by another person who is held responsible for this, whereas anxiety is characterized by a negative event with an uncertain outcome, and which is mainly situationally caused; guilt is linked to the appraisal of a negative event for which one blames oneself. Although there is consensus about the major dimensions of these appraisal patterns, debates in the early 1990s centred on the question of whether the role of appraisal really is a causal one (Parkinson and Manstead 1992). Much of the empirical evidence does not preclude a different

conclusion, namely that appraisal is the result of the emotion, rather than its cause.

The third major issue governing current emotion research is concerned with its social and cultural aspects. One important question that elicits much theorizing and research is whether emotions are universal or culturally specific phenomena. The advocates of basic emotions (e.g. Ekman 1992) claim that there are a few basic emotions (among others fear, anger, sadness, happiness and disgust) that are expressed in similar ways across cultures and can therefore be recognized universally. Evidence for this claim comes mainly from studies on facial expressions: photographs showing faces posing particular emotional expressions appeared to be correctly recognized by people from a great variety of cultures (Ekman 1982). However, both theoretical and methodological objections have been raised against this view (Russell 1994). The opposite of the basic emotion view is defended by theorists who argue that emotions are simply social constructions. Harré (1986), for example, reasons that in order to gain more insight into emotions, we have merely to study the emotion vocabularies in different cultures. Although there is evidence that the richness, size and content of emotion language differs from one culture to another, there is little support for the view that emotion language is the major determinant of what we feel. However, emotions are influenced by social and cultural factors. Research, much of it conducted by sociologists and cultural anthropologists, has shown how culture socializes our emotions by means of emotion rules, beliefs about emotions, emotion rituals, and so on. Thus, the answer to the question of the cultural-specificity versus universality of emotions seems to lie somewhere in the middle: there are both cross-cultural similarities and differences in emotions. What one finds depends on the level of analysis and the specific aspects of emotions that are taken into account (Mesquita and Frijda 1992).

employment and unemployment

The concepts of employment and unemployment are more easily defined for a developed capitalist economy which has a market for wage labour. Employment is defined as working for at least one hour a week for some payment, either for a wage or for profit, or commission, or without pay in a family business. However, this definition usually excludes people (mainly women) who provide unpaid household services. Unemployment is defined in terms of not being employed, and available and looking for work. In less developed countries (LDCs), where wage labour is not a predominant form of employment, the concept of unemployment becomes fuzzy: the line between employment in the informal sector (selling cigarettes on the street corners) and unemployment is not clearly defined (see Turnham 1993). In most economies people may not look for work when there are no obvious vacancies available and dropout of the labour force (i.e. the participation rate varies). Since the concept of unemployment may not be well defined, labour economists sometimes use the concept of employment-population ratios (or the not-employed to population ratio).

In OECD countries (see OECD 1993), the post-war decades have seen a growth of the service sector and a relative decline of the industrial and agricultural sectors. At the same time there has been a growth in part-time female employment and a decline in full-time male employment. Further, there has been an increase in white-collar employment and a decline in blue-collar employment and wage inequality has increased. After a short period of full employment in the 1950s and 1960s, most of the OECD economies have

faced increasing unemployment and long-term unemployment (the latter defined, at present, as continuous durations of unemployment of twelve months or more). This has led to economists (see Matthews 1968) asking whether the period of the 1950s and 1960s was unusual and whether the norm for developed capitalist economies is of periods of high unemployment. The only OECD countries which appear to have avoided the problems of high unemployment have been Japan, and to a lesser extent the USA. However, the USA appears to have lowered its unemployment rate at the expense of increasing the working poor and creating an underclass, and perhaps, as in LDCs, by a growth of informal sector activities like hustling on the streets.

In conventional economics, employment is determined by demand for labour and supply of labour. Demand for labour is determined in the same way as the demand for non-human inputs (e.g. raw materials, or capital): by firms maximizing profits. Labour supply is determined by individuals maximizing utility choosing between leisure and work (where work is considered to be a necessary evil). In this paradigm wages clear the labour market and unemployment is purely voluntary. In Keynesian and post-Keynesian theories, wages do not adjust instantaneously to clear the labour market and involuntary unemployment eventuates. Employment is determined by labour demand: the excess of labour supply at the market wages is called unemployment.

Full employment is defined as a state where labour demand equals labour supply at existing wage rates. More recently, the concept of the NAIRU has been proposed: this is the non-accelerating inflation rate of unemployment (Johnson and Layard 1986). This level of unemployment, sometimes called the natural rate of unemployment, is often thought of as the full employment level. Many economists argue that the labour market operates in such a way as to make the present level of unemployment depend on the previous history of the time path of unemployment: the idea of *hysteresis* in the labour market which leads to unemployment rates increasing with time in a 'ratchet' fashion. The reasons for hysteresis are thought to be the lower probability of the long-term unemployed finding work because of decreased search by them due to a loss of self-esteem, because of skill atrophy, and employers rejecting them because they see unemployment as a sign of poor qualities. In addition, in the macroeconomic sphere the long-term unemployed have no impact on wage bargaining and the NAIRU increases. In contrast to this view, new classical economists argue that employment and unemployment follow a random path: exogenous shocks simply perturb the natural rate. For the few countries for which we have data spanning a long period (say over fifty years) there is no obvious trend in the unemployment rate (Layard *et al.* 1991).

Unemployment is usually separated into the following components: seasonal, frictional (due to temporary mismatch between workers and vacancies), cyclical (due to aggregate demand changes), and structural (due to long-term changes in the economic structure, including technological change). Sometimes we distinguish hidden unemployment (people who leave the labour force in times of recession) from open unemployment. We also consider underemployment where workers would prefer to work longer hours, e.g. workers who are placed on short-time working, or those who can find only part-time work who would prefer full-time work.

The major explanations of unemployment (and fluctuations in unemployment) are as follows: aggregate demand, technological and structural change, wage rigidity,

information problems, and aggregate supply. More recently, it has been postulated that unemployment in OECD countries has been caused by the growth of low wage Newly Industrialized Countries (NICs, like Korea, Singapore, Thailand, etc.) who are taking away markets from the richer high wage economies (Economist 1994; Krugman and Lawrence 1994).

Keynesians explain unemployment by a lack of aggregate demand for goods and services with a labour market where wages do not adjust instantaneously. Marx and Schumpeter argued that technological and structural change were inherent in a capitalist economy, and, due to the volatility of investment, unemployment would also be cyclical. Marx also argued that the industrial reserve army (unemployment) would act as a brake on wage growth as well as controlling the 'pretensions of the workers' (Junankar 1982). Neoclassical economists explain unemployment in terms of misinformation in the labour market which leads to some unemployed people not accepting wage offers in the (sometimes mistaken) belief that a better wage offer is round the corner. This is made possible by the availability of unemployment benefits. In some versions this is simply an optimizing strategy where the unemployed are carrying out an intertemporal substitution of leisure. In other versions, unemployment is due to random supply shocks. However, it is not explained why these 'random' shocks hit all countries simultaneously.

Most theories of unemployment focus on reasons for wages not adjusting downwards in textbook fashion in the face of excess supply (unemployment). Neo-classical theories tend to emphasize the rigidities introduced by unions, unemployment benefits, and minimum wage legislation. An alternative explanation, the insider-outsider hypothesis, has wage bargaining conducted between employers and unions such that they only concern themselves with the employed labour force (the insiders) while the unemployed (the outsiders) are ignored (Lindbeck 1993).

In the 1980s and 1990s theories of employment and unemployment have focused on emphasizing the distinctive properties of the labour market and the role of wages in providing incentives to offer more or higher quality (more productive) labour services (Solow 1990). Explanations are offered for the wage rate to be determined in such a manner that higher than market clearing wages are set by employers either to get a more skilled labour force (adverse selection models), or to provide the workers with an incentive to be more productive. These efficiency wage models (Akerlof and Yellen 1986) suggest that wages are set higher than necessary and workers who do not perform adequately would be fired (shirking model): the threat of unemployment or a poorly paid job provides workers with an incentive to be productive. In another version, higher wages decrease turnover and hence provide employers with a more stable and hence more productive workforce. In another version, suggested Akerlof, social custom plays a part and a partial gift-exchange takes place: workers get paid a wage higher than necessary and workers provide more (better) labour services than they are required to.

Unemployment imposes severe costs on the economy in terms of lost GDP (both now and in the future), costs to the government in terms of lost revenues, loss of earnings for the unemployed individuals and families, and a loss in terms of physical and mental illness, social disruption, and crime in society Junankar 1986).

Many OECD governments have given up their commitment to full employment, either because they believe that the free market would eventually solve the problem, or that the

danger of inflationary forces is too great to introduce explicit policies for full employment. Recent pronouncements have been in terms of introducing more flexible labour markets (i.e. increased downward flexibility of wages, fewer constraints on employers in hiring and firing practices, weakening of the powers of the unions, etc.). The major policy interventions have been in introducing labour market training programmes, improving the efficiency of labour market exchanges, and deregulating of the labour markets.

energy

Any society's ability to survive depends on its continued access to energy in appropriate quantities and at acceptable costs. The relationship over time between the level of development in an economy and the use of energy is illustrated in Figure 1.

Given this relationship, then the transformation of the world since the 1840s from a world which consisted mainly of peasant economies largely subsistent in their organization to one consisting of post-industrial, industrial and industrializing economies, has produced a global use of energy which is now over twenty-five times greater than it is

estimated to have been in 1860. Figure 2 shows what a remarkably consistent rate of growth in energy use there has been over the whole of this period (at about 2.2 per cent per year), except for the years between 1950 and 1973 when the rate of growth was almost 5 per cent per year.

The demand for energy

Though attitudes to the world energy situation and outlook have been heavily dependent on the idea that this exceptional period of rapid energy growth represents the norm, it was, on the contrary, a unique combination of time-coincident factors which produced an energy growth rate so much higher than the long-term trend; to which (as shown in Figure 2) the world has returned since 1973.

The USA moved on to this flatter part of the curve after 1950 and other industrialized countries after 1973

High

Most western European countries and Japan transferred from points B/B' (high rates of increase in energy use) to point C (lower rates of increase) between 1950 and 1973

Most developing countries have moved on to this sector (A/A') of the curve since the 1950s and may be expected to continue to have high rates of increase in energy demand but note that higher prices have reduced the rates of growth

Energy use

Industrialized countri now have a slow rat of growth in use or a Reduced use of ene with environmental constraints and improved efficiency of energy use under higher price conditio

$\frac{R^e}{R_g} < 1.0$

Low

Very few underdeveloped countries remain on this section of the curve with only low rates of increase in energy use

Pre-industrial period • Period of industrialization • Post-industrial societies
Development over time ⟶

Figure 1 Relationship between energy use and economic development over time: the rate of increase (decrease) in energy use is a function of the stage of economic development. © EGI 1 13/86

Between 1950 and 1973 virtually all the world's nations happened to be on the steepest part of the curve in Figure 1; in a situation, that is, in which their economies were in the most highly energy intensive period of development. First, the rich countries of the western economic system were going through the later stages of the industrialization process with an emphasis on products with high energy inputs—such as motor vehicles, household durable goods and petrochemical products. As a result, the use of energy on the production side of the economy greatly increased. On the consumption side, the

increase in energy use was even more dramatic as a result of the mass use of motor cars, the suburbanization of cities, the switch from public to private transport, the expanded availability of leisure time and the 'annihilation of space' in the public's use of such time, the mechanization of households by the use of electricity-intensive equipment and the achievement of much higher standards of comfort (by heating and/or cooling) in homes and other buildings.
Figure 2 Trends in the evolution of world energy use, 1860 1993
© EGI 144/83 (rev 91)

Second, many of the same factors positively influenced the rate of growth in energy use in the centrally planned economies of the former Soviet Union and eastern Europe. This was particularly the case in respect of those countries' industrialization, with its special emphasis on the rapid expansion of heavy, energy-intensive industry. To a smaller, but, nevertheless, a still significant extent, consumers in the centrally planned economies also increased their levels of energy use as a result of higher living standards and changes in lifestyle. The centrally planned economies were, moreover, extremely inefficient in their use of energy: partly because of technical inefficiencies and partly because the price of energy was kept very low.

Third, in the Third World most countries had moved off the lowest part of the curve shown in Figure 1, as policies of industrialization, accompanied by urbanization, were deliberately pursued in the search for higher living standards. The sort of industry which was established was either energy-intensive heavy industry, such as iron and steel and cement, or relatively energy-intensive industry, such as textiles and household goods. The

urbanization process, moreover, meant that peasants and other rural inhabitants abandoned their low-energy ways of living (in which most of the energy required was collected rather than purchased) for lifestyles in the city environment which were, no matter how poor the living standards achieved, much more demanding in their use of energy.

It was essentially the temporal coincidence of these basic societal change factors in most parts of the world which caused the high rate of growth in energy use in the 1950s and 1960s. The high energy growth rate was, moreover, increased by the continuing decline in the real price of energy during that period. This can be seen in Figure 3 in which the evolution of the real price of Saudi Arabian light crude oil (measured in terms of the 1974 value of the US dollar) over the period from 1950 is illustrated. From this one can see that the value of a barrel of oil fell by almost 60 per cent from 1950 to 1970. This decline brought about a falling market price for other forms of energy during this period throughout the world, and most especially in the western industrial countries with their open—or relatively open—economies. In these areas local energy production (such as coal in western Europe and oil and natural gas in the USA) either had to be reduced in price to enable it to compete, or it went out of business. (This phenomenon was also important for the supply side of the global energy situation. We shall return to this later.) Thus, both the actual decline in the price of energy and the perception created among energy users that energy was cheap, getting cheaper and so hardly worth worrying about in terms of the care and efficiency with which it was used, created conditions in which the careless and wasteful consumption of energy became a hallmark of both technological and behavioural aspects of societal developments—with a consequential emphasis on systems of production, transport and consumption which were, unnecessarily, too energy-intensive.

The impact of higher prices

Post-1970 changes in the price of oil (also shown in Figure 3), and hence in the price of energy overall, brought these attitudes to an end, so that the use of energy has since been curbed. The results of this change have (as shown in Figure 2) been dramatic. The rate of increase between 1973 and 1993 has fallen right back to the historic rate of only 2 per cent per year. The most important element in this reduction in the rate of growth has been the fall in the energy-intensity of economic activities in the industrialized countries. For western European countries, for example, the energy-intensity of economic growth from 1973 to 1982 declined to little more than half that of the preceding ten years, and since 1982 the ratio has fallen by another 20 per cent. There have been both technological and behavioural components in this change; the latter include consumers' decisions to save energy through the expenditure of effort and money on insulating their homes and on living with lower temperatures, and on their more efficient use of their motor cars by driving more carefully and by combining trips to save mileage. It is, however, the technological improvements that have been the more important in saving energy: through more efficient processes in factories, more efficient lighting in offices, the development of motor vehicles, planes and ships which give more kilometres per litre (ton) of fuel, and

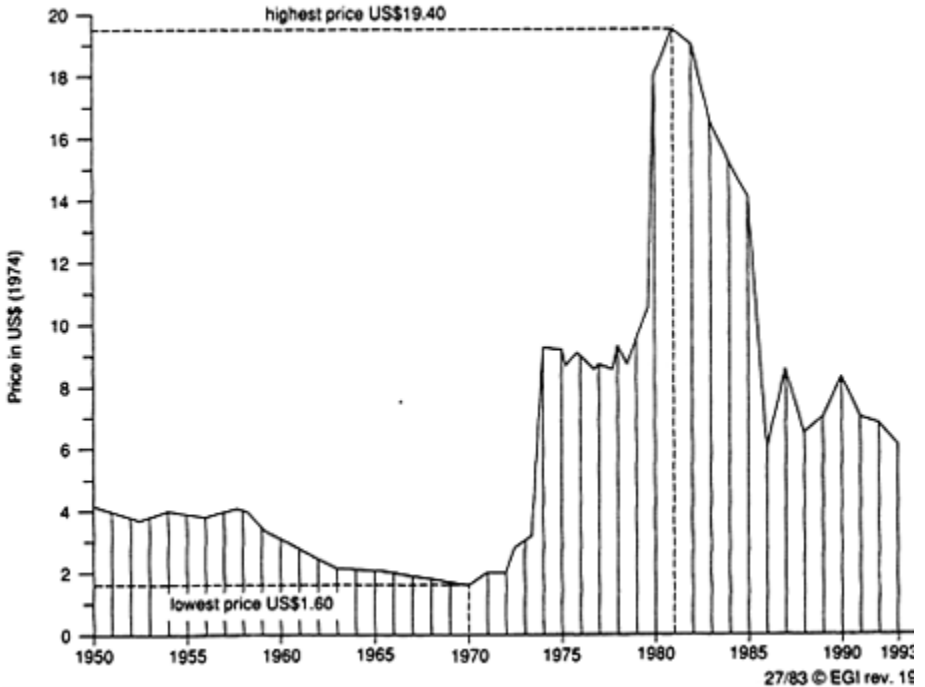
the expansion of inherently more energy efficient systems of electricity production. For example, the production of electricity from natural gas in combined cycle gas turbines is up to 50 per cent more efficient than in conventional power stations. Nevertheless, both


Figure 3 Price of Saudi light crude oil, 1950–93 (shown in 1974 US$ values: the actual price in 1993 was US$16 per barrel)

the behavioural and the technological aspects of more effective energy use still have far to go before the existing energy inefficient systems of the period of low and decreasing-cost energy are finally replaced, even in the richer countries where the required investment funds and other inputs (of knowledge, managerial and technical expertise and so on) are available. The diffusion of more effective energy-using systems to the modern sectors of most Third-World countries is an even slower process because of the scarcity of the inputs involved. Change is, however, taking place under the stimulus of the high foreign exchange cost of energy (particularly oil) imports to the economies concerned. Thus, enhanced levels of energy-use efficiency are being achieved in the Third World. This is an important consideration for the longer-term evolution of global energy demand, as the percentage of world energy use in these countries is steadily increasing under the joint impact of expanding populations and of economies which are going through the most energy intensive period of development (see Figure 1). The countries which had centrally planned economies lie somewhere in between the industrialized and

the Third-World countries in respect of energy use and prospects patterns. To date they have not done as well as the market economies in saving energy, but the importance of energy conservation has now become generally recognized by the post-communist governments of the countries concerned so that the implementation of measures in these countries now has a much higher priority.

The supply of fossil fuels

Meanwhile, on the supply side the search for a higher degree of energy self-sufficiency by nations in all parts of the world became a key element in energy policy making after 1973. This was because of widely shared fears for recurring supply problems, emerging from the dependence on oil from the Middle East and a few other OPEC countries. This caused a reversal of what had hitherto been an increasingly concentrated geography of energy production of post-Second World War period, during which the prolific and extremely low cost oil resources of the Middle East and other areas undermined the economic production of most energy sources in most other parts of the world. Thus, not only did hitherto important energy-producing regions such as western Europe (where the economy had been built on the use of indigenous coal) become dependent on oil imports from the low-cost countries, but so did much of the developing world, where the required rapidly increasing supply of energy was easier to secure on the basis of oil imported through the aegis of the international oil companies than through the efforts to expand the indigenous production of energy. It was only in the case of the few countries, including the USA, which protected their indigenous energy-supply industries to a high enough degree that the contribution of low-cost imported oil was restricted to a relatively small part of total energy supply.

By the early 1970s even the USA, with its wealth of energy resources, finally had to reduce the degree to which it protected its indigenous production in order to reduce the energy cost disadvantage it had come to suffer compared with competing industrial nations, where energy costs were related to the cheap oil available from the Middle East.

This situation changed drastically once OPEC increased the price of oil—as shown in Figure 3. The approximately fivefold real price increase of OPEC oil between 1970 and 1975 and the subsequent further doubling of the price by 1981 removed the economic restraints on investment in locally available energy resources, so there was thus a general reappraisal of the prospects for indigenous energy production in most countries. Some developments were possible in the short term, notably in the USA where underutilized capacity in already established energy-supply industries was quickly brought into production. In western Europe a massive stimulus was given to the efforts to exploit North Sea oil and gas and the hitherto deteriorating prospects for the continent's coal industry were temporarily reversed. Similar developments occurred elsewhere in the non-communist world and produced the changes, shown in Table 1, in the relative importance of OPEC exports to non-OPEC energy demand by 1986.

Table 1 shows how dramatically OPEC's contribution to the non-communist world's energy supply fell. Other oil supplies came to exceed imports of OPEC oil by a very wide margin. OPEC's 1986 oil exports were, moreover, less important than both natural gas

and coal supplies. World energy supplies thus became geographically more dispersed, a process which continued as long as the price of OPEC oil remained so far above the cost of alternatives, and as long as oil supplies from most OPEC countries continued to be perceived as unreliable. In essence, the low-cost, but high-price, oil reserves of the OPEC countries became 'the energy source of last resort'. This involved real economic costs for the world economy as a result of the higher-than-necessary costs of energy inputs to both production and consumption activities—so reducing economic growth in most parts of the world in the 1980s.

Table 1
Sources of energy used in the non-communist world (excluding the OPEC countries) in 1973 and 1986

| | 1973 | | 1986 | |
	mtoe*	*% of total*	*mtoe**	*% of total*
Imports of OPEC oil	1480	36.5	674	16.2
Other energy supplies	2565	63.5	3474	83.8
of which oil	810	20.0	1318	31.8
natural gas	795	19.5	825	20.9
coal	865	20.5	1049	25.3
other	135	3.5	242	5.5
Total	4045	100	4148	100

Sources: Derived from UN Energy Statistics (Series J) and BP's Annual Statistical Review of World Energy.
Note:* mtoe=million tons oil equivalent.

These changes in energy supply and demand conditions soon led, however, to the reversal of the upward trend in prices. This can be seen in Figure 3, which shows a more or less continuing fall in the oil price since 1982. By 1993 the price was, indeed, back to its level of the mid-1970s, yet supplies remained plentiful, while global demand for energy continued to grow only slowly (see Figure 2). Increasing geological knowledge, technical innovations and rising efficiency in production have eliminated the earlier fears of scarcity of fossil fuels and have made the international supply system much more competitive. While there are some residual concerns for the security of supply—largely related to geopolitical factors—a new issue has now emerged to justify continuing concern for energy, that is, the regional and global environmental impacts of the use of increasing volumes of fossil fuels. In particular, the likely global warming consequence of carbon dioxide emissions is now central to policies which seek to constrain energy use, with increases in taxes generally agreed to be the most effective way of achieving this objective. This, of course, implies limitations on the supply required, to the consternation of the countries whose economies depend on fossil fuel exports.

Alternative energy sources

Prospects for the exploitation of renewable energy sources attracted much attention in the
1970s and 1980s through the fears of scarcity of fossil fuels: alternative energy prospects
are now, by contrast, related principally to environmental considerations. Thus, there are
enthusiastic lobbies for the rapid expansion of benign energy systems based on solar,
wind, water, wave and biomass energy potential. There has been an increasingly
significant response to this enthusiasm by energy policy makers in most parts of the
world, mainly in the form of more research and development funds. However, apart from
the continued expansion of hydroelectricity production (a long-established source of
energy), relatively little success has been achieved to date in 'commercializing' the
potential contribution of the benign energy sources. This is partly because of the long
gestation period required for technical innovation, partly because their successful
utilization depends on locating appropriate physical geographical conditions, and partly

because their use also depends on changes in the structure of societies and the reorganization of national energy supply networks. These are formidable problems so that the relative contribution of such sources of energy to the world's now slowly rising total energy needs still seems unlikely to grow very quickly until well into the twenty-first century.

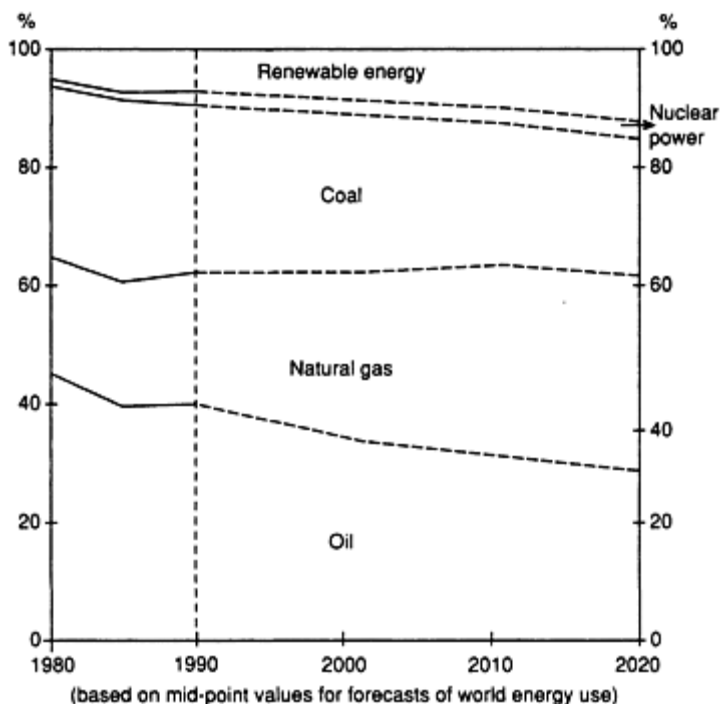
By contrast, nuclear power which initially secured the support of many governments as a means of reducing dependence on imported oil is now also presented as an environmentally cleaner form of energy. Its expansion has thus been generously, even


Figure 5 Percentage contributions of the main sources of energy
to total energy use, 1980 2020 © EGI 62/91

extravagantly, funded (partly, at least, because it was linked to the development of the major powers' nuclear arsenals). There has been a tenfold expansion in nuclear electricity production since the mid-1970s, albeit from a very small initial level of output. In spite of all the efforts and money devoted to it, nuclear power remains globally no more important than water power, and it still contributes less than 2 per cent to the world's total energy use. Some governments and other authorities remain convinced of nuclear power's potential, but cost escalation, public concern for the safety of the reactors and of the irradiated waste products from the power stations, and, most important of all, its inability to compete effectively with electricity from fossil fuels in most countries where nuclear power is a practicable proposition from the standpoints of available finance and

technology have severely undermined the prospects for nuclear power. It, too, seems destined to make little additional contribution to world energy supplies between 1995 and 2015. Figure 4 summarizes the outlook for world energy over the period up to 2020. Growth in use will continue to be modest and in this context the contribution of fossil fuels will remain dominant.

The relative importance of coal, oil and natural gas will, however, change as shown in Figure 5. Plentiful supplies, consumer preference and its more acceptable use from the environmental point of view will eventually make natural gas the world's single most important energy source.

The poor world's energy problem

Outside the framework of the discussion of energy presented here is one element that remains important for large parts of the world, that is, the supply of locally available energy in societies which remain largely or partly subsistent in their economic organization. The *per capita* use of energy in such societies is small (see Figure 1), as it depends on the immediately available supply of combustible materials (such as wood and dung) which can provide for cooking and heating needs. Collectively, however, this pattern of energy use in the world is still large given the numbers of people involved in such societies. Overall, it is estimated still to account for almost 20 per cent of total world energy use, ranging from near zero in the industrialized countries, to about 15 per cent in Latin America and to over 90 per cent in some of the poorest countries of Africa. In almost all of the latter areas the local scarcity of wood is becoming an increasingly difficult problem. The solution requires 'energy-farming' and new, albeit simple, technological developments which bring improved efficiencies in the use of the combustible materials. This is a world energy problem of which little is known and about which even less is being done, compared, that is, with the attention which is given to the problems of oil and the other energy sources required for intensive use in the developed world and in the modernized sectors of the developing countries' economies.

enterprise

see **corporate enterprise; multinational enterprises**

entrepreneurship

The term entrepreneur seems to have been introduced into economic theory by Cantillon (1931 [1755]) and was first accorded prominence by Say (1803). It was variously translated into English as merchant, adventurer or employer, though the precise meaning is the undertaker of a project. John Stuart Mill (1848) popularized the term in Britain.

In the neo-classical theory of the firm, entrepreneurial ability is analogous to a fixed factor endowment because it sets a limit to the efficient size of the firm. The static and passive role of the entrepreneur in the neo-classical theory reflects the theory's emphasis on perfect information—which trivializes management and decision making—and on perfect markets—which do all the co-ordination that is necessary and leave nothing for the entrepreneur.

According to Schumpeter (1934), entrepreneurs are the prime movers in economic development, and their function is to innovate or carry out new combinations. Five types of innovation are distinguished: the introduction of a new good (or an improvement in the quality of an existing good); the introduction of a new method of production; the opening of a new market—in particular an export market in new territory; the 'conquest of a new source of supply of raw materials or half-manufactured goods'; and the creating of a new type of industrial organization—in particular the formation of a trust or some other type of monopoly.

Schumpeter is also very clear about what entrepreneurs are not: they are not inventors, but people who decide to allocate resources to the exploitation of an invention; they are not risk-bearers: risk-bearing is the function of the capitalist who lends funds to the

entrepreneur. Essentially, therefore, Schumpeter's entrepreneur has a managerial or decision-making role.

This view receives qualified support from Hayek (1937) and Kirzner (1973), who emphasize the role of entrepreneurs in acquiring and using information. Entrepreneurs' alertness to profit-opportunities, and their readiness to exploit these through arbitrage-type operations, makes them the key element in the market process. Hayek and Kirzner regard entrepreneurs as responding to change—as reflected in the information they receive—while Schumpeter emphasizes the role of entrepreneurs as a source of change. These two views are not incompatible: a change effected by one entrepreneur may cause spill-over effects, which alter the environment of other entrepreneurs. Hayek and Kirzner do not insist on the novelty of entrepreneurial activity, however, and it is certainly true that a correct decision is not always a decision to innovate; premature innovation may be commercially disastrous. Schumpeter begs the question of whether someone who is the first to evaluate an innovation, but decides (correctly) not to innovate, qualifies as an entrepreneur.

Knight (1921) insists that decision making involves uncertainty. Each business situation is unique, and the relative frequencies of past events cannot be used to evaluate the probabilities of future outcomes. According to Knight, measurable risks can be diversified (or laid off) through insurance markets, but uncertainties cannot. Those who take decisions in highly uncertain environments must bear the full consequences of those decisions themselves. These people are entrepreneurs: they are the owners of businesses and not the salaried managers that make the day-to-day decisions.

Leibenstein (1968) regards the entrepreneur as someone who achieves success by avoiding the inefficiencies to which other people—or the organizations to which they belong—are prone. Leibenstein's approach has the virtue of emphasizing that, in the real world, success is exceptional and failure is the norm.

Casson (1982) defines the entrepreneur as someone who specializes in taking decisions where, because of unequal access to information, different people would opt for different strategies. Casson shows that the evaluation of innovations, as discussed by Schumpeter, and the assessment of arbitrage opportunities, as discussed by Hayek and Kirzner, can be regarded as special cases. Casson also shows that if Knight's emphasis on the uniqueness of business situations is used to establish that differences of opinion are very likely in all business decisions, then the Knightian entrepreneur can be embraced within his definition as well. Because the definition identifies the *Junction* of the entrepreneur, it is possible to use conventional economic concepts to discuss the valuation of entrepreneurial services and many other aspects of the market for entrepreneurs.

Perhaps the aspect of entrepreneurship that has attracted most attention is the motivation of the entrepreneur. Hayek and Kirzner take the Austrian view that the entrepreneur typifies purposeful human action directed towards individualistic ends. Schumpeter, however, refers to the dream and will to found a private dynasty, the will to conquer and the joy of creating, while Weber (1930) emphasizes the Protestant Ethic and the concept of calling, and Redlich (1956) the role of militaristic values in the culture of the entrepreneur. Writers of business biographies have ascribed a whole range of different motives to people whom they describe as entrepreneurs. For many students of business behaviour, it seems that the entrepreneur is simply someone who finds

adventure and personal fulfilment in the world of business. The persistence of this heroic concept suggests that many people do not want a scientific account of the role of the entrepreneur.

Successful entrepreneurship provides an avenue of social advancement that is particularly attractive to people who are denied opportunities elsewhere. This may explain why it is claimed that immigrants, religious minorities and people denied higher education are over-represented among entrepreneurs. Hypotheses of this kind are difficult to test without carefully controlled sampling procedures. The limited evidence available suggests that, in absolute terms, the most common type of entrepreneur is the son of an entrepreneur.

environment

Einstein is reported to have defined environment as 'everything that isn't me'. This aphorism symbolizes one feature of the environmental dilemma. Unlike any other living creature, humans can view the natural world as if they were separate from it. Toynbee (1976) remarked that humans have rational minds and emotional souls. They can order ideas and rank feelings. They can care passionately about salvation and fear for what they bequeath to their offspring. They can overslaughter bison yet create a lasting international

Antarctic sanctuary for whales.

Environment is a metaphor for the enduring contradictions in the human condition: the power of domination yet the obligation of responsibility; the drive for betterment tempered by the sensitivity of humility; the manipulation of nature to improve the chances of survival, yet the universal appeal of sustainable development; the individualism of consumerism and the social solidarity of global citizenship. These points are made in books by Atkinson (1991), Dickens (1992), Dobson (1990), Eckersley (1992) and Sachs (1993). Throughout time, human excesses have been tamed by a combination of pragmatic caution and fearful guilt. The best statement here is Glacken (1967) but more accessible references can be found in Simmons (1989; 1993).

The balancing zone has never been static, nor confined to a single point. More often than not the tension has never been clearly recognized in day-to-day human behaviour. The traditional clash between developers and preservationists that has characterized environmental disputes since the days when the great American naturalist-philosopher John Muir fought to save the Hetch Hetchy valley in the California Yosemite, is no longer the battleground. The real struggle is to reunite humanity with the natural world. That world is resilient beyond anything that humans can do to alter it. But in adjusting to its human-induced transformation, the natural world can and will eliminate much of its meddlers. The tragedy is that those who will suffer are the victims, not the perpetrators of this transformation. Environment is now the process of combining social justice with global survival, of integrating civil rights with natural rights, and of linking all the sciences with the political processes that seek to make democracy work properly.

Humans are beginning to realize how unique life on earth actually is. The cosmos of which we are all a part is the outcome of almost unimaginable chance. The enormously complicated physical, chemical and biological processes that maintain life on earth appear to have a marvellous capacity for self-organization with no apparent ulterior design. This point is best expressed by Lovelock (1992) in the *Gaia thesis.* The biosphere is simply the zone in which life exists on earth. Gaia is defined as a self-regulating system that emerges from the tightly coupled evolution of biota and the material elements and fluxes that circulate substances and energy around the globe. In an important sense, Gaia is a very special scientific concept. It utilizes traditional scientific enquiry to reveal how the totality of physics, chemical and biological process interact to retain the conditions vital for the survival of all life on earth. Gaia has no morality, nor a purpose. It has no special place for humans. The history of evolution is littered with the remains of lost species and the wholesale removal of habitats. If Gaia tells us anything, it is that humans must adapt to survive, and that the process of adjustment is part of the totality of self-regulation. Otherwise the earth will do it for us.

At the heart of environmentalism arc three views of the world, namely technocentric, ecocentric and deep green. First, the *technocentric* mode (O'Riordan 1981) visualizes humanity in manipulate or heroic mould, capable of transforming the earth for the betterment of both people and nature. This is the essence of the progressive conservationists of the turn of the century in the USA (Hays 1959). Technocentrism is optimistic, interventionist, dominant and, for some at least, maleled and hierarchical (Mies and Shiva 1993). It is the product of, and the provider for, conventional science with its bias in favour of objective observation, replicative experimentation, obedience to

laws and hypothesis, and productive use of models. It also thrives on the purported efficiency of market forces, of minimum intervention by the state, and of opportunism in improving individual advancement. Technocentrism is regarded as not only the cause of environmental destitution, but also its salvation (Simon and Kahn 1984). It is seen as the progenitor of environmentally benign technology, environmentally friendly product substitution, and the wealth-creating engine that will allow the poor to be emancipated from their prisons of enforced environmental and social debasement.

The second view is *ecocentric* (Dobson 1990; O'Riordan 1981; Pepper 1986). This is also optimistic, but recognizes the need to incorporate the limits of arrogance in the conduct of human affairs. The aim is to incorporate the costs of altering the natural world, and of removing the civil rights and native knowledge of indigenous peoples by ensuring that these costs and obligations are duly placed on the accounts ledger. This in turn has spawned a host of manipulative middle ground, accommodationist mechanisms aimed at making economic development more socially tolerable and environmentally sustainable. Examples of five of these devices are as follows.

First, *sustainable development,* the buzz phrase of the Brundtland Commission (1987) and the UN Conference on Environment and Development (UNCED) held in Rio de Janeiro in 1992 and the basis of *Agenda 21,* the programme for integrating development and environment: for contrary views see International Union for the Conservation of Nature (1989) and Sachs (1993).

Second, the *precautionary principle,* the up-and-coming concept that accepts that scientific knowledge may never be complete, or ready in time to take justifiable action in anticipation of disaster. Precaution places the spotlight on *civic science,* or the integration of all the conventional sciences within a meaningful democratic process, or *ecological space,* or the provision of room for manoeuvre in the allocation of controls between the developed and developing nations, allowing for the latter to take time to adjust while the former accommodate more quickly and more comprehensively, and on *altering the burden of proof* to ensure that would-be victims can legitimately protest in advance of development so that those who seek to change the status quo must guarantee that no one is actually made worse off (see O'Riordan and Cameron 1994).

Third, *ecological economics,* the incorporation of valuation studies to calculate the worth of environmental services provided by natural systems such as stratospheric ozone or the tropical moist forests, so as to ensure that the full costs of development or of protection of *critical natural capital,* namely the life-sustaining habitats and processes are built into all future economic accounts in the form of parallel *natural resource accounts* or even environmental welfare indices (see Pearce *et al.* 1993).

Fourth, *environmental impact assessment,* or the complete analysis of the full social and natural environmental consequences of both specific projects and the policies upon which they are promoted (O'Riordan and Sewell 1981). This has spawned a whole enterprise of environmental consultancy and is slowly turning the planning, engineering and accountancy professions more environmentally sensitive.

Fifth, *ecoauditing* of industry using techniques such as *life cycle analysis* and *environmental burden analysis.* This is part of the environmental management systems approach to quality assurance in business practice. It is also likely to become internationally standardized as the basis of good corporate commitment to sustainable

development. The various techniques involve systematic recording of the total energy, materials and economic flows associated with products and choice processes organized into comprehensive and public accounts.

All of this is still emerging in the frantic desire to make economic progress environmentally tolerable and socially acceptable. Advocates believe that this is the dynamic zone of ecological adaptation necessary to ensure both wealth creation and human survival. It also recognizes the vital necessity of incorporating all environmental costs, including possible danger to future generations, into the day-to-day behaviour of those alive today. Critics (especially Sachs 1993) regard this as face saving and posturing, allowing business as usual with minor variations to absorb environmentalists and so reinforce its domination under the green trappings of environmental conscience.

Finally, the *deep green* interpretation of environment is profoundly radical both in terms of ethics and social structure. It is sometimes termed *deep ecology* or *steadystate economics* and promotes the cause of small-scale self-reliant and politically empowered communities benefiting from ultra-modern information technology, but essentially running their own affairs on the basis of local resources and local needs. It confronts globalism in the economy and in political dependency, promotes the causes of pacifism, ecofeminism, consumer rights and animal welfare generally, and seeks to emancipate the soul from the oppression of economic and military dependency. Deep ecology is rooted in traditions of anarchism and community empowerment, but it regards the imperative for sustainable development as an opportunity to link social welfare policies, disarmament strategies and peaceful coexistence to create a strategy for collective survival.

environmental economics

Environmental economics has its origins in the writings of Gray (the early 1900s), Pigou (1920s) and Hotelling (1930s), but did not develop as a coherent discipline until the 1970s, the era of the first environmental revolution. There are three central features of environmental economics.

First, human well-being is seriously affected by environmental degradation and the depreciation of natural resources. These linkages can be as obvious as the scarcity of fuelwood because of deforestation, landslides brought about by loss of vegetation cover, and mortality and morbidity due to contaminated water supplies. Or they can be more subtle and complex, as with the effects of certain trace gases on the stratospheric ozone layer and the resulting increase in ultraviolet radiation which affects human health (skin cancers and cataracts) through to marine productivity. That part of environmental economics that deals with demonstrating the *size* of such effects involves *economic valuation,* the process of placing money values on human preferences for, or against, environmental change.

Second, the *causes* of environmental degradation are invariably to be found in the workings, or failures, of the economic system. Such failures generally encompass *market failure,* the inability of free market systems to account adequately for the third party effects of economic activity (externalities); and *intervention failure,* the environmental degradation brought about by government interventions in the working of the economy. Examples of the former include conventional externality situations—such as upstream pollution of a river affecting downstream users—but need to be extended to *global missing markets.* An example of a global missing market is the carbon stored in tropical forests. If the forest is cleared by burning (to convert the land for agricultural use), then the carbon is released as carbon dioxide, contributing to the greenhouse effect and hence global warming. Yet there is no market in carbon storage, so the 'owner' of the forest has no incentive to conserve it to prevent the warming damage. Intervention failures are commonplace, as with the detrimental effects on the environment of the Common Agricultural Policy (e.g. lost hedgerows) and the underpricing of irrigation water, energy and fertilizers in many countries. The underpricing encourages wasteful use and hence creates environmental problems.

Third, the *solutions* to environmental problems are often most efficiently found in correcting the economic causes of degradation. Thus, underpricing of products and resources causes environmental degradation. The solution is therefore to charge the right price by imposing environmental taxes equal to the marginal external costs involved. Ideally, such taxes should equal the marginal externality at the optimum point. In practice, measurement problems result in approximations to such ideal taxes. An alternative to a tax is a *tradeable permit or quota.* These involve issuing quotas for pollution or resource use (e.g. fish catches) equal to the desired level, and then allowing holders of the quotas to buy and sell them. Such markets have emerged in practice for sulphur dioxide permits in the USA, and for fisheries in a number of the world's main fishing grounds. In general, the choice of an *economic instrument* such as a tax or tradeable permit, can be shown to be cheaper, and hence more cost effective, than the alternative command and control regulation.

In the area of natural resource economics, issues such as the optimal rate at which to deplete an exhaustible resource, and the optimal harvest rate for renewable resources have been analysed in great detail. Renewable resource problems probably dominate current work in resource economics due to concerns about overuse of fisheries, deforestation, excess use of groundwater and so on. Indeed, global problems such as ozone layer depletion and global warming can be thought of as renewable resource issues—an excessive use of the world's 'sinks' for everyday pollutants.

In recent years, *sustainable development* has absorbed a lot of attention from environmental economists. Sustainable development involves making sure that economic development paths do not make future generations worse off because of current policies. This non-declining utility definition has been shown by several authors to involve leaving the next generation a capital stock no less than that possessed by the current generation. This constant capital rule has two variants. If all capital is substitutable, then it does not matter if environmental capital (oil, forests, ozone layer) is lost so long as other forms of capital (roads, machinery, education) are built up. This is the weak sustainability rule. If, however, it is not possible to substitute between forms of capital—if, for example, some forms of environmental capital are 'special'—then not only must the overall stock of capital be kept constant but so, too, must the stock of critical environmental capital. In this way sustainable development becomes an added rationale for natural resource conservation.

Finally, the early 1990s witnessed the emergence of *ecological economics,* an as yet ill-defined body of thought that stresses ecological limits to economic activity, the essential nature of environmental assets, and the presence of discontinuities and thresholds in economic-ecological systems.

From being a somewhat fringe activity in the 1970s environmental economics has emerged as one of the most exciting and socially relevant disciplines of the 1990s. It is still a young science, and much more is to come.

epidemiology

Epidemiology is a multidisciplinary enterprise which assesses the causes, natural history and treatment of disease. It originates from the study of epidemics of communicable diseases, but is now much more concerned with chronic disease and health care delivery. The change of emphasis is determined by the relative burden of diseases and consequent expenditure of effort. Essentially the objectives of epidemiology are to minimize the unwanted consequence of diseases by informing appropriate policy to enable them to be prevented, or appropriately and efficiently treated.

Thus epidemiology is primarily the science of the causes of disease. It is concerned to study the variation in incidence of (or mortality from) disease with respect to persons, time and place so that patterns can be observed from which the component parts of a biologically plausible aetiological process can be constructed. This involves statistical methods, social observation and understanding, as well as biological knowledge. Epidemiology forms a basic science for public health, preventive medicine, health services research and health promotion.

In the development of epidemiology key figures have been John Snow (1813–58) who in the nineteenth century removed the handle from the Broad (now Broadwick) Street water pump in Soho, London, and at a stroke discovered the method of transmission of cholera, because people were no longer able to draw up the water, which was contaminated by raw sewage (Snow 1949). Florence Nightingale (1820–1910) was a seminal figure in epidemiology by emphasizing in her practice the importance of systematic observation of patients in order to learn the distinctive features that a disease course took.

Thomas McKeown (1979) identified and discussed the broad determinants of disease and sought to attribute the role of organized medicine in alleviating this burden, which he found to be importantly less than was supposed. Archie Cochrane (1972) took the argument further by identifying the extent of knowledge about outcomes consequent upon treatment, which he argued needed much more rigorous evaluation in medical practice by randomized trials. Richard Doll and Bradford Hill elucidated the relationship of cigarettes with disease by identifying a cohort of willing doctors who answered periodic questions about their smoking habits and enabled rigorous comparison of their

death rates accordingly (Doll and Hill 1964).

Such is the legacy of epidemiology which currently has several branches and factions. Its methods consist of studying and encouraging the improvement of vital statistics on disease incidence and mortality. Sometimes cross-sectional studies are undertaken to look at particular patterns of disease prevalence and population characteristics. More often case control studies are used to investigate the relationships of past exposure to putative risk factors and a disease. Final assessment of causal relationships often has to await prospective cohort studies in which individuals who have been exposed are compared with those who have not. In exceptional circumstances randomized controlled trials are used to compare outcomes between those allocated at random to a particular exposure.

Since epidemiology is almost entirely itself empirical, the development of the subject depends on the amount of variation in disease incidence which is explained by established risk factors. The important theoretical components of epidemiology are largely statistical, social and biological. The statistical provides efficient means of deriving estimates of qualitatively different measures of risk and the biological constrains and informs the epidemiological investigation and their results. The social informs the transfer from discerning risk factors and measuring health to effective health promotion.

In terms of measuring risk, the most useful is the *relative risk.* This measure simply compares the incidence of a disease among groups of subjects exposed to a risk factor with that among those not exposed. Thus the relative risk of lung cancer among heavy cigarette smokers is around twenty, which says that over both genders and all ages, in any country, the annual incidence of lung cancer among heavy smokers is twenty times as high as among similar people who have never smoked. This then gives an indication of the potency of the aetiological effect. Clearly a relative risk of twenty is a good deal more potent than a relative risk of two. This latter might describe the potency of obesity with respect to coronary heart disease or, indeed, environmental tobacco smoke and lung cancer. This number is an aggregated statistic and in circumstances when the relative risk for a risk factor and a disease varies importantly the phenomenon is called *effect modification.* There is no intrinsic reason to suppose constant relative risks across heterogenous populations, but often effect modification is much less important than the aggregate effect itself.

An alternative measure of risk is estimated as the *attributable risk per cent.* This measures the amount of disease which is attributable to the risk factor being considered. Thus it estimates the proportion by which the current overall incidence of lung cancer would decrease if nobody had ever smoked. Thus around 86 per cent of the current incidence of lung cancer is attributable to cigarette smoking. In this respect epidemiology has achieved this degree of understanding, and the policy implication for an individual is importantly informed.

In contrast, another disease, more common among women in most communities than lung cancer, is breast cancer. For this disease the highest determined relative risk is around three, for women with an early age of starting periods, a late age of first pregnancy and a late menopause for instance. The magnitude of the attributable risks depend not only on the relative risks but also on the prevalence of these risk factors. In this case the attributable risk per cents are no higher than 15 per cent for each risk factor, and worse still the risk factors themselves are not readily amenable to incidental change.

Thus as time progresses the role of epidemiology becomes increasingly difficult as the larger effects are found and validated. The smaller effects of relative risks of around 1.5 are exceptionally difficult to establish epidemiologically because of measurement errors and the problem of confounding, where an association is observed which cannot be distinguished between an association with an unknown risk factor or a direct causal relationship.

However, these small effects are of paramount importance for common diseases because they represent the rule and not the exception and offer the greatest hope for the prevention of disease not amenable to treatment. Since most chronic diseases are not particularly amenable to treatment, progress must happen by constructive synergy between epidemiology with statistics, the social sciences and biology. Thus new genes which predispose to cancer, for incidence, will give rise to more precise estimates of other risks in new epidemiological studies.

equality

'We hold', wrote Thomas Jefferson (1747–1826), 'these truths to be sacred and undeniable; that all men are created equal and independent'. No natural scientist *qua* scientist could do other than dismiss such a statement as either meaningless or empirically false. Equality for a mathematician is a concept of some complexity in relation, for example, to identity or correlation, but one of no moral significance. Social scientists by contrast are latecomers to a debate about equality which is unresolved because it adds to the mathematician's complexity the further complications of moral

argument. Equality refers to the principles on which human society ought to, as well as might, be based. Jefferson's was a moral declaration, not an empirical description. Social science attempts to explore the empirical validity of such declarations. The question is whether, and in what sense, social, political and economic equalities are possible. The answer is tentative, requiring the determination of the origins of inequality, the significance of inequality, and the viability of action intended to establish equality. All three aspects are disputed.

Traditional discussion of the origins of inequality turned on a crude distinction between nature and society. Modern recognition of cultural evolution complicates that distinction and tends to substitute a more elaborate matrix out of the consequences of interaction between genetic and environmental influences. But in neither simple nor sophisticated discussion is there denial of natural inequalities, the Jeffersonian declaration notwithstanding. Humans are not clones, and Mendelian genetics guarantees variation. Dispute, however, continues in important areas of scientific ignorance. For example, there is not adequate scientific evidence to settle the dispute between those who believe in the genetic basis of differences between ethnic or racial or class groups in educational attainment or performance in intelligence tests, and those who hold such differences to be socially created. Resolution of such disputes is, in principle, possible through the further advance of empirically tested theories of the interaction between heredity and environment.

Meanwhile dispute about the significance of natural differences continues its long history. Plato confidently argued from natural to political inequality. Hobbes in *Leviathan* (1934 [1651]) expressed the opposite view:

> Nature hath made man so equall, in the faculties of body, and mind; as that though bee found one man sometimes manifestly stronger in body, or of quicker mind than another; yet when all is reckoned together, the difference between man, and man, is not so considerable, as that one man can thereupon claim to himself and benefit, to which another may not pretend, as well as he.

Hobbes's formulation still defines the debate. Egalitarian claims, especially with respect to race and gender, are more strident now than they were in the seventeenth century, and we would now say that Hobbes was making empirical propositions from both genetics and sociology, the one referring to natural differences and the other (about claiming and pretending) referring to the social psychology of human perceptions of social rights. But the central assertion is fundamentally about the values which ought to be reflected in the actual relations of men and women in society.

In this sense the debate, turning as it does on ethical priorities between such values as equality, liberty and fraternity, may never be finally resolvable. There have been, to be sure, notable contributions to greater conceptual clarity as to the meaning of terms. John Rawls (1971) adopts the device of the 'original position'—an 'if so' story of the rational choices that might be expected from an individual contemplating different societies with known different equalities or inequalities of positions but an unknown placement for the contemplator—to illuminate the problems of value choice. Brian Barry (1973) takes the discussion further to demonstrate how a small adjustment to Rawls's social and

psychological assumptions opens the possibility of a crucial shift of preference towards egalitarian rather than liberal forms of society. But no amount of conceptual clarification, sophisticated or erudite, solves the problem of evaluation.

The social sciences can, however, note the provenance of different priorities. One mundane but momentous perspective recurs down the ages—the recognition of mortality. Thus Horace (BC 65–8) wrote: 'Pale death kicks his way equally into the cottages of the poor and the castles of kings.' And James Shirley (1596–1666) reminds us that

> Death lays his icy hand on kings
> Sceptre and crown
> Must tumble down
> And in the dust be equal made
> With the poor crooked scythe and spade.

This attitude is integral to Christian social teaching, which dominated the evaluation of equality at least until the eighteenth century. It was not that natural inequalities between individuals were denied so much as deemed irrelevant in discussing the rights and wrongs of dictatorship or democracy, freedom or slavery. Christians were not only 'equal before the Cross' but, as the early Church Fathers insisted, would, if they eschewed sin, live like brothers without inequalities of property and power. Sin, since the fall of Adam, had created earthly inequality. Political inequality might be necessary to protect order and restrain evil, but it did not arise, as Plato had imagined, from natural inequality. Political inequality in Christian tradition must be endured but by no means implied a necessary respect or admiration for the rich and the powerful. On the contrary, position in the next world was typically held to be threatened by privilege in this. 'He hath put down the mighty from their seat and hath exalted the humble and meek,' says the Magnificat.

The break with Christian attitudes of submission to inequality dates from the eighteenth century, with the decline of religious belief and the beginnings of a secular optimism with respect to the possibility of social transformation. Egalitarianism as a movement is commonly associated with Rousseau. But Rousseau, though believing that the evils of unfreedom and inequality were socially created, was a remorseless pessimist. He held that freedom was impossible except in a community of equals, but held out no hope of social transformation towards equality. In this sense he was a child of Christianity, and if the early socialists (Fourier, Proudhon, Saint-Simon, Robert Owen, William Thompson) were his intellectual children they were also crucially different in entertaining the hope of progress. Modern egalitarianism derives from this form of sociological optimism, and it was encouraged by, if by no means identical with, either the Hegelian idealist or Marxist materialist theories of the inevitability of social transformation. Hegel's elaborate analysis of the relation between masters and slaves, and Marx's development of it into a prediction of the future history of the working class hold out the possibility of a community of equals.

However, egalitarianism does not presuppose either the Hegelian or the Marxist theory of history. Its more fruitful contemporary discussion in the social sciences proceeds on assumptions of openness or voluntarism as opposed to necessitous history. These debates

are the substance of the third aspect of the equality problem—the viability of deliberate social action aimed at reducing inequality. One theoretical approach deserves mention here because it avoids both liberal evolutionist determinism and the alternative Marxist historicism. This is T.H.Marshall's (1950) interpretation of the development of citizenship in advanced industrial societies. Marshall shows in the case of Britain how the basic equality of membership in a society, which is rooted in the civil rights established in the eighteenth century, was extended to include political rights in the nineteenth century and certain social rights in the twentieth century, when citizenship and class have been at war as opposing principles of social distribution. Marshall's analysis also brings out the important truth that the forces which influence the distribution of life-chances are neither mechanical nor irreversible. Class displaced feudal status with formal equality of market relations, as well as ushering in new inequalities of social condition. Citizenship promotes unequal rewards as well as equal rights, for example, state scholarships to selective university admission and universal political franchise. More generally, it may be noted that no social goal, equality, efficiency, liberty, order or fraternity may be regarded as absolute. Public policies are perforce compromises aiming at optimal balance between desired ends.

Three illustrations of the limits to egalitarianism are prominent in the form of arguments against the viability of egalitarian theory.

The first illustration concerns the immutability of occupational hierarchy, postulating a *de facto* necessity for some jobs to be more distasteful, unrewarding and injurious to health than others. Given that life-chances are largely determined by the individual's occupation, a hierarchy of social advantage seems to be inescapable, and equality, as opposed to equality of opportunity, therefore unobtainable. But, egalitarians reply, a less inegalitarian society is not sociologically impossible. It is not difficult to imagine a wide range of counteracting social policies. Apart from progressive taxation and levies on wealth, there could be national service specifically designed to direct the advantaged to a period of distasteful labour. The obvious rejoinders are lodged in the name of liberty and economic efficiency, again emphasizing the relativist character of claims for any social principle. Value choice is always the nub of the issue.

A second illustration may be had from Christopher Jencks's *Inequality* (1972) which essentially argues the importance of educational reform as an instrument of egalitarianism and stresses the role of chance or luck in the unequal distribution of income and occupational status. Schooling explains only 12 per cent of the variance in US incomes. But Jencks's argument is flawed in that his evidence is about the distribution of individuals over a given structure of occupations and wages. The explanation of inequality of income accruing to jobs is not what would explain who happens to hold those jobs. Whether the inequality of the job structure is immutable remains an open question.

Finally, there is the alleged obstacle of genetic differences between races and classes of which Jensen (1972) has been an outstanding proponent. As to classes, and against Jensen's marshalling of the evidence from studies of twins reared apart, there is the opposed conclusion of Schiff (1982) from his studies of cross-class adopted children in France. As to race, it has to be said that we do not yet have the techniques or the data to measure definitively the genetic and environmental influences on race-IQ differences.

Nor does the answer really matter, for there are more important issues of equality and justice in present-day society which do not have to wait upon further advances in the social sciences.

equilibrium

In a static context, two distinct but related definitions of equilibrium can be given. The first defines equilibrium as a position of balance in the economy; the equality of demand and supply is an equilibrium under this definition because the forces of supply are balanced by the forces of demand. Alternatively, equilibrium can be defined as being achieved when no agent in the economy has any incentive to modify their chosen action or chosen strategy. This latter definition is derived from that used in the theory of games and is illustrated by the equilibrium of an oligopolistic market in which all firms are satisfied with their choice of output level. It is easily seen that these definitions are related. When supply is equal to demand, it is also true that no firm will wish to produce any more or less since each will have sold its profit-maximizing quantity. Similarly, each consumer will have been able to carry out their chosen consumption plan and this will be utility-maximizing. In the context of a competitive economy, the two definitions are identical: as shown by Arrow and Debreu (1954), the equilibrium of the competitive economy can be represented as the equilibrium point of a suitably defined game. For

dynamic economies, the tradition since Hicks (1946) has been to divide time into discrete periods. When markets are balanced within a period, a temporary equilibrium is achieved. An equilibrium for the economy is a sequence of temporary equilibria.

Despite the existence of research into the economics of disequilibrium, the concept of equilibrium remains at the heart of economic analysis. Much effort is directed towards proving the existence of equilibrium in economic models and demonstrating the welfare properties of equilibrium. Equally important are the analysis of the uniqueness and stability of equilibrium and the determination of how changes in exogenous parameters affect the equilibrium. Positions of equilibrium are also contrasted to those of disequilibrium.

This emphasis upon equilibrium can be given several explanations. Historically, the economy was viewed as self-correcting so that, if it were ever away from equilibrium, forces existed that move it back towards equilibrium. In the long run, equilibrium would then always be attained. Although such adjustment can be justified in simple single-market contexts, both the practical experience of sustained high levels of unemployment and the theoretical study of stability (Arrow and Hahn 1971) have shown that it is not justified more generally The present justifications for focusing upon equilibrium are more pragmatic. The analysis of a model must begin somewhere, and the equilibrium has much merit as a starting point. Sometimes the focus can be justified by showing that the equilibrium is the outcome of playing the underlying game correctly. In addition, even if the final focus is on disequilibrium, there is much to be gained from comparing the properties of points of disequilibrium to those of equilibrium. Finally, no positions other than those of equilibrium have any obvious claim to prominence.

ethics in social research

Social research ethics involve the consideration of the moral implications of social science enquiry. Ethics is a matter of principled sensitivity to the rights of others, in such a way that human beings who are being studied by social scientists are treated as ends rather than as means. Such ethical issues frequently also lead to consideration of the politics of research, the place of the investigator in the power structure, and the wider social impact of research. Those conducting social research need increasingly to be aware of the ethical and political implications of their actions.

The protection of human subjects is enshrined in the doctrine of informed consent, first developed in biomedical research. This stipulates that the voluntary consent of the human subject is essential, and this should be freely given without duress, and knowing and understanding what the research involves. Most social research, whether by experimental, social survey or observational methods, respects this principle, but there have been occasional sharp controversies where experimental or observational subjects have been left in ignorance of research, or have had research misrepresented to them. In observing the principle, most social scientists do not follow the formal procedures used in medical research such as signed consent forms.

A related controversy has concerned the use of deception in social research. The majority of social scientists are open about their purposes and aims, but in rare cases deception has been used on the grounds that, because of practical methodological or moral considerations, research could not otherwise be carried out. (Such studies include research on obedience to authority, and sexual deviance.) Objections to deception include its degrading and false character, its harmful social consequences, harm to the investigator, the creation of suspicion among subjects, and the breach of informed consent.

Research may in certain circumstances impinge upon the privacy of research subjects (that is, the freedom of the individual to decide how much of the self to reveal to others, when and to whom). Some information about the individual may be sensitive. Some settings (for example, jury rooms, Cabinet meetings) may be entirely closed to outsiders. The wider dissemination of research results may affect subjects adversely. Such problems may be handled by obtaining informed consent or by various forms of making data anonymous. In the latter case, for example, the location in which research was carried out may be concealed and the identities of particular individuals hidden under pseudonyms. A distinction may be made between the circumstances under which data are collected, and their subsequent storage, dissemination, analysis and re-analysis. Issues of confidentiality are raised by the latter, though also impinging upon collection. What will happen to data once collected? To whom will they be available? What repercussions might there be for the individual in providing certain data to a social researcher?

The importance of these questions has been intensified by the advent of the electronic computer, with immensely powerful means of large-scale data storage and retrieval. This

has a major impact upon census data and large-scale social survey data. Various techniques have been developed to ensure that individual identities cannot be linked to published information. These include the deletion of individual identifiers such as name, address or local area of residence; the suppression of tables containing small numbers of cases; and processes of random error injection. In addition to physical security, technical means exist for making anonymous the data held in computer files, including the separation of identifiers from the main body of data and their linkage by suitable codes. Randomized response is a method of ensuring the confidentiality of data while it is being collected.

The ethical issues raised by research go wider than the treatment of research subjects and handling of data once collected. The social impact of research has been of concern and controversy both within particular societies (as in the Moynihan Report on black families in the USA) and internationally (as in Project Camelot in Chile in the 1960s). There is increasing concern about the sponsorship of research (Who pays? For whom, and in whose interest, is research conducted?), the negotiation of research access (especially the role played by gatekeepers, who may give or withhold permission), and about the possible adverse effects of the publication of research results on certain weaker groups or lower status sections of society. The investigator can rarely control any of these factors, but awareness of them can help to produce more effective work. Particular care is also required to review the ethical implications of action research and applied research leading to social intervention (for example, of some of the large-scale social experiments for social policy). Consideration of these broader issues leads on to an examination of the political role of social science research and its place in the society in which it is carried out.

There is no agreed theory of research ethics with which to evaluate the merits of undertaking particular pieces of research. It is difficult to determine whether, and if so to what extent, research subjects may be harmed by particular research practices. One widespread approach is in terms of a utilitarian risk/benefit calculus, but this leaves several issues unresolved. Both risks and benefits are difficult to predict and to measure, harm to the individual can only with difficulty be weighted against societal benefits, and the investigator is usually the judge in his own case. Another approach is in terms of situational ethics, where the investigator weighs up the morally appropriate course of action in the actual research context. A different approach is in terms of absolute moral principles to be followed in all situations. No approach receives universal approval, and ethical decision making in research remains ultimately a matter of individual judgement as well as professional controversy.

One practical consequence both of the societal impact of research and the indeterminacy of ethical decision making about research has been a move toward greater regulation. Many professional associations of social scientists have their own ethical codes, to which members are expected to adhere. Various forms of peer review by a researcher's own department or institution are a more rigorous and direct form of oversight. The Institutional Review Boards established by universities in the USA are one example of efforts to prevent unethical behaviour by social researchers.

ethnic politics

More than 80 per cent of contemporary states that comprise the United Nations are ethnically plural, in that they contain two or more mobilized ethnic communities. These communities compete, sometimes by civic methods, sometimes by violence for hegemony (control of the state apparatus), for autonomy (ranging from regional self-government to secession), or for incorporation into the society and polity on more favourable terms. Inter-ethnic relations may vary from stratificational (one group dominating the others politically and economically), to segmentational (each party controlling significant resources and institutions). In the contemporary era, ethnic politics implicate the state, because the state has become the principal allocator of the values that affect the relative power, status, material welfare, and life-chances of ethnic collectivities and their individual constituents. The values at stake may be political—control of territory, citizenship, voting rights, eligibility for public office and the symbols of the state; economic—access to higher education, employment, land, capital, credit and business opportunities; or cultural—the position of religion, the relative status of language in education and in government transactions.

Ethnic politics may be generated by the grievances of territorially concentrated peoples, demanding greater autonomy for their homeland and more equitable representation in the central government; or by immigrant diasporas asking for more equitable terms of inclusion in the polity, combined often with claims for recognition and official support for their distinctive cultural institutions. These initiatives often trigger counter-mobilization in the interest of ethnic groups that feel threatened by these claims and by state authorities committed to the ethnic status quo.

The latter have the principal responsibility for managing or regulating ethnic conflicts. Their strategies may be directed in three ways: first, at maintaining pluralism by coercive domination of subordinated ethnic communities or by consensual processes such as federalism and power sharing; second, at eliminating pluralism by genocide, expulsion or induced assimilation; or third, at reducing the political salience of ethnic solidarity by cultivating crosscutting affiliations, delegitimizing ethnic organizations and ethnic political messages, and emphasizing individual participation in the economy and polity. Ethnic conflicts are seldom settled or resolved; though specific issues may be successfully compromised, the parties remain to focus their grievances and demands on

other issues. Thus ethnic politics is a continuing feature of ethnically divided states.

Government policies may contribute to stimulating and rewarding ethnic mobilization, as well as to mitigating ethnic conflict. Complicating inter-ethnic relations is the inevitability of factions within ethnic communities, each competing for available resources, for support within their constituency, and for the right to represent it to outsiders. Factional conflicts within ethnic communities may result in expedient, often tacit, understandings and coalitions with counterparts across hostile ethnic boundaries or with representatives of the state.

Many ethnic disputes spill over the borders of individual states, especially where ethnic kinfolk inhabit neighbouring states. Domestic ethnic conflicts thus intrude into international relations, prompting intervention by other states, by sympathizers with one of the parties to the dispute, and by international organizations attempting to mediate, restore and maintain order or mitigate the suffering of civilians and refugees. With the termination of the Cold War, violent ethnic conflicts including full-scale civil wars have emerged as a major source of international instability that preoccupies national politicians and attentive publics; they have overwhelmed the diplomatic, financial and operational capacities of the United Nations.

Liberals, Marxists and modernizers, despite their differences, have joined in perceiving ethnic solidarity as the residue of earlier stages of human development and in predicting and advocating its early disappearance in favour of more rational forms of association. They continue to treat it as a dangerous and essentially illegitimate phenomenon. Others explain the resurgence of politicized ethnicity and thus ethnic politics variously as, first, the search for community in increasingly bureaucratized and impersonal industrialized societies; second, more reliable sources of security and material opportunity than class-based organizations or weak, unrepresentative Third-World governments; third, efficient vehicles for mobilization and representation of individual and collective interests in modern societies; or fourth, the consequence of the disintegration of colonial empires and multi-ethnic states that leave ethnic collectivities as their residual legatees. These explanations relate to an ongoing dispute between 'primordialists', who argue that collective ethnic identies are deeply-rooted historical continuities nurtured by early socialization and reinforced by collective sanctions, and 'instrumentalists', who hold that ethnic identities and solidarities are fluid, pragmatic and opportunistic, often constructed by ethnic entrepreneurs to justify demands for political and especially material advantages.

Self-determination is the ideology that legitimizes ethnic activism on behalf of peoples who demand independence or increased territorial autonomy. Multiculturalism justifies demands for institutional separation and self-management where territorial autonomy is not feasible. Demands for non-discriminatory inclusion which may run parallel to cultural pluralism are inspired by universalistic liberal principles. State nationalism may either confirm the superordinate position of a dominant ethnic community or claim a higher order allegiance to the state that amalgamates and supersedes constituent loyalties in an ethnically plural society.

ethnicity

Ethnicity is a fundamental category of social organization which is based on membership defined by a sense of common historical origins and which may also include shared culture, religion or language. It is to be distinguished from kinship in so far as kinship depends on biological inheritance. The term is derived from the Greek noun *ethnos,* which may be translated as 'a people or nation'. One of the most influential definitions of ethnicity can be found in Max Weber's *Economy and Society* (1968 [1922]) where he describes ethnic groups as 'human groups (other than kinship groups) which cherish a belief in their common origins of such a kind that it provides a basis for the creation of a community'.

The difficulty in reaching a precise definition of the term is reflected in the many different words employed in the literature to describe related or similar concepts, such as race and nation. While usage varies, 'race', like kinship, has biological connotations, although these are frequently without foundation, and nation implies a political agenda— the goal of separate statehood beyond that generally associated with ethnic groups. According to Weber (1968 [1922]), 'a nation is the political extension of the ethnic community as its members and leadership search for a unique political structure by establishing an independent state'.

In predominantly immigrant societies, like the USA, Argentina, Australia and Canada, the study of ethnic groups forms a central theme of their social, economic and political life. Systematic research on American ethnic groups can be traced to the sociologists of the Chicago School during the 1920s, led by W.I.Thomas and Robert Ezra Park (Lal 1990), who were concerned with the processes of ethnic group assimilation into the dominant white, Anglo-Saxon, Protestant (WASP) mainstream. Park's 'race relations cycle', outlining a sequence of stages consisting of 'contact, competition, accommodation and assimilation', implied that successive ethnic groups would be absorbed into a relatively homogeneous US society. The underlying assumption of ethnic group theory was that a gradual process would result in the disappearance of separate ethnic groups

into an American melting pot.

This unilinear interpretation gave way to more pluralistic conceptions of ethnicity in the USA, in which various dimensions of assimilation were identified by sociologists like Milton Gordon (1964). Gordon distinguished between cultural assimilation (acculturation) and structural assimilation, the former signifying the adoption of the language, values and ideals of the dominant society, while the latter reflected the incorporation of ethnic groups into the institutions of mainstream society. While cultural assimilation did not necessarily result in an ethnic group's inclusion within the principal institutions of society, structural assimilation invariably meant that assimilation on all other dimensions—from personal identification to intermarriage—had already taken place.

This conceptualization contrasts with that of M.G. Smith (1987), who argued that the key issue involved in a general theory of ethnic relations was the differential incorporation of ethnic groups into larger social units. Smith distinguished between three types of social incorporation: the *universalistic* type, where individuals are incorporated directly and on identical conditions in a common society; the *differential* mode, which is the same process except that individuals are incorporated on an unequal basis, either in a superior or inferior position; and *segmental* incorporation, where ethnic groups are incorporated in a common society 'as units of equivalent status on identical terms'. In this third case, individuals are incorporated indirectly, either on an egalitarian or unequal basis, giving a variety of possible ethnic outcomes.

Scholarly concern with ethnicity and ethnic groups has become increasingly salient since the 1960s. Faced with the proliferation of separatist movements throughout the world, and the rise of the so-called 'unmeltable ethnics' in North America, the inadequate assumptions underlying theories of modernization have been exposed in all types of societies, whether they are in the capitalist, socialist or developing world. The notion that modernity would result in a smooth transition from *gemeinschaft* (community) to *gesellschaft* (association), with the gradual dissolution of ethnic affiliations, simply did not fit the facts. Some social scientists argued that there was a primordial basis to ethnic attachments (Geertz 1963), while others explained the apparent persistence of ethnicity in largely instrumental terms, as a political resource to be mobilized in appropriate situations (Glazer and Moynihan 1975). Not only has ethnic loyalty taken on new meaning in many industrial societies (Esman 1977), but also ethnic divisions have continued to frustrate the efforts of nation-building in most post-colonial societies. Even the countries of the Communist bloc could contain the ethnic demands of their multinational, subject populations only by a judicious blend of co-optation and political oppression (Connor 1984; 1994).

The focus of research on ethnicity has shifted away from studies of specific groups to the broad processes of ethnogenesis, the construction and perpetuation of ethnic boundaries, and the meaning of ethnic identity. The question of the ethnic origin of nations (A.Smith 1986) has produced the same tension between those who stress the continuity of ethnic history and others who emphasize its situational nature. While most social scientists recognize the flexibility of ethnic identification, that under certain circumstances ethnicity becomes salient whereas in others it remains a dormant capacity waiting to be mobilized, some take the position that its impact has been greatly

exaggerated. It is often merely 'symbolic ethnicity' (Gans 1979), or its influence is largely an illusion based on the 'invention of tradition' (Hobsbawm and Ranger 1983) to serve the interests of ethnic political entrepreneurs or, in the neo-Marxist literature, the ruling class.

One of the most influential writers on ethnic boundaries has been the anthropologist Fredrik Barth (1969), whose stress on the processes of group inclusion and exclusion can be seen as a parallel development to the sociological insights of Max Weber. Weber pointed to the tendency of social groups to attempt to monopolize wealth, prestige and political power by systematically excluding outsiders from achieving membership. Immigration restrictions are one way this can be attempted in modern societies. Another is the manner in which citizenship is defined by the state, so that in the case of Germany, for example, the dominant principle reflects a sense of shared ancestry, *jus sanguinis,* while in France the critical factor has been residence, *jus soli* (Brubaker 1992). While some writers have stressed the voluntary nature of ethnic group membership and the variety of ethnic options available to individuals in many post-industrial societies (Waters 1990), others point to the coercive element to be found in all forms of ethnic stratification that can be viewed as more crucial in most situations than any hypothetical elements of preference and choice (Jenkins 1994).

A central concern of social scientists has been the attempt to understand the nature of ethnic conflict and violence. Few issues have been of greater practical importance as the post-Cold War era has been marked by a resurgence of ethnic warfare and genocide in societies as diverse, and remote from each other, as Bosnia and Rwanda. In other societies, like South Africa, a relatively peaceful transfer of power in the elections of April 1994, from a white minority to the black majority, rests on a volatile sub-structure of ethnic divisions and fragile compromises (Adam and Moodley 1993).

A wide variety of theoretical perspectives can be found supporting contemporary studies of ethnicity and ethnic conflict (Rex and Mason 1986). Some, like rational choice theory, are methodologically individualistic and apply a cost-benefit formula to account for ethnic preferences and to explain the dynamics of ethnic group formation. These have been criticized on the grounds that they fail to appreciate the collective dynamics of much ethnic behaviour and underestimate the irrational side of ethnic violence. Other common perspectives focus on ethnic stratification: neo-Marxist theories stress the economic components underlying much ethnic discrimination; while those following in the tradition of scholars like Weber and Furnivall provide a more pluralistic interpretation of differences in ethnic power. In general, these originate from conquest and migration, and are used to account for the hierarchical ordering of ethnic and racial groups. Further theories point to psychological factors, like prejudice and ethnocentrism, as important explanations for the persistence of ethnicity. Two highly controversial arguments centre on genetic imperatives, which operate through the mechanism of kin-selection, and form part of the application of sociobiological thinking to ethnic relations; and neo-conservative theories that concentrate attention on cultural characteristics, which (it is asserted) are disproportionately distributed among certain ethnic groups (Sowell 1994; van den Berghe 1990). Such theories have been vigorously challenged because of their deterministic implications. The heat of the debate reinforces the conclusion that no one theory provides a generally accepted and comprehensive paradigm to explain the

complexity of ethnic group formation or the persistence of ethnic conflict in the world today.

ethnography

Ethnography is a term that carries several historically situated meanings. In its most general sense, the term refers to a study of the culture that a given group of people more

or less share. The term is double-edged and has implications for both the method of study and the result of such study. When used as a method, ethnography typically refers to fieldwork (alternatively, participant-observation) conducted by a single investigator who 'lives with and lives like' those who are studied, usually for a year or more. When used as a result, ethnography ordinarily refers to the written representation of a culture. Contemporary students of culture emphasize the latter usage and thus look to define ethnography in terms of its topical, stylistic and rhetorical features.

There are three moments (discernible activity phases) associated with ethnography. The first moment concerns the collection of information or data on a specified culture. The second refers to the construction of an ethnographic report; in particular, the compositional practices used by an ethnographer to fashion a cultural portrait. The third moment of ethnography deals with the reading and reception that an ethnography receives across relevant audience segments both narrow and broad. Each phase raises distinctive issues.

The greatest attention in the social sciences has been directed to the first moment of ethnography—fieldwork. This form of social research is both a product of and a reaction to the cultural studies of the mid- to late nineteenth century (Stocking 1987; 1992). Early ethnography is marked by considerable distance between the researcher and researched. The anthropologists of the day based their cultural representations not on firsthand study but on their readings of documents, reports and letters originating from colonial administrators, members of scientific expeditions, missionaries, adventurers and, perhaps most importantly, faraway correspondents guided by questions posed by their stay-at-home pen-pals. Not until the early twentieth century did ethnographers begin to enter, experience and stay for more than brief periods of time in the strange (to them) social worlds about which they wrote. Bronislaw Malinowski (1922:1–25) is most often credited with initiating by example a modern form of fieldwork that requires of the ethnographer the sustained, intimate and personal acquaintance with 'what the natives say and do'.

There is, however, a good deal of variation in terms of just what activities are involved in fieldwork and, more critically, just how such activities result in a written depiction of culture. Current practices include intensive interviewing, count-and-classify survey work, participation in everyday routines or occasional ceremonies engaged in by those studied, the collecting of samples of native behaviour across a range of social situations, and so on. There is now a rather large literature designed to help novice or veteran fieldworkers carry out ethnographic research (e.g. Bernard 1994; Hammersley and Atkinson 1983; Spradley 1979).

Yet much of the advise offered in fieldwork manuals defies codification and lacks the consensual approval of those who produce ethnographies. Fieldnotes, for example, are more or less *de rigueur* in terms of documenting what is learned in the field but there is little agreement as to what a standard fieldnote—much less a collection of fieldnotes—might be (Sanjek 1990). Moreover, how one moves from a period of lengthy *in situ* study to a written account presumably based on such study is by no means clear. Despite seventy or so years of practice, fieldwork remains a sprawling and quite diverse activity (Kuper 1983).

The second moment of ethnography—writing it up—has by and large been organized

by a genre labelled 'ethnographic realism' (Clifford and Marcus 1986; Van Maanen 1988). It is a genre that has itself shifted over time from a relatively unreflective, closed and general (holistic) description of native sayings and doings to a more tentative, open and partial interpretation of native sayings and doings (Geertz 1973). Yet realism remains a governing style for a good deal of ethnography, descriptive or interpretative. It is marked by a number of compositional conventions that include, for example, the suppression of the individual cultural member's perspective in favour of a typified or common denominator 'native's point of view' the placement of a culture within a timeless ethnographic present and a claim for descriptive or interpretive validity based on the author's 'being there' (fieldwork) experience.

Some ethnographers, though by no means all, express a degree of dissatisfaction with ethnographic realism (Marcus and Fischer 1986). Partly a response to critics located outside ethnographic circles who wonder just how personal experience serves as the basis for a scientific study of culture, some ethnographers make visible—or, more accurately, textualize—their discovery practices and procedures (Agar 1980). *Confessional ethnography* results when the fieldwork process itself becomes the focus in an ethnographic text. Its composition rests on moving the fieldworker to centre stage and displaying how the writer comes to know a given culture. While often carefully segregated from an author's realist writings, confessional ethnography often manages to convey a good deal of the same sort of cultural knowledge put forth in conventional realist works but in a more personalized fashion (e.g. Rabinow 1977).

Other genres utilized for ethnographic reporting are available as well. *Dramatic ethnographies,* for example, rest on the narration of a particular event or sequence of events of apparent significance to the cultural members studied. Such ethnographies present an unfolding story and rely more on literary techniques drawn from fiction than on plain-speaking, documentary techniques—'the style of non-style'—drawn from scientific reports (e.g. Shore 1982). *Critical ethnographies* provide another format wherein the represented culture is located within a larger historical, political, economic, social and symbolic context than is said to be recognized by cultural members, thus pushing the writer to move beyond traditional ethnographic frameworks and interests when constructing the text (e.g. Nash 1979). Even self or auto-ethnographies have emerged in which the culture of the ethnographer's own group is textualized. Such writings offer the passionate, emotional voice of a positioned and explicitly judgemental fieldworker and thus obliterates the customary distinction between the researcher and the researched (e.g. Young 1991).

A good deal of the narrative variety of ethnographic writing is a consequence of the post-1970s spread of the specialized and relatively insular disciplinary aims of anthropology and, to a lesser degree, sociology. Growing interest in the contemporary idea of culture—as something held by all identifiable groups, organizations and societies—has put ethnography in play virtually everywhere. No longer is ethnography organized simply by geographic region, society or community. Adjectival ethnographies have become common and sizeable literatures can be found in such areas as medical ethnography, organizational ethnography, conversation ethnography, school ethnography, occupational ethnography, family ethnography and many more. The results of the intellectual and territorial moves of both away and at-home ethnography include a

proliferation of styles across domains and an increase in the number of experimental or provisional forms in which ethnography is cast.

The expansion of ethnographic interests, methods and styles is a product of the third moment of ethnography—the reading of ethnographic texts by particular audiences and the kinds of responses these texts appear to generate. Of particular interest are the categories of readers that an ethnographer recognizes and courts through the topical choices, analytic techniques and composition practices displayed in a text. Three audience categories stand out. First, collegial readers are those who follow particular ethnographic domains most avidly. They are usually the most careful and critical readers of one another's work and the most familiar with the past and present of ethnography. Second, general social science readers operate outside of ethnographic circles. These are readers attracted to a particular ethnography because the presumed facts (and perhaps the arguments) conveyed in the work helps further their own research agendas. Third, there are some who read ethnography for pleasure more than for professional enlightenment. Certain ethnographic works attract a large, unspecialized audience for whom the storytelling and allegorical nature of an ethnography is salient. Such readers look for familiar formats—the traveller's tale, the adventure story, the investigative report and, perhaps most frequently, the popular ethnographic classics of the past—when appraising the writing. Ironically, the ethnographer charged with being a novelist manqué by colleagues and other social scientists is quite likely to be the ethnographer with the largest number of readers.

For each reader segment, particular ethnographic styles are more or less attractive. Collegial readers may take in their stride what those outside the field find inelegant, pinched and abstruse. The growing segmentation across collegial readers suggests that many may be puzzled as to what nominal ethnographic colleagues are up to with their increasingly focused research techniques and refined, seemingly indecipherable, prose styles. This creates something of a dilemma for ethnographers for it suggests the distance between the general reader and the ethnographic specialist as well as the distance between differing segments of ethnographic specialists themselves is growing. While ethnography itself is in little or no danger of vanishing, those who read broadly across ethnographic fields may be fewer in number than in generations past. This is a shame, for strictly speaking an unread ethnography is no ethnography at all.

ethnomethodology

The term ethnomethodology was coined by Harold Garfinkel, whose *Studies in Ethnomethodology* (1967) set the directions for a unique field of sociological investigation. As the word ethnomethodology implies, it is the study of 'people's methods'. It is partly akin to the anthropological ethnosciences (the study of folk systems of measurement, botanical classification, colour categories, astronomy and music), but its domain—everyday methods for producing social order—is more inclusive. In most cases, ethnomethodologists study commonplace activities in their own native societies. When they study exotic or specialized domains of practice they attempt to master the relevant linguistic and embodied competencies, preparatory to explicating their endogenous organization.

Ethnomethodology is defined not only by its subject matter, but also by a distinctive, and often controversial, conception of social order. From Talcott Parsons (1937), Garfinkel inherited a general sociological orientation to social action and social structure, but he radically transformed the theoretical *problem* of order into a descriptive orientation to the quotidian *production* of social order. Garfinkel's solution was not framed as a coherent theoretical answer to the foundational question of how order is created out of disorder; instead, it pointed to how the relentless, *ad hoc* production of ordinary social activities obviates any need for a formal theoretical solution. The idea was to identify and describe the diverse language games through which social order is *performed* on the street. This proposal borrowed liberally from existential phenomenology and Wittgenstein's later writings, but above all it was developed through Garfinkel's and his students' detailed investigations of everyday activities.

In addition to studying ordinary practical and communicative actions—for example, conversation, wayfinding, driving in traffic—ethnomethodologists investigate the embodied, communicative performance of social and natural scientific methods (Garfinkel *et al.* 1981). In line with the effort to describe the *accomplishment* of social order, ethnomethodologists try to detail the production of natural order without

suggesting that scientific facts necessarily become any less factual for being so described. Unlike social constructivists, they do not frame the 'construction of facts' in causal or quasi-causal terms, and generally they do not attempt sceptically to undermine the objectivity of science and mathematics (Lynch 1993). Instead, they endeavour to show what can be *meant,* under different circumstances of enquiry and for all practical purposes, by fact, artefact, discovery, objectivity and the like. The policy with regard to such topics is one of 'indifference' rather than scepticism (Garfinkel and Sacks 1970).

Ethnomethodology is not itself a social science method. Leading figures in the field have repeatedly emphasized that there is no obligatory set of methods, and no prohibition against using any research procedure whatsoever, if it is *adequate* to the particular phenomena under study. Nevertheless, ethnomethodologists tend to use particular research techniques. Especially in the associated programme of conversation analysis, practitioners typically analyse audio and videotapes of conversations, meetings, interrogations, and continuous sequences of embodied action. These data are understood less as empirical evidence about an external world than as intelligible constituents of a life-world inhabited by participants and analysts alike. As the late Harvey Sacks, the founder of conversation analysis, noted, the 'single virtue' of tape-recorded materials is that they provide detailed records of activities, which permit extended and repeated study in a community of investigators (Sacks 1984:26). Accordingly, rather than representing *facts* in an invisible, pre-theoretical domain of natural order, the data act as strong *reminders* of commonplace scenes of action, which touch off, supplement and sometimes challenge the analyst's reflections about the genealogy of social order. The point of such investigations is to *recover*—through a kind of technical *anamnesis*—the 'oriented to' sense of spontaneously produced communicative actions.

Ethnomethodology's scientific status remains doubtful and contentious. Although ethnomethodologists attempt rigorously to describe actual, singular occasions of conduct, they do not develop causal theories or explanatory models. To an extent, the results of ethnomethodological study can be likened to *manuals* of instruction that describe how the language games under study are performed. When done well, such praxiological descriptions delve into non-obvious properties of situated conduct that elude general cognitive schemes and rule-governed models. For that reason, ethnomethodology's long-term promise is not limited to its contribution to the knowledge base of the social science disciplines. It also can contribute to a variety of other academic and non-academic efforts to document the diverse tacit knowledges—the mundane, but virtually impossible to codify, competencies—that are part of innumerable organizations of practice.

ethology

Konrad Lorenz defined ethology as 'the discipline which applies to the behaviour of animals and humans all those questions asked and those methodologies used as a matter of course in all other branches of biology since Charles Darwin's time'. Ethology is concerned with causality and the functions of behaviour, and it tries to establish the influence on behaviour of genetic, physiological and ecological variables. Ethologists also ask how and why forms of behaviour develop in interaction with the environment in the ontogeny of the individual, as well as how behaviour could have developed phylogenetically. Behaviour is thus interpreted as a contribution to adaptation to a particular environment. The methods of ethology involve primarily observation of a species in their natural environment. Having collected the data, ethologists then develop an ethogram, an inventory of behaviour of a species. This step is followed by systematic experiments and interspecific comparisons.

The origins of ethology can be traced back to Darwin. His book, *On the Origin of Species* (1859), established the basis for the concept of instinct, while even more important was his theory that natural selection underlies the behaviour of an animal as well as its morphology and physiology. Whitman (1898) also claimed that an

evolutionary perspective on behaviour was necessary; independently of Whitman, Heinroth (1910) discovered the existence of 'patterns of movements' which, like morphological structures, are comparable between species. Through such comparisons, particular behaviours could be called homologous and could be traced back to a common ancestor.

Another antecedent of ethology is purposive psychology developed by McDougall in *An Outline of Psychology* (1923) and later by Tolman in *Purposive Behavior in Animals and Man* (1932). Both postulated a factor called 'instinct' and noted that the behaviour of animals follows a purpose governed by this instinct. Craig (1918) differentiated the end of a chain of behaviours (the consummately act) from its beginning (appetitive behaviour). Appetitive behaviour is a specific seeking behaviour for a stimulus situation in which the consummately act can begin.

Modern ethology dates back to 1931 with Lorenz's 'Contributions to the study of the ethology of social *corvidae*'. This article and others that followed represented a synthesis of previously isolated efforts in ethology and led to a new model of animal behaviour. Lorenz stressed that the interpretation of animal behaviour is possible only after detailed observation of the animal in its natural environment, and that it is necessary to compare behaviours of different species.

Lorenz used a hydraulic model to describe the interaction between internal and external factors, and he redefined Craig's 'consummatory' act as the 'fixed action pattern' (FAP); the preliminary 'appetitive' behaviour was the phase leading to the performance of the FAP. Appetitive behaviour causes the animal to look for a configuration of stimuli which release the FAP. These stimuli are recognized innately according to a hypothetical mechanism, the 'innate releasing mechanism'. These signals are not only objects in the environment but also signals emitted by other members of the species, in which case signals serve a social function and are called 'releasers'. Releasers are not always equally efficient: this is because the efficiency is modulated by an 'action specific energy' which is diminished by the execution of an FAP. If only a little of the action specific energy is present, then the FAP can be executed only incompletely and thus becomes an 'intention' movement. When the FAP has not been executed for a long stretch of time, the threshold for the execution decreases and the FAP can be released even by a weak or inadequate stimulus; Lorenz termed this a 'vacuum activity'.

Lorenz's model was often criticized because it was so simple. Niko Tinbergen (1942) elaborated on Lorenz's original model. He expanded the techniques of observation through simple but ingenious experiments, and he evolved more sophisticated notions of releasers and instincts. Tinbergen defined instinct as

> a hierarchical organized nervous mechanism which reacts to priming, releasing and directing stimuli of either endogenous or exogenous character. The reaction consists of a co-ordinated series of movements that contribute to the preservation of the individual and species.

Tinbergen worked mainly on the reproductive behaviour of the stickleback and through his findings expanded our understanding of the hierarchical organization of instincts. His experiments were mostly concerned with motivational conflicts, redirected activities,

ambivalent behaviour and displacement.

Following Lorenz's and Tinbergen's seminal work, ethology spread rapidly all over Europe and (at a slower rate) to the USA. Progress was halted during the Second World War and commenced again in the 1950s with the first international publication of Tinbergen's *The Study of Instinct* (the first ecology textbook) in 1951, and Lorenz's *King Solomon's Ring,* a popularized account of ethology, in 1952.

With the growth of ethology came a major conflict between two opposing views of behaviour. First, American experimental psychology adopted a behaviourist orientation that stressed the influence of environment and learning factors; they carried out laboratory experiments using rats, cats, dogs and apes as models for humans. Second, ethology, with its systematic observation of species in their natural setting, tried to discover evolutionary and adaptive mechanisms underlying animal behaviour—the genetic basis for behaviour. Unlike experimental psychologists, ethologists studied many and diverse species, thus strengthening their case for innateness and instinct. The neglect of learning by ethologists provoked a strong reaction against the discipline from members of the opposing camp, notably by Lehrman (1953), who based his criticisms on the work of Kuo (1932).

The innate versus acquired dichotomy resulting from the debate now seems somewhat sterile and false: innate and learned are no longer regarded as exclusive categories. Contemporary ethologists would agree that behaviour develops ontogenetically through the interaction between genetic information and environment. This does not imply that an apparently innate characteristic is really learned, or that every phylogenetically pre-programmed behaviour must be adaptively modifiable through learning. But everything learned must have as its foundation a phylogenetically provided programme if appropriate and adaptive behaviour patterns are to be produced. It seems logical to postulate that certain behaviour elements—those which conduct learning processes—should never be modifiable through learning. Learned behaviour does contain genetic information, to the extent that the basis of learning is a physiological apparatus which evolved under the pressure of selection. Lorenz termed this mechanism the 'innate school-marm'. Thus the question is not whether behaviour patterns are innate or acquired but rather how behaviour can be modified, or what can be learned, and when.

From the beginning, ethology was also interested in aspects of social behaviour such as territorial behaviour, group structure, and communication. A milestone in the ethological study of communication was the development of the concept of 'ritualization' (Huxley 1966), referring to the modification of a behaviour pattern by natural selection in order to serve a communicative function. Such expressive movements mostly occur in courtship and in displays of aggression or submission. Their social function is largely to channel aggression—thus ritalized fighting or submissive behaviour hinders escalation of a fight. Bonding is another function of ritualized behaviour.

Ethologists also investigated ranking as an aspect of social behaviour. Schielderup-Ebbe (1935) found that among a flock of hens a few enjoyed privileges during feeding and had first access to the feeding site and pecked at other, lower-ranking, hens. This led on to the study of dominance, defined as having priority access to scarce resources, and measured by the number of conflicts won. This concept is now generally limited to description of relationships, while other forms of behaviour are referred to in the

construction of social hierarchies where high-ranking individuals are the focus of attention of other group members.

Other areas of interest to ethologists are the relationship between social organization and ecology (DeVore 1965); play behaviour; imprinting, or how individuals become attached to other members of the group, first observed by Lorenz in birds and studied by Hess (1973) and others. Ethologists have also considered the link between behaviour and the nervous system. Holst and St Paul (1963) elicited different behavioural reactions in hens through electrical stimulation of the brain, and Delgado (1967) was able to control aggressive behaviour using similar techniques. Neurophysiological research led to the discovery of neurons in the brain that are responsible for the control of different aspects of behaviour (Ewert 1976).

One development in ethology is sociobiology. Sociobiologists propose a global theory of behaviour which derives from the 'selfish interest' of the gene to reproduce itself; this selfishness leads to the concept of kin-selection, for related individuals share a determinable number of genes. Sociobiology's primary tools are intriguing mathematical models that consider phylogcnetic adaptation and ecological pressures. When, in certain situations, different possible behaviours exist, pressures result in the development of 'evolutionary stabile strategies' (ESS) of behaviour. Sociobiologists try to include the social sciences in a modern synthesis of evolutionary theory, arguing that all forms of social organization—in animals ranging from termites to primates, including humans—can be described using the same parameters and the same quantitative theory. They are criticized for their overemphasis on genetic determinism and for their analytical models which are strongly reminiscent of the Social Darwinism of the early twentieth century. Nevertheless they can provide new insights into the structure and organization of individuals and their behaviour, and their importance is acknowledged in the study of insects, fish and birds. But the general applicability of sociobiological laws to primates and humans has yet to be proved.

The originality of the ethological approach in the study of human behaviour was in its methods of systematic observation and qualitative description, its considerations of phylogenetic roots, and the functions of behaviour deduced from a comparative approach. Human ethology in turn influenced areas of anthropology, psychology and sociology. However, the construction of an appropriate theoretical framework still remains a problem for the human ethologist.

Development of speech is a distinguishing primary characteristic of human behaviour. This made it possible to transmit information between generations by non-genetic means. Cultural evolution then assumed a major role in the adaptation of the species. It is possible that cultural evolution follows rules comparable to those which govern phylogenetic evolution, and also leads to the modification in behaviour. Moreover, humans are capable of altering their environment, thus changing selective pressures. These possibilities make it more difficult to determine the genetic adaptive value of a behaviour, and blur the distinction between phylogenetic and cultural traits. Finally, human ethologists have tended to neglect the adaptive modification of behaviour, that is, learning processes.

Several popular books on human ethology—Ardrey's *The Territorial Imperative* (1966), Lorenz's *On Aggression* (1963), Morris's *The Naked Ape* (1967) and Wilson's

On Human Nature (1978)—brought the subject to the attention of a wider public. These authors tried to present a biological explanation for human behaviour, but they often worked with naïve analogies and simplistic comparisons. At the same time, however, an authentic human ethology was being developed. Research focused on human-ethological interpretations of child development (child ethology), as in the work of Blurton-Jones (1972) and McGrew (1972); others described children's relationships and resulting group structures. Intercultural comparisons were made in the work of Eibl-Eibesfeldt on non-verbal behaviour (1972), who also observed the expressive behaviour of children born deaf and blind (1973). These studies have shown the complexities and the multidimensional nature of ontogeny, as well as confirmed the existence of invariant transcultural traits in human behaviour, such as expressive behaviour and its ritualization.

Human ethology has moved away from its descriptive beginnings and no longer restricts itself to investigating phylogenetic adaptations in behaviour: cultural patterns are also studied in relation to adaptation, and already a number of universal social interaction strategies have been observed through cross-cultural comparison. Their apparent variation can be attributed to the fact that phylogenetic and cultural patterns can be substituted as functional equivalents for one another, or they can be verbalized. Nevertheless, the underlying structural rules remain the same. This opens the way for the study of a grammar of human social behaviour encompassing verbal and non-verbal strategies. Such an approach could provide a theoretical framework and together with the empirical research in progress could give human ethology the refinement of animal ethology.

The results of human ethological studies could have an important impact on social questions, and the dangers arising from the neglect of human nature should be clear. While the modifiability of human behaviour, especially through educational programmes, is limited, this knowledge should not be used to justify a freeze on social changes, as extreme conservatives have already suggested. Indeed, this view was possible only because of the oversimplification of the field by popular writers. Rather, the universals identified by human ethology, especially in communication and in mechanisms of group cohesion and seclusion, could be the basis for shared concern and a common understanding and could provide a means to overcome ethnocentric political strategies.

European economic and monetary union

The countries of the European Union are formally committed to full economic and monetary union provided the conditions set out in the Maastricht Treaty 1992 are achieved. A monetary union between nation-states is distinct from an economic union. An economic union consists of a single market for goods, services, capital and labour with no imposed barriers or distortions to impede their free flow within the area. A monetary union also requires irrevocably fixed exchange rates between the component

parts, possibly a common currency, and a centralized union-wide monetary policy.

To date (with the exception of Belgium and Luxembourg) the only viable and sustained monetary unions have been based on nation states. Attempts have been made to link countries in monetary unions (such as in Africa) but none has been conspicuously successful. The basic characteristics required for an effective full monetary union are strict:

1　There is no exchange control between the component parts, which means that capital is free to flow without impediment within the union.
2　There is no possibility of any internal exchange rate change as there is a common currency or an internal regime of complete and irrevocably fixed exchange rates.
3　There is a single union-wide central bank which is responsible for the conduct of monetary policy.
4　Monetary policy is conducted at the level of the union and not the component regions.
5　A common payments system exists throughout the union.
6　There is a union-wide capital market and banking system both subject to a common regulatory regime.
7　Although subsectors (e.g. states or countries) may have their own budgets, there is also a union-wide budget of the central government. Through this central budget there are in-built regional transfers such as when a depressed region automatically pays less tax and receives more government payments. There may also be explicit regional policy mechanisms built into fiscal policy.

Thus the essential features of a monetary union are centralized policy decision making with reference to the economic and financial circumstances of the union as a whole. Regions become subservient to the union despite the fact that their economic circumstances may be different. The major policy implication is that members of a European Monetary Union (EMU) would surrender sovereignty to pursue independent national policies in two main areas: with respect to setting the level of national currencies exchange rates, and over the conduct of monetary policy (the setting of interest rates and the growth of the money supply). If a common currency is created (though this is not a necessary condition for a monetary union) the possibility of internal exchange rate adjustments is by definition removed. It is for these reasons that the establishment of a EMU would also require the creation of a European Central Bank to determine the union's monetary policy.

The argument for European Monetary Union is that, as the degree of economic and financial integration between member states increases (and this will develop further with the complete abolition of exchange control and the completion of the internal market during the 1990s), so the relationship between member countries approaches that which exists between different regions or counties within countries. Proponents argue that to make the internal market effective (as it is in the USA where there are semi-independent states with different laws and budgets) it needs to be set within a monetary union with a single currency; it is a means of making the internal market effective which is a major reason why the issue of EMU has resurfaced in the 1990s following the commitment to complete the internal market programme.

Several benefits could derive from this, not the least being that there are no internal balance of payments financing problems or speculative capital flows which may, from time to time, induce financial crises. The major advantage is that, as uncertainty associated with exchange rate risks is eliminated, and there are no transactions costs involved in having trade conducted in several currencies, the volume of interregional trade is higher. At the same time capital and savings are allocated within the union to where the rate of return is highest. A further advantage is that it removes the potential conflicts and uncertainties that can arise through the conduct of divergent and non-cooperative national economic and monetary policies.

However, it also means that policy of any region is determined nationally and in the interests of the union as a whole rather than that of the region, and that monetary policy is not differentiated to reflect the particular economic circumstances of different regions. It also means that high unemployment in a region associated with uncompetitiveness cannot be offset by an exchange rate adjustment. It removes the policy autonomy and sovereignty of the component parts to choose their own economic policy and objectives (most especially with respect to any trade-off that might exist between unemployment and inflation) and to respond to asymmetric shocks. It is also argued that the conditions required to make Europe an optimal currency area (high mobility of labour, etc.) do not exist. In addition, and compared to the operation of the European Monetary System (EMS), the issue arises as to whether the credibility of a newly created European Central Bank would be as great as that of the Bundesbank within the EMS.

In the final analysis, the objection to creating a monetary union is the implied loss of policy sovereignty. But the question arises as to how much effective sovereignty governments in practice have in countries which are highly integrated with other countries. The issue is therefore about how powerful national independent policy mechanisms are in an increasingly integrated Europe. The fact that a country has its own currency, conducts its own monetary policy, and sets its own budget, does not guarantee that it has a truly independent policy; it may have unimpaired *nominal* sovereignty but little *effective* sovereignty.

A major milestone en route to a European Monetary Union was set in the Maastricht Treaty of 1992. An irrevocable process was agreed which implies a binding commitment to creating a monetary union providing stated conditions are met. As the treaty stands, a monetary union *could* be created in 1997 if the majority of member states agree, and *will* be created in 1999 but only for those members which satisfy strict convergence criteria with respect to inflation, interest rates, size of budget deficits, etc. A distinct possibility is that only a limited number (possibly as few as two or three) of members will form a monetary union which gives rise to the possibility of a 'two-speed Europe'.

event-history analysis

Event-history analysis bases itself principally on the hypothesis that human behaviour is generated by a stochastic process. Its more general aim therefore is to estimate the probability distribution of the life courses followed by a given population over time. An individual event-history appears as a result of a complex process, which develops during the life course, yet is situated within given historical, economic, political and social conditions. This process is affected by social structures but in turn may alter them in a dualistic way.

During the 1970s and 1980s, the amount of reliable life-history data produced by surveys (fertility, family, occupation and migration surveys) increased considerably. At the same time, probability theories and statistical methodologies developed, resulting in techniques for handling such data. One such technique, event-history analysis, is now used in a growing number of disciplines, notably demography (Courgeau and Lelièvre 1992), econometrics (Lancaster 1990) and sociology (Tuma and Hannan 1984).

Traditional models focus on a single event or on a sequence of similar events, such as successive births for a woman. Their occurrence is studied from a dynamic temporal perspective, modelling via the events' probability functions and accounting for incomplete information by different censoring mechanisms, of which right-censoring at the end of an observation is the most widely known and studied example. However, as individuals experience events in different spheres of life (occupational, educational, migration, family and other histories), the study of such parallel and interacting histories requires much more complex multistate models, enabling us to examine interaction between two or more processes and to extend the analysis to more intricate situations. These models lead to new concepts of dependency in social sciences, for example, local dependence. We can thus formalize the notion that one given process may influence the local development of another without reciprocity. Simultaneously it is necessary to deal with heterogeneity in populations and to investigate the impact of certain individual characteristics, possibly time-dependent, on the occurrence of events. Semiparametric

regression models, first introduced by Cox (1972), are extensively used to analyse the observed heterogeneity of populations and its effect on the timing of given events. This heterogeneity comes from family origins, educational characteristics or, more generally, from the past life history of the individual. Unlike standard regression models, these models have no error term and omission of important covariates raises problems of unobserved heterogeneity. Such problems have led to much discussion in the field since the same observed outcomes may be generated by different models.

Event-history analysis had led to numerous innovations in various fields of the social sciences and is bringing new challenges to research into more complex social units such as households or families.

evolution

see **evolutionary economics; evolutionism and progress; human evolution**

evolutionary economics

The central concern of evolutionary economic analysis is to explain why and how the economic world changes, its subject matter is dynamics, and its purpose is to make sense of the immense variety of behaviour which comprises the rich tapestry of historical change. Evolution does not mean change *simpliciter* but change in the relative

frequencies of specified entities within a population and subject to the operation of specific mechanisms. This is a theme to which the historical record speaks with great eloquence and persistence (Landes 1968; Mokyr 1991). The ever-changing structure of the economic fabric, as witnessed in the growth and decline of firms, cities, regions and nations, reflects evolution operating at different levels and with different speeds, as does the emergence over time of completely new areas of economic activity. The displacement of gas by electricity, the spread of robotic tools in the workplace, the displacement of corner shops by super-markets, the growth of part-time relative to full-time employment and the shifting balance of employment between agriculture, manufacturing and services in their different ways draw upon the same mechanism, whose mainspring is variety in behaviour. That is the fundamental fact which makes any social science the investigation of interaction between individuals and organizations.

As with modern evolutionary theory, the process is applicable at many different levels of economic activity depending on what are taken to be the appropriate units of selection. But whatever the level the issues are the same, the specification of variety in behaviour, the identification of the selection mechanisms which resolve that variety into economic change, and the analysis of feedback and other mechanisms which shape and regenerate variety over time. Inherently this involves a population perspective in which any idea of representative behaviour is utterly redundant except as a statistic artefact. Before illustrating these remarks it is useful to remember Lewontin's (1982) famous requirements for an evolutionary theory, namely entities possessing different characteristics or behavioural traits; a mechanism which assigns differential fitness to entities as they interact with other rival entities in a selection environment; and heritability, the transmission through time of the behavioural traits. We should dispose of this last point first because, *contra* naïve views on evolution, no reference to any genetic mechanism is involved or implied. What is important is stability and persistence of behaviour over time, that tomorrow's behavioural traits are correlated with those of today. Thus, inertia is an important conserving element in the picture and it will be obvious that evolution cannot occur in a world where individuals or organizations behave randomly. As to the origins of variety in economic behaviour, there is a natural emphasis on matters of technology, organization and management, that is, upon the knowledge of how to act in order to acquire beneficial behavioural traits. The entrepreneur is fully at home in an evolutionary world, and perhaps no other, for the very definition of entrepreneurship entails variety in behaviour of individuals or organized groups. Does evolution entail rationality? Apparently not. In a world in which knowledge is costly to acquire, and computational competence is bounded there is little ground for invoking omniscient optimization as a behaviour yardstick. There is nothing amiss with the idea that individuals seek the best outcome of any set of options, but such calculations as are involved are necessary local solutions not global solutions. Here lies a powerful source of differential behaviour; individuals know different things, they live in the same world but perceive (imagine?) different worlds. Hence it is not surprising that evolutionary analysis finds the idea of bounded rationality to be of central importance; that it specifies behaviour in terms of stable rules which themselves evolve over time; and, that it insists upon the benefits to be gained from the study of the internal working of organizations (Nelson and Winter 1982). Since the foundation of many of these issues is the acquisition

of knowledge it is evident that there are close affinities with the emerging field of evolutionary epistemology (Hull 1988; Plotkin 1994). Nor is intentionality of economic behaviour a problem; quite the contrary, it helps us to understand how economic variation is guided and channelled while underpinning the central point of individuals and organizations behaving differently (Hodgson 1993). The simple point to grasp is that the sources of economic variety are far richer than the sources of biological variety.

A typical if basic picture of economic microevolution is as follows. It concerns a population of rival firms each producing one or more products, each product with its own methods of production as dictated by the firm's technology, organization and management rules. The firm is a vehicle for many co-ordinating activities which ultimately result in the production of saleable output, co-ordinating activities which evolutionists call replicators for they result in the firm generating copy after copy of its own behaviour The firm interacts in markets with other firms to sell its products and purchase production inputs and the result of these market interactions determines the economic quality of its products, the prices at which it can sell them and the economic costs of their production. Users are continually comparing one product with another, and switching their allegiance to what they perceive to be better quality and price combinations, while firms deploy their profits in part to accumulate productive and marketing capabilities. In short, the underlying differences in behavioural rules lead to different prices, costs and levels of profitability which provide the basis for dynamic change: the general rule being that more profitable firms expand at the expense of less profitable rivals. Or to put it more accurately, there is market selection *for* products and their methods of production and consequent selection *of* the rival firms (Sober 1984). It is these differential rates of increase which correspond to the notion of economic fitness. If such a process is imagined to run in unchanged circumstances, the frequency distribution of output will concentrate on the firms with lower costs and superior products and it will gradually eliminate other firms according to the prevailing rules of bankruptcy.

Evolution and market concentration go hand in hand, which means that competition destroys the very variety on which it depends. Thus, if economic evolution is not to cease, mechanisms must be in play to regenerate that variety. Innovation is thus a central component of the macroevolutionary story, and economists have learned to think of this in terms of guided variation within existing technological activities, together with the less frequent emergence of conceptually new productive opportunities. What is important for present purposes is the dependence of innovative creativity on feedback from the selection process. Internally generated profits are a principal source of funds for such risky activity, while experience gained in pursing particular activities is a major stimulus to push the pattern of improvement in particular directions. Seeing innovation as random mutation, as in genetics, is not necessarily misplaced but this is certainly not the whole story. In this regard, innovation can gain a self-reinforcing momentum of its own as the process of competition reveals fresh possibilities, and, in the presence of such positive feedback, small historical events can have lasting consequences. In making sense of variety, evolution also makes sense of history.

Implicit in the above is a dual perspective on economic evolution. Much of it is concerned with the traditional role of markets as co-ordinating mechanisms. It is in market interactions that the profitability of different behaviours is determined and thus

the resources to invest and innovate in the corresponding activities to which those behaviours relate. This involves competition within and between industries; it is an externalist view of evolution taking the unit of selection in relation to its environment. Equally important is an internalist perspective concerning the process of conjecture formation and selection which takes place within organizations and defines how the relevant bundle of behavioural rules evolves over time. Internal and external processes interact at different speeds and at different levels in complex intriguing ways. What happens within the community of science, for example, as it selects from novel hypotheses, provides material which firms can adopt and adapt as they seek sustainable competitive advantages. Equally, how governments perceive their regulatory role has clear implications for the dual perspective in economic evolution.

Many scholars have found an evolutionary perspective in economics to be appealing. Cut free from any dependence on biology and with the tools of modern mathematics and computation at its disposal, there is a rich agenda to be explored, an agenda which ultimately reduces to a question of the processes which generate and which limit the generation and spread of economic variety. In this it tackles one of the oldest of philosophical questions: how does order and structure emerge from diverse behaviours? If not universal Darwinism at least a broader picture of evolution and its place in shaping history.

evolutionism and progress

Evolutionism is the label now commonly used for a current of thought which was strongly represented in the anthropology and sociology of the nineteenth century. Although it fed on biological analogies, it must be clearly distinguished from Darwinian thinking. Its inspiration came rather from the older tradition of Lamarckian evolutionary theory, which provided the main rival to Darwinian theory until well into the twentieth century. Key elements in this tradition were the beliefs that organisms were intrinsically bound to improve themselves, that changes were progressive and often radical and sudden, and that acquired characters could be transmitted genetically. Typically, the stages of ontogeny, or the individual life history, were taken to exemplify the stages of phylogeny, the development of a species.

Herbert Spencer, one of the most consistent exponents of the organic analogy in the social sciences, was perhaps the leading evolutionist in sociology, but these general ideas were taken for granted by authors as diverse as Marx, Freud and Durkheim, and they survived in some modern theories in anthropology (e.g. Childe 1951), in the psychological theory of Piaget, in 'Whig' history, and so on. The evolutionist assumptions were, however, directly in contradiction to the Darwinian theory of evolution by variation and natural selection, which did not assume the existence of any progressive line of change. On the contrary, Darwin stated emphatically that 'I believe in no fixed law of development'.

Evolutionist theory in the social sciences should perhaps be regarded as part of a broader tradition of theories of progress, which represents the most deeply entrenched way of conceptualizing social history in the west. It has a particular appeal to progressive radicals and utopians, while the mirror-image theory, that the trend of history is towards social and cultural decadence, is, on the other hand, associated rather with right-wing political theories and with religious revivalism. Whether the unit of perfectibility was assumed to be humanity or a particular civilization or race, the theory was so abstract and value-laden as almost to defy empirical reference. Nisbett (1980), nevertheless, argues that the faith in progress has been eroded by a widespread scepticism about the unique superiority of contemporary western civilization.

exchange

Exchange is interesting for five reasons: it is the means by which useful things pass from one person to another; it is one of the ways in which people create and maintain social organization; it is always regulated by religion, law, convention and etiquette; it is always meaningful because it carries a symbolic load, and is often a metaphor for other kinds of activities; finally, in many societies people speculate about its origins, about the motives for and the morality of it, about its consequences and what its essence might be. It is rare to find a scholar who gives equal attention to each of these aspects of the topic.

Exchange is universal: we know of no peoples who admire individuals who do not exchange, or who expect a category of people to refrain from it. Although people in industrial and market-organized countries sometimes imagine the attractions of self-sufficiency, and try to achieve it, it would be a new creation if they succeeded. It is true that in every social group some individuals are more engaged in exchange than others, but it is probably a mistake to imagine that some peoples exchange more than other peoples.

People distinguish among kinds of exchange: in English-speaking countries they talk of altruism, barter, charity, commerce, gifts, taxation and theft, among others. These distinctions are based on expectations of return: whether there should be one, whether it should be immediate or after a period of time, whether it should be equivalent or greater or less. This too is universal, although the kinds available to different peoples are variable. People also categorize kinds of goods as being more suited to one kind of exchange than another: some peoples have goods which are exchanged only as gifts (greetings cards in many countries, *vaygua* in the Trobriands, and so on). They also prohibit the exchange of certain kinds of goods: in Christian thought, for instance, the purchase of spiritual office is distinguished as a named sin (Simony). People also often categorize kinds of exchange as particularly suited to kinds of relationships: friends and family should give gifts in Britain, judges and litigants should not. Where a kind of exchange is reserved to a kind of relationship, people may try to establish the relation by making the exchange. Marcel Mauss (1954 [1925]) noted that a refusal to accept a gift, or to return one, caused great offence, and could be equivalent to a declaration of war.

Social scientists, and in particular anthropologists, have tried to identify systems of

exchange. They have done this in various ways. The pioneer was Mauss, who explored gift-giving as a type of exchange based on three obligations: to *give,* to *receive* and to *return;* these are still taken to be the key principles. Mauss's archetypal gift was one so heavily laden with symbolic meaning and consequence that it involved the 'total social personality' of the exchangers (who might be either individuals or groups of people), and success or failure in making exchanges affected their social standing. The potlatch (in which groups try to overwhelm competitors with gifts) was thus interested, but not directly profit-motivated. This is the first attempt to identify a non-market system of exchange by the principles on which the exchanges are made. Malinowski's (1922) exploration of *kula* exchanges between a number of Melanesian islands showed that ceremonial goods circulated by reciprocal gift-giving in the *kula* ring affording the opportunity for trade and establishing peace between neighbouring islands as well as maintaining hierarchy on particular islands: some people were more successful in the *kula* than others. Studies suggest that the ring was less systematic than Malinowski thought (Leach and Leach 1983). In later elaborations, deriving also in part from the work of Karl Polanyi (1944), the principle of reciprocity has been taken to identify a kind of economy: some economies are based principally on reciprocity, others on markets, others on the redistributive activities of chiefs and governments. Sahlins (1972) is noted for his unique attempt to show that different principles were consequential, and were not just *amusettes folkloriques:* economies performed differently as a result. This was especially important because economists and others attempted to show that forms of rational profit-seeking underlay all exchange, and that the differences shown in the ethnographic record were either imperfections (this a term of art of economists) or a manifestation of false consciousness.

The attempt by Lévi-Strauss (1969) and his followers to link formal structures of kinship and marriage to systems of exchange of women has proved most fruitful in kinship studies.

The principle of rational exchange was the basis of exchange theory, derived from the work of von Mises, and elaborated in sociology by Homans (1961) and Blau (1964) and in anthropology by Barth (1966) and Bailey (1969). The attractiveness of such theories derived in part from the shock of describing all social activity as profit-motivated. It also probably derived from the apparent ease with which market principles diffused so quickly in the 1950s and 1960s. This process was widely recorded, perhaps most successfully in the analysis by Bohannan and Bohannan (1968) of the decline of Tiv categories of exchange, when confronted with national markets: the apparent success of 'the modern economy' seemed to justify the adoption of a modern economics to explain everything. Anthropologists and some economists are now less sure. It is possible that some valuable lines for future research have already been established: these include Appadurai's (1986) investigations of the ways that things change meaning as they change hands, and Strathern's (1988) work on symbolism; Gregory's (1982) exploration of the distinction between *gift* and *commodity,* and work by economists and others on the mixed motives with which people engage in exchange, even in so-called market economies.

exchange rate

The exchange rate is a price: the price of one currency in terms of another. A distinction is made between the *nominal, effective* and *real* exchange rate. The *nominal* rate is a bilateral price expressed and quoted either as the number of units of the domestic currency per unit of another, or vice versa.

The *effective* exchange rate is an index of a currency's value in terms of a weighted basket of other currencies. Movements in this index show how a currency has moved, not against a single currency, but against the group of currencies in the basket. Movement in the effective rate is a weighted average of divergent changes in nominal rates.

The exchange rate (nominal or effective) determines the competitive position of domestic output in international markets. At constant domestic prices it gives the foreign currency price of a country's exports and hence influences foreign demand for domestically produced goods. Similarly, at constant foreign currency prices, the exchange rate determines the domestic currency price of imports and hence influences the demand for imports. Movements in the exchange rate can, therefore, have a powerful influence on the competitive position of goods and services produced in different countries and thereby influence the pattern of international trade flows.

The *real* exchange rate calculation adjusts movements in either a nominal or effective exchange rate for relative changes in the domestic price of goods in the country of production. Thus, if a currency depreciates by 10 per cent while its rate of inflation is 4 per cent more than its competitors, the real exchange rate has declined by 6 per cent.

The theory and empirical evidence about the determination of the exchange rate are far from settled. Flow theories tend to concentrate on the current account of the balance of payments and therefore on the factors (such as relative price and income movements between countries) influencing trade flows. The exchange rate is viewed as an equilibrating mechanism for the current account. Portfolio theories, or the assetmarket approach (of which the monetary theory of the exchange rate is one of many variants), concentrate on the required conditions for equilibrium in wealth-holders' portfolios. In these models, movements in the exchange rate reflect an excess supply or demand for financial assets as between countries. A depreciation is viewed as a sympton of an excess supply of domestic financial assets. Stability in exchange rates requires, in these models, consistent monetary policies as between countries.

Governments have an interest in the level and stability of exchange rates. As movements influence the domestic price of imports, they have an effect on the domestic price level and, dependent upon how wage bargainers respond, the rate of inflation also. Through the same mechanism the exchange rate affects the level of real income and wages at each level of output. To the extent that the international competitive position of domestic goods is affected, movements in the exchange rate have implications for the level of output and employment. Thus governments might resist an appreciation because of its adverse employment effects, but also a depreciation because of the prices effect.

experimental design

The function of experimental design

Experiments involve introducing a planned intervention (usually referred to as a treatment) into a situation, with the intent of inferring the association of treatment with a resulting change or outcome. Good experimental design facilitates this inferential process in three ways.

First, it translates all aspects of one's hypothesis—the statement of expected relation of treatment to outcome—into operational terms: subjects, behaviours, situation, equipment,

procedures, and so on. These permit the hypotheses to be tested empirically.

Second, it rules out those alternative explanations which provide the most serious challenge to the treatment as the explanation for change. For example, because of faulty design, an experimental group was tested, exposed to a treatment, and post-tested. Improvement on the second testing could be attributed to familiarity with the test, thus providing an alternative explanation.

Third, it facilitates relating the change to other variables, thus permitting better understanding of the relationship. For example, with proper design, one could tell whether a treatment was more successful with men than women and with older than younger subjects, or its relation to any other variable included in the design.

The logic of experimental design

The first step in experimental design is to translate expectations expressed in one's hypotheses into operational terms. For example, given the hypothesis 'outlining in advance improves writing' one must specify what constitutes sufficient prior organization to be considered outlining and in what aspects of writing one expects gains. The accuracy of this translation is critical. If what passes for outlining in the study does not accurately reflect what is typically intended by the term, or the writing measure is inaccurate or insensitive, misleading conclusions could result.

Following operationalization, one must create a situation in which the treatment can occur as intended and changes can be sensed. Sometimes one compares the pre- with the post-intervention condition of the experimental subjects. In other instances, experimental subjects may be compared with an untreated comparable group, a control group. In still other instances, post-treatment condition is compared with estimates of the untreated state, for instance, test norms or regression estimates made from previous data on comparable groups.

By appropriate choice of design, one rules out whatever alternative explanations may be important rivals to that intended. For example, if a control group is used, the groups may not have been equivalent to begin with, or dropouts may make them non-equivalent at the end. Alternative explanations common to many studies have been identified (see below) but some may be unique to a study. For example, if subjects are allowed to complete a test at home, their score may reflect more their ability to seek help than their own achievement.

Assuming that the data support one's expectations, these steps in the logic follow: since the results were as predicted; and since there is no reasonable explanation for the phenomenon other than the treatment (others having been ruled out by one's design); then the hypotheses escaped disconfirmation. While one cannot test the hypothesis in every situation, one infers from this that similar predictions would prove accurate in like instances. With each such confirmation, confidence in the hypothesis increases, but a single disconfirmation, without a reasonable explanation, is sufficient to disprove it.

Experimental control

It is difficult to provide sufficient experimental control to protect against every possible alternative explanation. Further, one typically buys protection at a price. For example, a laboratory gives more complete control, but laboratory circumstances are rarely like those to which one hopes to generalize. Yet, natural circumstances may provide too little control. Zimbardo *et al.* (1981) supply an interesting example of this dilemma and its solution. They hypothesized that the paranoid behaviour frequent in elderly people was due to the gradual unnoticed loss of hearing common in old age. An expensive longitudinal design following subjects over time would have been inconclusive because of the subjects' varying social experiences. In addition, it would involve the unethical behaviour of withholding hearing loss information to see if the paranoid behaviour developed.

The researchers devised a creative experimental design. Post-hypnotic suggestion produced a temporary unnoticed hearing loss in college student volunteers with resulting display of paranoid behaviour. To eliminate rival alternative explanations, two control groups of similar subjects were established: one received the post-hypnotic suggestion of a hearing loss of which they would be *aware* and another received a neutral post-hypnotic suggestion in order to show that the hypnotic process itself did not induce paranoid behaviour. The paranoia was shown to follow only unnoticed induced hearing loss, and all subjects were exposed to controlled similar social experiences following hypnosis. Altogether, this is a clever use of experimental design for an otherwise difficult problem.

But using a laboratory-like setting may not be without costs to the validity of one's inferences. Impressed by the scientific laboratory, subjects may have tried to please the researcher; in addition, the researchers, knowing which was the experimental group, may have unintentionally cued subjects to appropriate behaviour (Rosenthal 1976). The verisimilitude of the hypnotically induced hearing loss to that which occurs in older people may be questioned, as may the use of college students.

Nearly every design choice involves trade-offs in the use of resources which might have been used to control something else. Part of the art of design is finding a suitable middle ground, one realistic enough to allow generalization of the results as broadly as one wishes but permitting sufficient control to make valid inferences.

The criteria of good design

A good design reduces one's uncertainty that the variables are indeed linked in a relationship and the linkage has generality. Showing that they are linked requires internal validity (LP) where (LP) stands for 'linking power'—the power of the study to link the treatment with the outcome (Krathwohl 1993). A study has strong internal validity (LP) when the explanation advanced for the relationship is credible, when the translation of variables into operational terms is faithful to that originally intended, where a relationship is demonstrated in the data, where rival explanations for the relationship are eliminated,

and when the results are consistent with previous studies (Krathwohl 1993).

Similarly, demonstrating generality requires external validity (GP) where GP stands for 'generalizing power'—the power of the results to be generalized beyond the instance in which they were demonstrated (Krathwohl 1993). External validity (GP) assures the applicability of the results to other persons, places and times, and that the generalizability was not restricted by the conditions of the study. A study has strong external validity (GP) when the generality implied by the hypothesis, or inferred from it, is consistent with the choices made in operationalization of the study; that results were appropriately found throughout the instances of the study as expected; that there were no conditions of the study that limited generalization; and that the same results would have been expected were the study operationalized and designed in alternative ways.

Good designs accomplish the above with the best use of all available resources, time and energy. They fit the design to the problem rather than changing the problem definition to fit design requirements. They appropriately balance internal and external validity: strengthening internal validity is generally done at the expense of external validity. They accurately anticipate those alternative explanations to be eliminated that are most plausible to one's audience. Finally, ethical standards, resource limitations and institutional and social constraints are observed: altogether, a complex but manageable set of criteria (Krathwohl 1993).

Common alternative explanations

Certain common conditions provide as plausible explanations of an outcome as the treatment. Called 'threats to validity', they were described by Campbell and Stanley (1963) and Cook and Campbell (1979):

1 *Testing:* pre-treatment testing may affect post-treatment testing, especially if the same test is used. A control group provides protection since its post-test would be equally affected.
2 *Selection:* those selected for the experimental group differ from their controls, for example, when the experimental group consists of all volunteers and the control group comprises the remainder. One remedy is to use volunteers randomly assigned to experimental and control groups.
3 *Testing by treatment interaction:* subjects sensitized to aspects of a treatment by pre-testing react differently to post-testing. A post-test only design provides protection.

Common designs

Single group designs

These are often called time-series designs; relations are inferred from the pattern of treatment and response over time:

1 For static situations: pre-measure, treat, post-measure.
2 For situations with a regular pattern: observe it, treat, and determine if the pattern was disturbed.
3 With either an irregular pattern or for an especially conclusive demonstration, relate the pattern of change to that of treatment, intentionally varying the latter's timing, length, strength, and such other factors as affect outcome.

Also referred to as AB, ABA, or ABABA designs (A is the untreated condition, B the treated), ABABA and more complex designs are useful only where the change under the B condition is impermanent. (For information on such designs see Kratochwill and Levin 1992.)

Multiple group designs

These designs may involve both multiple experimental and control groups (Zimbardo used two control groups). Groups are alike as far as possible except for the conditions to which change is to be attributed. But only one condition can be different between groups being compared. Assuring group equivalency is usually achieved by randomly assigning subjects. *On the average* this will equate them for everything, from length of eyelashes to motivation.

The simplest, yet very effective, design involves post-testing only. Let R indicate random assignment of subjects to groups, O a test or observation, and X treatment. Then it is diagrammed as:

R   X   O
R   O

To assure that the groups were equivalent at the outset, a pre-test may be added:

R   O   X   O
R   O   O

But this introduces both testing and testing by treatment interaction as possible alternative explanations. For better control, the Solomon four group design combines the previous two:

R   X   O
R   O
R   O   X   O
R   O   O

Designs in which groups are not created by random assignment of subjects (same designs as above without the R) are designated quasi-experimental designs. Their strengths and weaknesses are explored in Campbell and Stanley (1963) and in Cook and Campbell (1979).

Blocking equates treatment groups. It does so by dividing the sample into blocks or strata on one or more characteristics (for example, intelligence and rank in birth order) where non-equivalence might affect the outcome. Individuals are randomly assigned to treatments within blocks. The matched pairs design is an extreme form of blocking.

Factorial designs

Factorial designs permit analysis of the simultaneous effects of two or more treatments or related variables by providing a group for each possible combination. For instance, to study the effect on speed of prose memorization of bold, italics and underlining of important parts, and of printing them in black or in red would require six groups—a 2×3 factorial design:

	Bold	Italics	Underlining
Black type			
Red type			

From this design one could learn which emphasis, treatment or colour was best alone, and if these factors interact, what combination of emphasis and colour is best. The latter is called interaction effect. If a pre-test were given this would be a repeated measures 2×3 factorial design.

Other designs

The variety of designs is limited mainly by one's ingenuity. A number of designs have been borrowed from agriculture such as the Latin and Graeco-Latin square and the split plot designs. These and others are described in Bow *et al.* (1978), Cochran (1992), Fisher (1966), Kirk (1982) and Winer (1971).

experimental economics

There was a time when the conventional wisdom was that, because economics is a science concerned with complex, naturally occurring systems, laboratory experiments had little to offer economists. But experimental economics has now become a well-established tool of economic research. The initial impetus for this transformation came from studies of individual choice behaviour. As economists focused on microeconomic theories which depend on individuals' preferences, the fact that these are difficult to observe in natural environments made it increasingly attractive to look to the laboratory to see if the assumptions made about individuals were in fact descriptive of their behaviour. In 1944 the publication of von Neumann and Morgenstern's *Theory of Games and Economic Behavior* accelerated the interest in experimentation. The expected utility theory they presented gave a new focus to experiments concerned with individual choice, while the predictions of game theory—and how these depend on the rules of the game—sparked a wave of experimental tests of interactive behaviour. This has blossomed into large literatures on topics as diverse as bargaining behaviour, the provision of public goods, co-ordination and equilibration, and the effects of different rules of market organization.

Formal tests of economic theories of individual choice go back at least as far as L.L.Thurstone (1931), who used experimental techniques common in psychology to investigate whether the indifference curve representation of preferences could coherently organize individuals' choices (he concluded that it could). Expected utility theory made more pointed predictions which allowed more powerful tests, and while some early experiments (e.g. Mosteller and Nogee 1951) supported the conclusion that utility theory could serve as an adequate approximation of behaviour, others, such as Allais (1953) identified systematic violations of utility theory. There have since been hundreds of experiments designed to explore further systematic violations of utility theory, and of the alternative choice theories that have been proposed to account for various parts of the experimental data. Considerably less experimental work has been devoted to assessing the extent to which utility theory is or is not an adequate approximation on different domains, and given the importance of utility theory in economic theory generally, this probably deserves more attention. Camerer (1995) gives a comprehensive survey.

An early game theoretic experiment, conducted by Melvin Dresher and Merrill Flood in 1950 (1958), first introduced the much studied game which subsequently came to be called the Prisoner's Dilemma. They observed that, even in a game with a unique equilibrium, the observed behaviour may deviate from the game theoretic prediction. But these experiments also confirm the game theoretic prediction that the incentives for individuals to act in their own interest may in some circumstances make it difficult to achieve the gains available from co-operative action. One body of experimental research which pursues this investigation concerns the provision of public goods; this literature is surveyed by Ledyard (1995).

A different kind of problem emerges in games having multiple equilibria, in which the players must co-ordinate their expectations and actions. Early experiments on co-ordination were reported by Thomas Schelling (1960). Bargaining presents an important class of problems in which co-ordination of expectations is of the essence, and it is a subject in which there has been considerable interplay between theory and experiment. Surveys of modern experiments concerning co-ordination and bargaining may be found in Ochs (1995) and Roth (1995a).

Experiments are particularly useful for isolating the effects of the rules of the game by which markets are organized. (For example, cattle and flowers are auctioned by different rules, but are also very different commodities, so one cannot isolate the effect of the different rules by relying only on field studies of cattle and flower auctions.) Ghamberlin (1948) introduced a design, now widely used by experimenters, to create markets for artificial commodities in which the reservation prices of buyers and sellers can be controlled by the experimenter. Chamberlin's design permits experiments in which different rules of market organization (e.g. different forms of auction) can be compared while holding all else constant. Kagel (1995) surveys the large modern literature on auctions, Sunder (1995) considers markets for commodities (such as financial securities) in which information plays a dominant role, and Holt (1995) surveys experiments in industrial organization generally.

Much modern work has gone into understanding when equilibrium predictions will be descriptive, and when they will not. Experimental evidence has helped spark an interest in theories of learning and adaptation, in contrast to theories of static equilibrium. A general overview of experimental economics, including details of its early history, may be found in Roth (1995b).

externalities

Economic externalities are (positive or negative) goods or services generated by an economic activity whose costs or benefits do not fall upon the decision-taking agent. Pollution is a leading and important example. They may, alternatively, be thought of as residuals, the difference between 'social' and 'private' costs and benefits. The divergence was first popularized and elaborated by Pigou in *The Economics of Welfare* (1920) and is believed to be a major reason for market failure: for example, the market will overproduce goods with high external costs. For that reason a main principle of cost-benefit analysis is that *all* costs and benefits, no matter to whom they accrue, should be included. Popular discussion rightly emphasizes external costs associated with production, but one should not entirely ignore positive production effects (apples and honey) or effects on the consumption side, either positive (attractive dress) or negative (radio noise).

Various policies are, in principle, available for dealing with externalities. For example, the extent of an activity may be *regulated,* as in the case of the discharge of industrial effluent into estuaries. Using partial equilibrium analysis the regulation should set the amount of discharge at an optimum, that is, where marginal social cost and benefit are equal to one another. This is, of course, very difficult to calculate, so rough rules of thumb are used instead. Economists often argue for the direct use of *pricing:* the agent is

charged a tax (or paid a subsidy) equal to the value of the externality at the margin. The congestion tax is an example of this. Such taxes and subsidies are referred to as Pigouvian: they are intended to internalize the externality. Internalization may also come about spontaneously by the *merger* of two units inflicting large externalities upon one another (as in industrial integration).

The tax-subsidy solution is often objected to on the ground that it is open to injured parties to bring an action in tort against the offending agent. If agents know this to be the case, they will take expected compensation for damages into account and externalities will automatically be internalized. On this view not only would Pigouvian taxes not be needed but also they would, if imposed, lead to an over-restriction of activity (Coase 1960). Property rights are seen to be crucial, as they define rights to compensation: defenders of the market system therefore argue that externalities do not constitute market failure provided that property rights are adequately delineated. The direction of compensation naturally depends on the initial distribution of legal rights.

The alternative solutions are closely related to one another. Take the case of a major oil spillage which fouls beaches and destroys fishing and wildlife. If spillages are to be 'banned' the fine must be at least equal to the Pigouvian tax. If there is to be a legal contest, it will have to be fought between states and oil companies rather than through improvised groups of holiday-makers, workers in the fishing industry and wildlife enthusiasts. And fines/compensation must not give an outcome which is totally unreasonable in relation to the optimum (possibly, though not certainly, zero) amount of spillage.

factors of production

Factors of production, or (in more modern terminology) 'inputs', are the things which are used in the process of producing goods or services. An early typology of inputs was provided by Jean-Baptiste Say, whose classification separately defined land, labour and capital as factors of production.

A distinction is often made between flow inputs (which are embodied in the final product and cannot therefore be used more than once in the act of production) and stock inputs (which can be used repeatedly). The distinction is somewhat artificial, however, because stock inputs characteristically depreciate in value over time, and this depreciation can itself usefully be regarded as a flow.

All factors of production can, in principle, be hired by the producer. In a non-slavery society, labour can be hired—at a per period cost defined by the wage—but not bought. Capital may, at the discretion of the producer, be bought rather than hired; it remains the case, however, that producers implicitly pay a rent ('user cost') on the capital under their ownership, because by using that capital they forgo the opportunity to hire it out to a third party. Land, likewise, may be bought or rented; in the former case producers implicitly pay a rent in order to use land as a factor of production, because they forgo the opportunity to earn a landlord's income.

Labour will in general be hired by a profit-maximizing producer up to that point where the wage is just offset by the value of the marginal product of labour. In a similar fashion, long-run equilibrium requires that capital should be employed up to the point where the user cost equals the value of the marginal product of capital. A similar condition applies to land. A change in production technology which disturbs the productivity of any factor of production will generally alter the equilibrium employment of each input. Likewise a change in the price of any input (for example, the wage or the user cost of capital) will, so long as inputs are to some degree substitutable, cause a change in the mix of factors of production employed.

Simple models of the production process typically employ two factors of production, often labour and capital. The first of these is defined to be variable in the short run, while the second is assumed fixed. In effect, the minimum timescale within which the latter input can be varied defines the length of the short run. Given information about the producer's objective function, this allows a distinction to be drawn between the behaviour of the producer which is optimal in the short run and that which is optimal in

the long run.

The precise manner in which factors of production are converted into outputs is modelled by means of a production function. The simplest type of production function in common use postulates that the production of a single type of output is determined by a geometric weighted average of the various inputs employed. This is known as a Cobb-Douglas production function, the parameters of which may statistically be estimated by means of a regression which is linear in natural logarithms. The Cobb-Douglas function can be shown to produce downward sloping and convex isoquants—a characteristic which is conventionally deemed attractive because it establishes the existence of unique solutions to the constrained optimization problems characteristic of neo-classical economics.

The more general constant elasticity of substitution (CES) and transcendental logarithmic (or 'translog') production functions have become increasingly popular among applied economists. The Cobb-Douglas is a special case of both of these. The translog function adds to the list of explanatory variables used in a Cobb-Douglas type regression a full set of logged quadratic terms and interaction terms between the logged inputs.

An appealing property of all the production functions described above is their implication that the marginal product of variable inputs (eventually) falls as the employment of those inputs increases. This ensures the finiteness of the equilibrium level of output of the individual firm, regardless of demand conditions. The translog specification of the production function is particularly appealing because, depending upon the estimated parameters, it is consistent with the popular presumption that the long run average cost curve is U-shaped.

The production technology described by these functions is closely related to the way in which the producer's costs are determined. Given the prices of the various factors of production, producers use their knowledge of the production technology to decide, for each level of output, what mix of inputs optimizes their objective function (usually profits). Once this input mix is chosen, the total cost of production at each output level is straightforwardly calculated as the product of the vectors of input prices and input quantities.

It is only recently that economists have begun rigorously to tackle the analytical problems posed by firms which produce many distinct types of output. Multi-product firms of this type might exist because of synergies which arise from the co-ordinated production of different goods and services. These synergies may in turn arise from characteristics possessed by inputs which can simultaneously be put to more than one use. In the case of firms which produce more than one type of output, output cannot be represented as a scalar, and so the technology of production is best understood by investigating the dual problem: that is by estimating a (quadratic or CES) multi-product cost function.

The simplistic view of labour as a variable input has been relaxed in recent work which views skilled labour as an investment in 'human capital'. Such an investment takes time, and so in the short run skilled labour may be fixed. However, where more than two inputs are employed, the distinction between the short and long run becomes blurred. Indeed, an issue which has remained underdeveloped in the economics research programme concerns the application of methods commonly used in the literature on product

differentiation to the case of heterogeneous factors of production.

family

In the mid-third of the twentieth century, anthropologists and sociologists spent much time and energy debating the universality of the family, specifying its functions and undertaking comparative analysis of different family systems. At the end of the century, such concerns with the naturalness and consequent inevitability of the family seem somewhat barren, though moral arguments about which forms of family life are legitimate and which pathological remain politically contentious. While all societies are necessarily concerned with matters of biological and social reproduction, the social and economic organization of this reproduction is inherently bound with the wider social and economic formation in which it occurs.

Indeed the concept of the family can be recognized as a construction which developed its potency with modernity, if not industrialization. This was implicit in sociological debates about the impact of industrialization on the dominant family system, often simplistically expressed as a shift from an extended form to a nuclear one. That is, under the conditions of late nineteenth and early twentieth-century industrialization, the family seemed to be developing in an increasingly uniform and predictable fashion, marked by a gendered division of responsibility and a higher commitment to spouses and dependent children than to other kin (Harris 1983). Under these conditions the family came to take on particular meanings, though not ones which necessarily resonated very strongly in other types of society where social reproduction was organized in a different fashion. Inherent here too is the notion of family as itself complex and variable, with the term being used in both academic discourse and everyday talk in a variety of different ways depending on context.

Two broad strands of meaning are evident in much routine discussion of the family. First, there is the sense of family as a subset of an individual's kinship universe. That is, by family we refer to those who are linked by blood and marriage to us, though the linkages which are included in any particular instance is an open matter. Second, the term family is often used as a virtual synonym of household. Here kinship linkage remains important, but in addition there is implicit reference to a shared housekeeping and a

common domestic economy. A main distinction behind the variable uses of the term family concerns the boundaries that are constructed delineating those who are family from those who are not. The closer the genealogical link, the more likely an individual is to be referred to as family, though genealogy itself is not the only factor. What also comes into play is the relative strength of the consequent social relationships and the nature of the obligations which have developed.

Family life has become rather more complex in the latter part of the twentieth century than it had been in the earlier part. Whereas for much of the century it was appropriate, albeit with a degree of caution, to conceive of a broad uniformity and standard order in family relationships, this is now a rather less convincing characterization. Within most western societies at least, the latter part of the twentieth century has seen significant shifts in the demography of family life, with consequences for the permeability of family boundaries and the nature of some family obligations. Thus whereas social scientists once talked of the 'family cycle', meaning a common route through a structured series of family phases involving different responsibilities and opportunities, this has given way to the idea of 'family course', implying the existence of phases which make differential demands on the individuals involved, but which do not necessary entail a tidy progression. For example, the increase in rates of divorce, cohabitation, births to unmarried mothers, and reconstituted families throughout the western world have resulted in more diverse family pathways emerging than in the recent past.

Equally, the same changes have led to networks of family relationships becoming more complex, with greater variation and less clarity about who can appropriately be regarded as family and how such relationships should properly be framed. In particular, the increased incidence of divorce and remarriage has meant that many more people have ex-spouses, absent parents, step-parents, step-siblings, half-siblings, and the like. The specific family circumstances of these relationships are themselves highly variable, for instance, in terms of whether step-parents or half-siblings are co-residential, and whether ex-spouses continue to parent children in an active way. Moreover the relationships have not been socially institutionalized, in the sense that there is little societal guidance as to how they are most appropriately patterned. Furthermore, marital separation and divorce often have ramifications for other family ties, affecting for example the form and content of grandparent, aunt/uncle and cousin relationships.

If in this sense the boundaries constructed around the family are more permeable than they once were, there is still a strong element within western cultures of the family being an essentially private institution. Indeed theories about the growing privatization of the family with industrialization are common, though not without their difficulties (Pahl and Wallace 1988). This covers more than ideas of a shift from extended to nuclear family forms; it also implies that families, predominantly in the sense of households, have managed to construct physical and symbolic bound aries around themselves which ensure that what goes: on in the domestic arena is outside the gaze or control of others. Although privacy has long been sought by families in all classes, general improvements in the material conditions of home life have encouraged the self-containment of aspects of family life, with reduced involvement between those who happen to be neighbours (Allan 1985). At the same time though, the state through its various welfare measures has become more concerned with defining and monitoring appropriate standards of family

behaviour. This applied particularly with regard to children where a range of welfare professionals—health visitors, social workers teachers, doctors—play a part in regulating families especially those seen as pathological or potentially so (Donzelot 1979).

Some of the most interesting research on families has focused on the issue of reproduction, in social and economic senses more than the biological The division of household labour, the changes and continuities there have been in this, and its impact on gender inequalities, have been much analysed Increased recognition has been given to the unpaid economic, as well as emotional and supportive, work which family life entails (Morris 1990; Pahl 1984). Thus the production of a particular standard of living for a household and the transformation of wages into well-being warrant analysis just as much as other forms of work. The social and economic relationships that this work involves have often been depicted as somehow natural because of their family basis, but in reality they contain issues about the social distribution of power and inequality as much as any other system of exchange does (Delphy and Leonard 1992).

In addition, families play a significant role in material and cultural reproduction across the generations. In particular, despite changes there have been in patterns of social mobility, the inheritance of private property and the transmission of 'cultural capital' (Bourdieu 1973) within families remains important in the maintenance of advantage and disadvantage. Equally numerous studies have demonstrated the continued link between health and educational success and the material conditions of home and family life (Graham 1993). Put simply, family environment, itself shaped by structural parameters whose roots lie elsewhere, has significant impact on the perpetuation of social and economic inequality.

For this and other reasons, the well-being of the family remains a highly charged political and moral issue throughout the western world. Matters like domestic violence and child abuse, the impact of unemployment and poverty on families, the problems facing lone-parent households, especially those headed by young, economically disadvantaged women, and the increase in cohabitation and step-families, have all led to a heightened consciousness of the ways in which the family is changing. Within this context, it becomes even more important to recognize the socially constructed character of the family. Family life has never been static; the forms it takes have always been influenced by the socioeconomic structures within which it develops. The significant changes occurring in family patterns in the late twentieth century need interpreting in this light rather than in a socially disconnected fashion.

family history

Family history as a research field emerged in the 1950s as part of the growth of interest in economic and social history. Historians seeking information on the family sought to exploit a multitude of sources. Reference to legal texts, court cases, choice of forename, paintings of family groups, medieval treatises and excavations of private dwellings have enabled inferences to be drawn about the nature of family life in ancient Greece and Rome and the Middle Ages (Gardner 1986; Gotein 1978; Humphreys 1983; Klapisch-Zuber 1985; Rawson 1986; see also Ariès 1962, but see Burton 1989 for a critique of Ariès's interpretation of the representations of children in medieval and Renaissance art).

The largest number of people involved in family history, however, are those who devote their leisure time to researching the history of their own families. Many family historians are no longer content just to collect names and dates, but try to study their ancestors in their context by learning about their occupations, friends and neighbours. A diverse literature has been produced by and for these family historians, providing both introductory and detailed guides, transcriptions and indexes of the most useful sources (Federation of Family History Societies 1993; Hey 1993). The Federation of Family History Societies also publishes a bi-annual newsletter, *Family History News and Digest,* detailing both activities and publications. In 1994 there were over eighty family history societies active in England and Wales.

Writing in 1980, Anderson identified four principal approaches adopted by historians when writing on the family: psychohistorical, demographic, sentiments and household economic (Anderson 1980). Each approach has had both champions and detractors. Psychohistorians promise the closest perspective on the motivations, conscious and unconscious, of past generations, but many of their conclusions have not been accepted by other historians (Anderson 1980; de Mause, 1974). Changes in attitudes to relations between parent and child, and to marriage, sex and privacy have been investigated by historians of the sentiments school, primarily using a range of literary sources. This has resulted in excessive attention to the lives of the elite, who produced the bulk of the literary records, an assumption that their behaviour would sometime later be adopted by the rest of society, and a tendency to focus on the origins of aspects of the family which are of contemporary concern, rather than considering the role of the family in a specific time and place (Stone 1977; for a criticism see Laslett 1987).

Demographic historians, by contrast, have been much more obviously constrained by

the nature of the surviving evidence. In measuring what can be measured, most attention has been devoted to the form and structure of the household, age at first marriage, patterns of child-bearing and illegitimacy (Hanley and Wolf 1985; Laslett and Wall 1972; Mitterauer 1983; van Poppel 1992; Shorter 1976). Weaknesses with this approach are the inability to identify the attitudes which might account for the observed behaviour. Anderson argued, for example, that a similarity in age between husband and wife was insufficient proof of the presence of companionate, more egalitarian, relationships within marriage, and that the form of the family and household might be more appropriately viewed as the by-product of economic and social forces, rather than having any particular social meaning for the family members concerned (Anderson 1980).

The attempt to relate family forms to wider economic processes is represented by the work of historians who have adopted the household economics approach to study the significance for the family of inheritance customs and practices, and the work patterns of peasant and proletarianized populations. Some of the results have been surprising, for instance, the absence of a correlation between early marriage and partible inheritance and between late marriage and impartibile inheritance. Historians have also discovered a considerable degree of continuity in family patterns between pre-industrial and industrial societies (findings summarized in Anderson 1980). However, as a rule, the household economics approach is better adapted to the examination of distinct microeconomic environments rather than broader economic processes, due to the difficulty of measuring the indirect, as opposed to the direct, effects of economic change. Other problems arise because of biases in the nature of the surviving data, for example, transfers of property taking place after death are usually much better recorded than are lifetime transfers. Nor have historians favouring the household economics approach been any more successful than household demographers in measuring the extent to which cultural factors helped to shape family forms. The acknowledgement of the limited explanatory power of demographic and economic factors as determinants of family patterns has forced cultural factors on to the research agenda (Alter 1991). However, no way has yet been found to measure the impact of these cultural factors other than by assuming that these account for all of the variation in family patterns that cannot be explained in any other way (Ruggles 1987).

Few attempts have been made to integrate the various approaches to the history of the family. Hareven's (1987) assessment of a decade's work in family history largely ignores the sentiments and psycho-history approaches. Burgière *et al.'s* (1986) two-volume history of the family, drawing on a wide range of source material, is an effective summary of much research but provides little in the way of critical comment. Other studies have considered the power of key institutions, such as the church and the state, to determine family behaviour. It has been argued, for example, that the medieval church framed its marriage laws in such a way that land would accrue to the church from families left without heirs (Goody 1983; for a criticism see Bonfield 1991). The border between the spheres of influence of the eastern and western church, in conjunction with the pattern of colonization in early medieval times, has also been seen as influencing the perduring boundary between eastern and western Europe in terms of marriage ages and household patterns, with earlier age at marriage and more complex households located in eastern areas (Mitterauer 1994). In England, the Poor Law alleviated, if it did not entirely

remove, disparities in income between men and women and young and old, and families with many children and between families with few (Henderson and Wall 1994). To minimize expenditure, the Poor Law authorities would even on occasion actively promote the formation of households in which a younger recipient of poor relief would be paid to provide care to an older one (Sokoll 1993).

A great variety of family relationships could exist within the framework allowed by any one legal system. Historians now realize that in addition to the major differences in family patterns between eastern and western Europe, there was also extensive variation regionally and locally, and between richer and poorer and high and low status families, reflecting in particular the extent to which families functioned as welfare and work units, and the work patterns and status of women.

family therapy

Family therapy is both a theory of family functioning and a treatment technique for troubled couples or families. The theory maintains that the family is a functioning and cohesive system with rules or patterns, which it maintains when faced with stress. Thus the family system is different from and greater than the sum of its parts and must be observed as a whole in action. Malfunctioning or pathological family systems often lead to individual symptomatology.

To understand and change the family, the therapist requires certain information, including details about its culture, ethnicity and socioeconomic status, the facts about each member, and the family's history and life-cycle phase. Each family has its own traditions, marital contracts, myths, secrets and loyalties to the past. Individuals in the family have their own dynamics, expectations, hopes and life experiences. Direct observations are necessary in order to assess the roles, coalitions, hierarchies and alliances between members, the communicational patterns and their clarity, the patterns of rewards and punishments, and the distribution of power. Finally, the experimental and ethical aspects must be ascertained. This last step involves assessing the empathic experience of the family from the perspective of each member, learning whether they have been treated fairly and justly and what debts and credits they have *vis-à-vis* other family members.

The family therapist uses these observations to form a therapeutic alliance and meets with the appropriate family members to design suitable interventions in order to change family functioning. In maximally distressed families, interventions should initially be aimed at preventing physical harm to members, strengthening the parental-marital

coalition, appropriately controlling the children, and promoting suitable distance between over-involved pairs. Other goals include encouraging clear and open communication, exploring mistaken attributions made of members, particularly as these are related to the past, and rebalancing the family towards fairness and justice.

Three techniques are commonly employed. First, the exploration of projective identification, where disowned aspects of the self are attributed to others, who are both related to as though the attribution was correct, and are often pressured to act in accordance with it. Second, the assignment of tasks to the family with the purpose of altering behavioural reinforcements, interrupting malfunctioning aspects of the family system, particularly when the family resists change, and providing a new and novel experience. Third, helping the family to find ways of redressing past injustices and finding new and fairer ways of functioning.

Family therapy is considered more effective than individual treatment when the problems involve a dysfunctional marriage, and at least as effective in the treatment of disturbed children and adolescents, particularly if the problems are neurotic or psychosomatic. Psycho-educational work with families has been found valuable in preventing relapse in schizophrenia. The family is educated about the disease, its course and treatment, and is helped to attend to and comment on the patient's behaviour rather than to criticize thoughts and feelings. Finally, meetings with the families of individual psychotherapy patients have been found to be a useful adjunct to the treatment of adults in marital difficulties.

fantasy

Fantasy, our capacity to 'give to airy nothing a local habitation and a name', has long intrigued poets, play-wrights and painters but only during the twentieth century has the phenomenon become a formal area of scientific inquiry in psychology. In current usage the term is almost synonymous with daydream. Within the area of experimental or clinical study, however, the term fantasy has a broader significance, as it deals not only with imaginary activity spontaneously produced as part of the ongoing stream of thought (daydreams) but also with products of thought elicited upon demand from a clinician in

response to inkblots or ambiguous pictures. It also refers to literary or artistic representations of the mental processes.

Fantasy refers to the human being's remarkable ability to create an 'as if' world either spontaneously or upon demand. It is possible that people at one time were more prone to regard their own fleeting imagery or brief daydreams as actual visions, as omens, or as appearances of deities, much as they responded to nocturnal dreams (Jaynes 1977). Prophetic visions, such as Ezekiel's 'wheel' or John's Apocalypse, probably represent literary expressions of elaborate daydreams or fantasies used for expository or hortatory purposes.

In 1890 William James in *The Principles of Psychology* devoted portions of several chapters, including the famous one on the 'stream of thought', to issues closely related to fantasy processes. James called attention to what he termed the reproductive and memorial facets of imagery, or the degree to which the image is of an object recently perceived or one called forth from the distant past. The fantasy presumably may represent a response to a stimulus perceived momentarily which triggers off a complex associative process in the ongoing stream of thought. In James Joyce's novel *Ulysses* the young Stephen, gazing seaward from his tower apartment, first sees the waves whose foamy curves remind him of a childhood song, then of his mother's death, his refusal (as a lapsed Catholic) to pray, and finally these associations generate a vivid fantasy of her confronting him in her graveclothes to denounce him (Singer 1994).

Psychoanalytic contributions

Freud's elucidation of the structure and interpretative possibilities of the phenomenon of nocturnal dreaming, based largely on remarkable self-observation and intensive clinical work, also led quite naturally to explorations of other dreamlike phenomena, such as daydreams. Freud (1962 [1908]; 1962 [1911]) speculated on the psychological significance of the daydream in papers like 'Creative writers and daydreaming'. The free-association process of psychoanalysis itself also led to patients' frequent reports of memories of childhood fantasies or recent daydreams. The most important fantasies from a technical psychotherapeutic sense were those involving the relationships between analyst and patient. Throughout the twentieth century psychoanalysts have made regular use of reports of spontaneous fantasies and published many papers in which myths or popular stories and literature were interpreted as outgrowths of fantasy.

Projective methods

With the indications of the widespread nature of human fantasy processes emerging from psychoanalysis and other psychiatric efforts, there was gradually an attempt to find procedures that could elicit fantasies from individuals providing significant diagnostic evidence ultimately for treatment plans and specific therapeutic interventions as well as for research purposes. The most prominent projective methods were the Rorschach Inkblots and the Thematic Apperception Test. They have been subject to literally

hundreds of research studies which to some degree have also contributed to general personality research and to diagnostic understanding.

The *Rorschach Inkblots* represent an attempt to use spontaneous associations made to the ambiguous nature of the blots as a means of identifying structural properties of the personality, such as tendencies towards imaginativeness, emotional impulsivity, indications of anxiety or cognitive organization and self-control. Hermann Rorschach observed that associative responses to the ambiguous ink blots which involved reports of humans in action ('two men playing patty cake') were linked systematically not only to a considerable tendency to engage in fantasy but also to a capacity for self-restraint and inner control. Extensive research studies have generally supported this observation (Singer and Brown 1977). These so-called M responses to the Rorschach Inkblots do seem to reflect an adaptive capacity for restraint, self-knowledge and creative thought.

The Thematic Apperception Test, in which the respondent makes up stories to simple pictures (such as a boy staring at a violin) that are somewhat ambiguous, has also proven to be a significant indicator of fantasy. This measure has been perhaps even more precisely analysed in the work of David McClelland because of its linkage to motivation following its original development by Henry A.Murray of Harvard University. The scoring of these fantasy-like stories for indications of motives such as *achievement, power, affiliation* and *intimacy* needs has proven to predict the social behaviour of individuals in other settings to a considerable degree (McClelland 1961; 1992).

Current research methods and theoretical considerations

Psychologists under the influence of behaviourism were at first reluctant to study ephemeral thought processes or fantasies. Since the 1950s there has been an accelerating interest in such inner processes, furthered by the emergence of many improved methods for studying the nature of fantasy processes as they emerge in the course of normal ongoing thought (Klinger 1990; Singer 1966; 1993). The methods currently in active use by researchers include questionnaire surveys; self-recordings of daydreams under controlled conditions; laboratory studies of daydreams and fantasies that emerge during a variety of simple or complex task performances; psychophysiological measurement of brain functions or eye movements during the process of creating fantasies; and the assessment of fantasies as they occur naturally through having individuals carrying paging devices or bleepers which signal randomly when an individual must immediately report ongoing thought or fantasy.

What have we learned by the application of these methods? The questionnaire approaches allow us to sample the self-reports of hundreds of individuals about the frequency, content and patterns of their fantasy; it is possible to conclude that daydreaming and the generation of fantasies is a normal process, one that occurs almost daily in every individual. Three general styles of fantasizing have been identified: one involves more positive and future oriented explorations, a second more guilt-ridden or unpleasant and frightening considerations of past events or future possibilities, and the third pattern involves the ability to sustain elaborate fantasies or to organize one's private imagery into consistent story-like structures. Questionnaire studies have also brought

various cultural differences in the content of fantasies with such differences often reflecting phenomena such as the relative upward mobility of a sociocultural group in this society. Sexual fantasies are nearly universal in western society if, however, not nearly as frequent as one might think from popular literature or film. There is no evidence that fantasy is in itself a sign of serious emotional disturbance; on the contrary severely disturbed individuals such as schizophrenics or extremely impulsive or aggressive individuals are often characterized by less varied or rich fantasy lives and more by single-minded and limited fantasy tendencies (Klinger 1990; Singer 1976).

Laboratory studies have shown the persistent and ubiquitous nature of human fantasy, even under conditions in which the individual is performing a relatively demanding task. For example, individuals may be sitting in small booths listening to signals presented to them via earphones and must be constantly pressing buttons to show that they comprehend the targeted signals as they appear as fast as one per second. If they are interrupted every fifteen seconds and must report on extraneous thoughts it turns out that even while processing signals quite accurately over an hour's time, they still generate a fantasy as often as 50 per cent of the time. It is possible to show that certain types of individuals, who on questionnaires report more fantasy tendencies, are often more inclined to report fantasies during such precisely measured laboratory interruptions.

Other types of laboratory studies have demonstrated that when individuals are engaged in a fantasy activity their eyes tend to become unfocused and relatively motionless, particularly if there are movements or other visual signals presented in front of them. This would suggest that the visual images, which are the predominant characteristics of human fantasy for most people, involve the same brain system as that of normal vision when processing externally generated stimuli. There are also research suggestions that particular types of brain waves, such as alpha rhythms or theta rhythms, may be the ones most prominently in evidence during waking fantasy activity.

Studies making use of paging devices are able to capture the way that fantasies occur during ordinary day-to-day activities. Extensive work in this area has been carried out especially by Russell Hurlburt, Mihailyi Csikszentmihalyi and Eric Klinger (1990). These studies also show how closely daydreams or fantasies are linked to fundamental motivational processes called 'current concerns', both short and longer term unfulfilled intentions.

Early theorizing about the nature of fantasy processes were strongly influenced by Sigmund Freud's important insight which linked the human being's capacity to delay gratification, a vitally significant step in our adaptive development, to our imaginative capacity. While certainly, as Freud suggested, the daydreams of the poet can be transformed into artistic productions, there is much less evidence for his position that only 'unsatisfied wishes are the driving power behind fantasies' or as he put it another time 'happy people never daydream' (1962 [1908]).

The research evidence since the late 1960s suggests rather that daydreaming is a fundamental human capacity which not only can reflect our unfulfilled wishes, of course, but also is inherent in our normal and healthy adaptive approach to exploring the physical and social environment through playing out mentally a series of possible scenarios. A more useful conclusion from current evidence would be that unhappy people are more likely to have unhappy daydreams and that people who are functioning effectively will be

characterized by a great variety of daydreams, the majority of which are more likely to involve playful and fanciful explorations of possible futures as well as some consideration of the negative alternatives in life. For the most part, most fantasy tends to be more realistic and geared to relatively mundane, practical issues in the individual's life.

Another influential conception introduced by Sigmund Freud was that the daydream or fantasy could partially discharge a drive, such as sex or aggression, and thus reduce the likelihood of an impulsive act. This *catharsis* theory has been extremely influential among literary individuals or persons in film and television. It is widely used as an explanation for encouraging children or adults to watch a variety of violent sports activities or films or encouraging children's exposure to violent fairy tales, with the notion that such exposure will reduce the likelihood of overt aggressive action. The evidence from dozens of laboratory studies of adults and children and from field studies of children exposed to violence in film and television overwhelmingly suggests that vicarious fantasy *increases* tendencies towards aggressive behaviour rather than reducing them. Our human fantasy capacity involves not a drainage of drive but a preparation for action. Those persons, however, who have developed a varied and complex imaginative life are often also more likely to recognize the unreality of many of their wishes; they can envisage a host of self-defeating consequences of impulsive action.

The current approach to fantasy and daydreaming processes casts such phenomena within a broader context of modern cognitive, affective and social scientific research. Human beings are viewed as continuously seeking to make sense of the novelty and complexity of their environment. They seek to organize and label experiences and form them into meaningful structures called schemata or scripts. At the same time they seek to anticipate possible futures. Fantasy represents the effort (influenced by religious symbols, folk legends, popular literature and, increasingly, films and television) of individuals to rehearse their memories and to create possible futures. Studies of early imaginative play in children point to the origins of the fantasy process where the dilemmas or cognitive complexities of the big world (social and physical) are miniaturized or re-enacted in a controlled play form. Adults continue this process privately through their mental imagery and interior monologues. Nocturnal dreams as well as daydreams reflect this continuing effort and suggest the inherent creativity of almost all individuals. Artists are especially adept at noticing such fantasies and incorporating them into their productions. Psychotherapists from a variety of schools have increasingly also encouraged the fantasy and imagery capacities of their clients as resources in the treatment process.

fascism

Of all the major terms in twentieth-century political usage, fascism has tended to remain one of the most vague. At the popular level, it has become during the past two generations little more than a derogatory epithet employed to denigrate a bewildering variety of otherwise mutually contradictory political phenomena. It has been applied at one time or another to virtually every single form of twentieth-century radicalism or authoritarianism, as well as many more moderate phenomena. More specifically, in terms of political regimes, there has developed since the 1930s a broad tendency to refer to any form of right-wing authoritarian system that is not specifically socialist as fascist. In this usage the Italian regime of Benito Mussolini is used as terminological prototype for all non-Marxist or non-socialist authoritarian systems, however they may differ from Italian Fascism or among themselves.

Rigorous scholarly and historical definition of fascism, however, refers to the concrete historical phenomena of the European fascist movements that emerged between the two world wars, first in the Italian Fascist and German National Socialist movements founded in 1919–20 and then among their numerous counterparts in many European countries. An adequate political and historical definition of fascism must define common unique characteristics of all the fascist movements in Europe during the 1920s and 1930s while at the same time differentiating them from other political phenomena. Such a criterial definition must specify the typical fascist negations, fascist doctrine and goals, and the uniqueness of fascist style and organization.

The uniqueness of fascism lay in its opposition to nearly all the existing political sectors, left, right and centre. It was anti-liberal, anti-communist (as well as anti-socialist in the social democratic sense), and anti-conservative, though willing to undertake temporary alliances with other groups, primarily rightist.

In their ideology and political goals, fascist movements represented the most intense and radical form of nationalism known to modern Europe. They aimed at the creation of a new kind of nationalist authoritarian state that was not merely based on traditional principles or models. Though fascist groups differed considerably among themselves on economic goals, they all hoped to organize some new kind of regulated, multiclass, integrated national economic structure, diversely called national corporatist, national socialist or national syndicalist. All fascist movements aimed either at national imperial expansion or at least at a radical change in the nation's relationship with other powers to enhance its strength and prestige. Their doctrines rested on a philosophical basis of idealism and voluntarism, and normally involved the attempt to create a new form of modern, self-determined secular culture.

Fascist uniqueness was particularly expressed through the movements' style and organization Great emphasis was placed on the aesthetic structure of meetings, symbols and political choreography, relying especially on romantic and mystical aspects. Fascist movements all attempted to achieve mass mobilization, together with the militarization of political relationships and style and with the goal of a mass party militia. Unlike some other types of radicals, fascists placed strong positive evaluation on the use of violence, and strongly stressed the masculine principle and male dominance. Though they espoused an organic concept of society, they vigorously championed a new elitism and exalted youth above other phases of life. In leadership, fascist movements exhibited a specific tendency toward an authoritarian, charismatic, personal style of command (the *Führerprinzip,* in German National Socialist parlance).

Radical rightist groups shared some of the fascists' political goals, just as revolutionary leftist movements exhibited some of their stylistic and organizational characteristics. The uniqueness of the fascists, however, lay in their rejection of the cultural and economic conservatism, and the particular social elitism of the right, just as they rejected the internationalism, nominal egalitarianism and materialist socialism of the left. The historical uniqueness of fascism can be better grasped once it is realized that significant political movements sharing all—not merely some—of these common characteristics existed only in Europe during the years 1919–45.

Fascists claimed to represent all classes of national society, particularly the broad masses. Marxists and some others, conversely, claimed that they were no more than the

tool of the most violent, monopolistic and reactionary sectors of the bourgeoisie. Both of these extreme interpretations are not supported by empirical evidence. In their earliest phase, fascist movements drew their followers from among former military personnel and small sectors of the radical intelligentsia, in some cases university students. Though some fascist movements enjoyed a degree of backing from the upper bourgeoisie, the broadest sector of fascist support, comparatively speaking, was provided by the lower middle class. Since this was one of the largest strata in European society during the 1920s and 1930s, the same might also have been said for various other political groups. In both Italy and Germany, a notable minority of party members were drawn from among urban workers. In Hungary and Romania primary social backing came from university students and poor peasants, and there was also considerable agrarian support in some parts of Italy.

A bewildering variety of theories and interpretations have been advanced since 1923 to explain fascism. Among them are, first, theories of socioeconomic causation of various kinds, primarily of Marxist inspiration; second, concepts of psychocultural motivation related to social psychology and personality and social structures; third, the application of modernization theory, which posits fascism as a phase in modern development; fourth, the theory of totalitarianism, which interprets fascism as one aspect of the broader phenomenon of twentieth-century totalitarianism; and finally, historicist interpretations, which attempt multi-causal explanation in terms of the major dimensions of central European historical development in the early twentieth century.

The only fascist movements to establish independent regimes of their own were those of Benito Mussolini (1922–43) and Adolf Hitler (1933–45), and only in the latter case did the movement's leader achieve complete power over the state. The other countries in which fascist movements were strongest were Austria (Austrian National Socialists), Hungary (Arrow Cross), Romania (Iron Guard) and Spain (Spanish Phalanx). In general, fascism had most appeal in countries defeated or destabilized by the effects of the First World War. Though fascist movements appeared in every single European country during these years (and also, very faintly, in the countries of the western hemisphere and Japan, paralleled by more vigorous expression in South Africa), very few of them enjoyed any degree of success. In nearly all countries anti-fascists were generally much more numerous than fascists. The extreme radicalism and calls to war and violence of the fascists limited their appeal, as did the non-rationalist, voluntarist nature of their doctrines. The great expansion of military power by Hitler's Germany was mainly responsible for the broader influence and historical importance achieved by fascism for a few years. Similarly, the complete defeat of Germany and Italy in the war condemned fascism to such total political destruction and historical discredit that all attempts at revival have enjoyed only miniscule support since 1945.

federation and federalism

A federation is a state organized on the basis of a division of power between general and regional governments, each independent within a sphere (Wheare 1946). The territory of a federal state is divided into units (for example, states, cantons, principalities, republics) which often coincide with distinctive geographic, cultural or historic divisions of the country. Many of the institutions of government are duplicated at the national and local levels with both levels of government exercising effective control over the same territory and population. Thus the citizens of a federal state belong simultaneously to two political communities: for those functions that are constitutionally assigned to the local level of government, the relevant community is the citizen's particular state, canton, province or republic; for functions assigned to the national government, the entire nation is the relevant community.

In the true federal state, both levels of government derive their powers directly from the constitution and neither is able to eliminate the other's jurisdiction. In this way a federal state is distinguished from a unitary state with territorial sub-units (such as counties, department, districts) that receive all of their powers by delegation from a central government. At the other extreme, a federal system of government should be distinguished from a confederation, or league of states, in which the central level of government receives all its powers from the member states and has no autonomous powers of its own.

The USA was the first modern nation-state to adopt a federal constitution. In the nineteenth century some of the new states of South and Central America (e.g. Venezuela, Colombia, Argentina, Brazil and Mexico) were organized on federal lines. But federal constitutions have been of less enduring significance there than in Switzerland (1848), Canada (1867) and Australia (1901) which, along with the USA, are the countries that have been practising federal constitutionalism without interruption for the longest time. Constitutions adopted by many of Britain's former colonies (e.g. India, Pakistan, Malaysia and Nigeria) incorporated the federal principle (Watts 1966). In Europe, the federal principle is prominent in the constitution of the Federal Republic of Germany. South Africa under its new constitution is to be organized as a federation.

The balance of power and of citizens' allegiance between the two levels of government is a dynamic element in the politics of a federal state. In some federations, the forces of centralization, especially when fostered by a single unified political party, may be so strong as to negate the autonomy of the local level of government. In others the forces of decentralization may be such that they lead to the break-up of the federal state (as in the

cases of the British West Indian Federation and Yugoslavia). For a federal system to endure, there must be significant independent political forces supporting each level of government. Federalism is a political movement advocating and working towards federation. A federalism movement can work in a centralizing or decentralizing direction. In the context of the European Union (EU), for example, federalists are considered to be centralizers as they attempt to increase the powers of EU institutions, while federalism in Belgium has had a decentralizing effect, converting a unitary state into a federal state.

feminist practice

The women's movement has challenged the conventional binary distinction between theory and practice, arguing there should be a symbiotic relationship between them. This relationship is best seen in terms of praxis: the unity of theory and practice in the enactment of small revolutions in the here-and-now. Manifestations of feminist practice can be seen in the overtly political arena, as well as in activities not conventionally seen as political. Scrutinizing feminist practice shows continuities between 'first wave' (Victorian and Edwardian) and 'second wave' (1960s onward) feminism; it should be recognized, however, that these are First World responses and that feminisms globally have taken rather different forms.

D*irect action* involves a variety of unlawful acts designed to bring to public awareness particular injustices. Thus, for example, the later stages of Edwardian feminism is associated with arson attacks against public buildings, while protests against pornography saw feminists firing sex shops in the 1970s.

C*ivil disobedience* includes behaviours on the threshold of lawfulness but outside of

correct behaviour. Here, for example, Victorian feminists shocked convention by publicly opposing the Contagious Diseases Acts, while 1990s lesbian feminists did so by abseiling into the House of Lords when it was debating Clause 28 of the Local Government Bill 1988, which made unlawful so-called 'pretended family relationships'.

P*ressure group politics* is now considered one of the main forms of political action within parliamentary democracies; Victorian feminists were among the pioneers of what was then considered to be outrageous behaviour. Then, feminists lobbied MPs and staged sitins in front of the House of Commons, while in the 1960s and 1970s feminists lobbied for the Sex Discrimination Act and for lawful abortion within the National Health Service.

S*elf-help* involves feminist provision of services which are either unavailable, or available only in unsatisfactory forms, from central and local government and their agencies. Thus Victorian feminists provided safe houses for abused children and refuges for women who were subject to violence from men, while 1970s feminists set up a national system of Rape Crisis Centres which offer help to women and children who have been subject to sexual abuse and sexual violence. Self-help provision is one means by which feminist practice has successfully challenged the boundaries of politics, moving attention away from the public of parliaments, armies and economies, and towards the private of everyday life and relationships. It has thereby also challenged dichotomized ways of thinking about the public and the private, for example, male violence and abuse within the family and also marital rape are now socially unacceptable, whereas earlier they were treated as part of private life in which state agencies should not interfere.

There are additional challenges to the boundaries of the political which feminism has pioneered; here again there are continuities between first-wave and second-wave feminisms. Thus the music of Victorian composer Ethel Smyth and the novels and essays of modernist Virginia Woolf, along with the poetry of contemporary black American feminist poet Audre Lorde and American artist Judy Chicago (best known for her exhibition 'The Dinner Party'), are powerful expressions of feminist practice as well as radical interventions in cultural representation. These and other examples demonstrate the strong feminist concern with acting against the grain, bringing together feminist theory and feminist practice in—and against—all aspects of social life. There has been an equally strong concern with living against the grain; examples here include living independently of men, sexually and also economically, and raising children in a non-sexist way.

In western societies, perhaps the most wide-reaching aspect of feminist practice is Women's Studies, which proposes a revolutionary remaking of knowledge. Its main areas of activity include critiquing the biases and omissions of 'malestream' theories and practices; filling the gaps occasioned by masculinist methodologies; reconceptualizing subject areas, theories and concepts from a woman-centred viewpoint; and challenging how knowledge is theorized and defined, thus politicizing questions of epistemology.

feminist research

The ideas covered by the term feminist research have changed emphasis considerably since the start of the feminist renaissance in the 1960s and 1970s. At least four sets of meanings and research practices are involved and are now coexistent. Feminists in the social sciences are likely to draw on ideas taken from each of these: they are by no means to be seen as mutually exclusive, nor indeed as necessarily antithetical positions.

Displacing the male knower

From the start of the feminist renaissance of the 1960s and 1970s, the sociology of knowledge issues involved in the feminist critique of the social sciences were clearly signalled. Academic feminism, at that time located predominantly in sociology, questioned the objective, rational, dispassionate and removed 'knower' and displaced *him* from his actually gendered—and raced and classed—position at the centre of knowledge-production. An associated critique of the dichotomies of positivism—subjective/objective, rational/emotional, science/life, masculine/feminine, male/female—is central to the arguments involved here, together with the insistence that feminist knowledge should be rooted in, and work out from, women's experiences.

'Hard' and 'soft' methods: recovering subjectivities

The feminist critique also focused on questions of method and methodology and it pinpointed particular methods—quantitative and 'hard' science ones—as central to the organizational apparatus of masculinism in the social sciences. This work proposed an alternative qualitative approach which would map subjectivities, the private as

counterposed by the public face of objective masculinity The arguments here focus on the question of method ('hard' v. 'soft') and its relationship to the devaluing of subjectivity as somehow innately—essentially—irrational and emotional, that is, associated with notions of 'science' and scientific method. However, this concern with recovering subjectivities can with hindsight be seen to leave intact the dichotomies of male/objectivity and female/subjectivity that other feminist work has been concerned to challenge.

Interviewing: feminism and friendship?

Arguments about 'recovering subjectivities' have particularly influenced feminist ideas about interviewing, seeing this as a method that would not only enable the investigation of subjectivities but also position research as a form of 'friendship' between feminist researchers and women research subjects. However, even as such ideas were first mooted, other voices raised the deeper issues of power involved. Nonetheless, throughout the 1980s interviewing and variants upon it, importantly including different styles of action research, dominated the feminist social science research agenda.

Epistemology and the politics of location

From the late 1980s on there has been a renewed interest in questions of epistemology, fuelled at least in part by the greater influence of feminist philosophy, including the epistemological aspects of a feminist politics of location. 'Who you are' makes a difference: to *what* is seen, to *what* cannot be seen, to *how* seeing occurs, and to what interpretational conclusions are drawn. Thus 'knowledge' and its constitution—including who are seen to be knowers, how knowledge is distinguished from mere opinion, how competing knowledge-claims are adjudicated, how gatekeeping across the boundaries between knowers and others occurs and by whom—has returned to centre stage within academic feminism.

Method, methodology and epistemology

As this overview suggests, there has been effectively no interest in the idea of developing a feminist method, in the sense of a distinct, unique feminist technique of research. Relatedly, there is no longer the view that particular methods are innately either good or bad. The distinction between method (or techniques), methodology (or broad theoretical and programmatic statements) and epistemology (or a theory of knowledge and knowledge-production) is useful here, for it shifts feminist debate about research away from method narrowly conceived and on to the far-reaching and fundamental questions of epistemology. That is, method is seen as the product of wider methodological and epistemological assumptions and stances, so that, for example, there can be positivist and masculinist interviewing, and feminist and radical surveys.

Developments in feminist epistemology

Subsequent developments in feminist epistemology have focused on overlapping debates concerned with method, methodology and epistemology, the relationship between mind and body, a feminist ethic, the category 'women' and feminist deconstructionism, ideas about essentialism and difference, and representation and history There are three related developments here worth particular comment.

Knowledge, method and praxis

Initially feminist writing on method/ology and epistemology addressed issues of particular concern to the social sciences. Subsequently, with the development of deconstructionist and post-modernist influences, the emphasis shifted first to the humanities, and then the debates became particularly marked by the concerns and language of feminist philosophy. One far-reaching consequence has been that the eminently practical and ethical issues that confront feminist researchers carrying out research in the social world, not just within and about texts, have, if not vanished, then been shifted to the epistemological sidelines. Indeed, questions of epistemology are becoming seen as part of feminist social theory and increasingly treated as the preserve of a small group of specialist elite theorists. What started as the practical questions of feminist praxis have become questions of feminist theory conceived in largely abstract terms. Thus for many feminist social scientists there is now an urgent need to return these debates back to the practical issues that face those who endeavour to carry out social research in feminist ways.

Epistemology and science

Writing about feminist research has from its inception been concerned with providing a critique of the natural sciences, seen as the paradigm case of science and its attendant binaries of subjectivity/objectivity, rationality/emotionality, and so on, while more recently the connections between these Cartesian binaries and the precepts of foundationalism elsewhere in academic life have been theorized. However, there have been feminist researchers and theorists working in the natural sciences as well as the social sciences and humanities, and writing attendant on their practices has developed along different lines. This latter strand of thinking has been more concerned with how feminist science can become possible, politically, ethically, methodologically and epistemologically. This latter strand of work, for example, has been concerned with the development of a feminist epistemological position that might heal the breach between 'heart, brain and hand' in the natural sciences.

Contra binaries

Academic feminism has provided a long-standing and stringent critique of binary ways of

thinking, from its 1960s and 1970s critique of sexism in the social sciences, through to the arguments of feminist deconstructionism with its critique of binary gender and thus of the defining terms of feminism itself. It is, then, paradoxical that some work concerned with feminist research and epistemology has left effectively intact the binary divisions used to separate epistemological positions and indeed to caricature the 'submerged' binary of each pair: realism v. idealism, and foundationalism v. relativism. Thus attempts to shift debate away from realist (there is a world of facts independent of any social construction) and foundationalist (knowledge can be founded in such external and independent facticity) claims within feminism have sometimes been caricatured as proposing radical idealist (only social construction exists, there is no reality) and relativist (no knowledge-claims are ever possible) positions. However, it has been argued that alternatives to binary thinking exist, in the form of a feminist approach which seeks knowledge and makes knowledge-claims, but which also sees knowledge as necessarily local and provisional. A similar position has been argued in relation to 'feminist fractured foundationalism', the view that what is seen as foundational coexists in social life with what is recognized as contingent, provisional and socially constructed, and that the exploration and analysis of such competing local knowledges should be the basis of academic feminist research and theorizing.

Where does 'knowledge' come from

At the basis of many of the debates sketched out here are two related questions: Can epistemology be ontologically based? Can epistemology ever be anything else? The first question expresses the view that feminist knowledge should be general and trans-situational and therefore not tied to the specificities of particular persons and places. The second question expresses the view (held by perhaps the majority of academic feminists) that there is no way of producing feminist or any other knowledge apart from through the minds of particular knowers, and that this politics of location requires a scrupulous attendance to unpacking the processes involved, including a detailed exposition of the processes of grounded feminist research.

As these two questions make clear, the feminist concern with research is actually a concern with the organizational and intellectual practices involved in knowledge-production, with assumptions about the definition and nature of knowledge, with how the relationship between being and knowing is theorized, and with the very conditions and constitution of science within the academy and its status *vis-à-vis* everyday life. These are of course the most fundamental questions and issues for all social science; it is noteworthy that they are central to academic feminism across the academic disciplines and occupy a particularly crucial place within feminist social science.

feminist theory

All variants of feminist theory tend to share three major assumptions: gender is a social construction that oppresses women more than men; patriarchy (the male domination of social institutions) shapes these constructions; women's experiential knowledge best helps us to envision a future non-sexist society. These shared premises shape a double agenda: the task of critique (attacking gender stereotypes) and the task of construction, sometimes called feminist praxis (constructing new models). Feminist theory focuses particularly on women's experiences of sexuality, work and the family, and so inevitably challenges traditional frameworks of knowledge and puts in question many assumptions of the social sciences, such as universalism.

Although foremothers like Mary Wollstonecraft (1759–97) are often claimed as feminist, the term feminism began to be used only in the 1890s (Offen 1988). In the twentieth century Virginia Woolf (1882–1941) and Simone de Beauvoir (1908–86) anticipate second wave feminism's attack on women's oppression. In the 1960s student and civil rights movements gave an impetus, shaping the topics and language of current feminist theory. As an identifiable area of the social sciences then, feminist theory dates from the 1970s with the publication of Kate Millett's *Sexual Politics.*

Feminist theory is, first, intensely interdisciplinary, ranging across customary subject divisions in the social sciences, including history, philosophy, anthropology, and the arts among others. Second, certain themes recur: reproduction, representation and the sexual

division of labour. Third, and most striking, are new concepts such as sexism and essentialism created to address absences in existing knowledge as well as the social discriminations these concepts describe. Fourth, women's subjective experiences are drawn upon to enrich scholarship and scientific theories. The starting-point is often consciousness raising where the personal can become political. MacKinnon (1989) argues that feminist theory is the first theory to emerge from those whose interest it affirms. Androcentric knowledge, feminist psychoanalysts claim, derives from masculine experiences of *separation* learned in childhood.

Since feminism developed at a time when the participation of women in the workforce was rising fast but while discrimination persisted, critics first focused on the sexism of language and of cultural and economic institutions. While intellectual ideas rarely present themselves in neat chronological order, the 1970s tackled the *causes* of women's oppression (capitalism/masculinity) describing society as a structure of oppressors (male) and oppressed (female). This moment is usually divided into *forms* of feminism (liberal, Marxist/socialist, cultural/radical). Liberal feminism argues that women's liberation will come with equal legal, political and economic rights, and Friedan attacked the 'feminine mystique' preventing women from claiming equality (Friedan 1963). More comprehensive Marxist/socialist assessments of economic gender exploitations were made by Juliet Mitchell (1966) and others. The key questions were: Did women form a distinct sex-class? How far is capitalism structured by patriarchy? By widening the Marxist concept of production to include household labour and childcare, feminists could highlight further sexual divisions ('domestic labour' debate) as well as women's unequal status at work ('reserve army of labour'). For example, Firestone (1970) argued that the 'material' of woman's reproductive body was as much a source of oppression as material inequality.

While dual systems theory argues that both capitalism and patriarchy construct gender, requiring a synthesis of Marxism with radical feminism, MacKinnon (1989) suggests that only radical feminism *is* feminism because it is post-Marxist. In opposition to a Marxist focus on *production,* cultural and radical feminists (e.g. Rich 1976) focused on reproduction and mothering and creativity. Although the labels cultural or radical are often misapplied, in general radical theorists take the view that sexuality, specifically male violence, is the cause of women's oppression condoned by the institutionalization of heterosexuality (see Dworkin 1981). This is the theme of Rich's (1980) milestone essay 'Compulsory Heterosexuality' which builds on de Beauvoir's premise that women are originally homosexual, to propose that lesbianism can be part of every women's cultural, if not physical, experience. This argument that 'lesbian' is shaped as much by ideological preferences as by explicit practice built on 'women identified women' and 'feminism is the theory, lesbianism is the practice' in second wave feminism.

A major rethinking of symbolic and social structures of gender difference was undertaken by French feminists *(écriture féminine).* They claimed that the cultural and gendered binaries man/woman, culture/nature always made 'woman' inferior (Cixous 1976). Binaries ignore women's fluid identity and the semiotic world of mother/infant bonding. American feminists drew on object relations psychoanalysis to locate the source of male power and fear of women in men's early experience of learning to be 'not the mother' (Chodorow 1978). These accounts of gender identity and objectification greatly

enriched feminist film and media study. The notion that there is a distinctive and gendered perception (the male 'gaze') is supported by the feminist standpoint theorists who challenge false notions of rationality and universalism in the social sciences (Harding 1986).

The 1980s saw a crucial shift in feminist theory when black feminist writers directed attention to ethnic differences. Criticizing the three form, or phase, typology (liberal/Marxist/cultural) as a white women's mental map which ignored the experiences of black women, they describe discrimination as an *interlocking* system based on race, class and gender (hooks 1984). They also introduced fresh theoretical arguments, suggesting, for example, that the family was not necessarily patriarchal but could be a site of resistance. Black theory derives from Afrocentric history, as well as from a 'both/or' reality (the act of being simultaneously inside and outside society) and has a particular view of mothering experience (Lorde 1984; Walker 1984).

These critiques of white essentialism were paralleled by feminist post-structuralist and post-modern critiques of structured systems of subjectivity. Drawing on ideas from deconstruction and discourse analysis, feminists argued that gender structures are historically variable and not predetermined. This led to what Barrett calls 'the turn to culture' and a renewed interest in cultural symbols (Barrett and Phillips 1992). Italian feminists, for example, created the term *autocoscienza* or the collective construction of new identities. Through cultural study many of these themes were brought together in feminist peace theory which argues that violence stems from traditional gender socialization. In opposition, pacifists created women-centred symbolic models of environmental action.

Feminist challenges to mainstream social science are diverse and influential, a central claim being that *all* science is motivated by gendered ideologies whether these are conscious or unconscious. The academic future of feminist theory is now more secure with the growth of women's studies.

fertility

Fertility (also referred to as natality) always refers in demographic usage to the achievement of live births. This is in keeping with its Latin etymological derivation from *ferre* (to bear) but in contrast to the verb, fertilize, which relates to conception. In English-language social science, the capacity to bear children is described as fecundity and the fact of giving birth as fertility. This is the reverse of the usage in French and other Romance languages. It also conflicts with much popular, medical and biological usage where infertility means not childlessness but infecundity or sterility (confusingly, the last can be employed in both senses even by demographers).

Fertility has long been identified with fruitfulness and productiveness, not only in terms of human reproduction but also with regard to the availability of game for hunters and the yield of crops. Indeed, the perceived relationship has played a major role in religion since palaeolithic times. The dependence of fertility upon preceding sexual relations has meant that both fertility and coitus play a central role in much of human culture and morality. In some cultures, particularly in the Middle East, the fact of pregnancy or childbirth to a married woman is usually the cause of pleasure, but should she not be married the reaction of her relatives might be so antagonistic as to result in her death and in great problems in securing the marriage of her siblings.

In spite of the biblical advice to be fruitful and multiply, and its mirroring in the adages of many pre-industrial societies, the maximization of fertility is usually constrained by other competing social objectives. Fertility is usually not favoured outside marriage partly because it may interfere with achieving the desired marriage. It may be discouraged soon after the birth of another child, because of the risk to health and life of both mother and children, or by grandmothers, because of the conflict between grandmaternal and maternal duties. Traditionally these constraints have been embedded in religion and mores rather than being expressed solely in terms of conflicting roles and danger to health.

Fertility may be expressed as a measure of the behaviour of a society, a couple or an

individual. In theory, reproductive measures are just as valid for individual males as females, but estimates for the former are rarely attempted because the fact of a man's fathering a child is less obvious to the community and may be unknown to the progenitor himself. The most meaningful measures of a woman's reproduction is the number of births she experiences between menarch (or puberty) and menopause. For the whole society, the average for all women is known as completed fertility. However, this measure can be determined only in retrospect, a quarter of a century after the peak in fertility for most women completing their reproductive spans, and societies frequently demand more immediate measures which are necessarily those for aggregate populations of different ages for a specified period (usually one year and hence described as an annual rate). The most common aggregate measure is the crude birth rate or the number of live births per year per thousand population. For national populations, this varied in 1993 from 53 in Malawi to 10 in Germany, Greece, Italy and Spain. The crude birth rate can prove to be an unsatisfactory measure in a society where immigration or other social changes have distorted the distribution of the population by sex or age, and more statistically refined measures relate births only to women of specified age or marital condition. The general fertility rate is the ratio of the births during a year to the total number of women 15–49 years of age. The relating of births to women of a specific age, or age range, for a specified period (usually one year), is termed the age-specifc birth rate (or fertility rate) and its sum over the whole reproductive age range is the total fertility rate, which in a society characterized by constant fertility over several decades, is an annual measure of the same magnitude as completed fertility. The total fertility rate ranged in 1993 from 7.7 in Malawi to 1.2 in Hong Kong, 1.3 in Italy and Spain and 1.4 in Germany and Macao. In former East Germany it was lower still, while in Asia levels of 1.5 were found in Japan, 1.6 in South Korea, 1.7 in Singapore and 1.9 in China. Attention may be confined to married women so as to determine marital age-specific birth rates and the total marital fertility rate. If only female births are related to mothers of each age, then the cumulative measure is known as the gross reproduction rate. Because for societies the effective measure of reproduction is not live births but surviving children, a measure known as the net reproduction rate has been devised. This may be defined as the ratio of female births in the next generation to those in this generation in conditions of constant fertility and mortality, and hence measures the eventual multiplication of societies' numbers from one generation to the next, once the age structure changes so as to conform with these stable conditions. If the society maintains a rate of unity for a considerable period (half a century or more in societies which were previously growing rapidly) it will become stationary, while a lower rate will imply eventually declining population size, and a higher rate, a growing population. In 1980, levels below unity were recorded by thirty-six European countries (the exceptions being Iceland, Ireland and Moldavia), seven East Asian countries (including China), seven Caribbean countries, and also the USA, Canada, Australia and Georgia. However, only Hungary also exhibited a decline in numbers (Bulgaria, Czechoslovakia, Denmark, Greece, Ireland, Italy, Latvia and Romania being stationary), because such rates have been achieved so recently that there are still disproportionalley more women in the potentially most fertile ages than would be the case in a population which had exhibited a net reproduction rate at or below unity for may years. Births within marriage may be described as nuptial or legitimate and those

outside as exnuptial or illegitimate.

The female reproductive span varies between women and between societies (or the same society at different dates), but approximately spans ages from around 15 years to the late forties. If fertility were in no way constrained, not even by the institution of marriage or by the practice of breast-feeding which tends to depress fertility, completed family size would be around 15 (Bongaarts (1982) employs 15.3 in his model). The total marital fertility rate of the Hutterites, a religious community opposed to deliberate fertility control, was in the western USA in the late 1920s at least 12.4—a level employed by Coale (1967) in his model—but this figure was almost certainly rising because of the reduction of the period of breastfeeding. Where breast-feeding is of traditional duration (two years or more) the following completed family sizes are found if deliberate control of marital fertility is not practised. First, where female marriage is early and widow remarriage is common, as among the Ashanti of West Africa (who practise only short periods of postpartum abstinence), around 8. Second, where female marriage is early and widow remarriage is discouraged, as in India prior to the family planning programme, around 6.5. Third, where female marriage is late and there are no strong feelings about widow remarriage, as in western Europe before the Industrial Revolution, around 6. The term natural fertility has been employed to describe the level of fertility, and its structure by female age, found in societies which do not deliberately restrict marital fertility (but in which sexual abstinence may be practised after childbirth and terminal sexual abstinence after becoming a grandmother).

However, contemporary interest in fertility largely arises from the decline in fertility in all industrialized and many other societies and the possibility of further reduction in developing countries. The latter has been assisted by family planning programmes which have now been instituted by a majority of Third-World governments (beginning with India in 1952). The determinants of fertility have been classified (by Davis and Blake 1956) as first, intercourse variables (age at first entrance to sexual union; the proportion of women never entering a union; the period spent after or between union; voluntary and involuntary abstinence, and frequency of intercourse); second, conception variables (subfecundity or infecundity; contraception, and sterilization), and third, gestation variables (spontaneous or induced abortion). The list does not separately identify the duration of breast-feeding, which was undoubtedly in most traditional societies the major determinant of marital fertility, or sexual activity outside stable unions. Bongaarts (1982) has demonstrated that only four factors—the proportion of the female reproductive period spent in a sexual union (in many societies the period of marriage), the duration of postpartum infecundability (that is, the period without menstruation or ovulation plus any period beyond this of postpartum sexual abstinence), the practice of contraception and its effectiveness, and the extent of induced abortion—provide 96 per cent of the explanation of the variance in fertility levels in nearly all societies.

Beginning in France in the late eighteenth century, and becoming more general in industrialized countries from the late nineteenth century, fertility has fallen in economically developed countries so that most appear likely to attain zero population growth. This has been achieved largely through the deliberate control of marital fertility, in most countries by contraception (before the 1960s by chemical or mechanical means as well as rhythm, abstinence, and withdrawal or coitus interruptus and subsequently

increasingly by the use of the Pill, intra-uterine devices and sterilization), supplemented by different levels of abortion. By 1993 fertility was clearly low or declining in every major world region except sub-Saharan Africa (where birth rates had begun to fall in South Africa, Botswana, Zimbabwe and Kenya—too few countries to affect the regional rate). Fertility also remained high and constant in parts of the Middle East and South-west Asia. Increasingly the relationship between the sexual act and conception has been weakened, and this has allowed a weakening in the relation between sexual activity and marriage.

feud

In pre-industrial societies, there tend to be three levels of homicide. At the most intimate level, killing within the family or local descent group is felt to bring the threat of permanent mystical misfortune, because it violates the most fundamental bonds of kinship. At the most remote level, like warfare, it lies outside the boundaries of society and social order, in an amoral cosmos beyond. Between these two levels, any homicide tends to mobilize groups that work towards some resolution. *Feud* may be said to exist where the principle of blood-debt between groups is the expected response to homicide. It tends to be associated with societies in which local agnatic descent forms the basis of corporate grouping. Ideally, a feud is strictly limited by the convention that hostilities

should be discriminating and that ultimately there should be a negotiated settlement with compensation. Those that are not directly involved in the feuding have an interest in ensuring that the conventions are upheld, or society itself is threatened. In practice, a satisfactory settlement may be evasive and the state of feud may persist indefinitely as the tally of injury mounts on both sides and resistance to any negotiated compromise increases.

It is revealing to compare feud with marriage alliance. Both are middle-range institutions, incompatible with close blood-ties, where the possibility of fratricide or incest evokes horror. Feud goes beyond the immediate relationship between killer and killed, just as marriage alliance goes beyond the union of husband and wife. The asymmetry of both may lead to further incidents of the same kind: retaliatory killings and exchange marriages. In other respects, they are neatly inverted. A marriage is initiated in the same manner as a feud may be terminated through a negotiated agreement which is confirmed by the payment of compensation (bride-wealth and blood-wealth). A feud is initiated in the same manner as a marriage may be terminated: through precipitate action between the principals (homicide and divorce). Permanence of the relationship is an ideal in marriage and a threat in feud, and vice versa. It is this structural transformation between them that accounts for their frequent association. It is the complementarity between one institution that fosters the reproduction of kin groups and of the wider society, and another that poses a threat to this reproduction. This has been summarized by Black-Michaud (1975): 'They are two aspects of precisely the same process. The ambiguities inherent in marital alliance often cause feuds, just as feuds are also frequently the "cause" of the marriages contracted to "conclude" hostilities.' In practice, any marriage to perpetuate the dead man's line is as likely to perpetuate the feud as to resolve it. In such circumstances, it is the blood-debt that has the binding force of a contract, and any settlement emerges as little more than a truce.

feudalism

There is no agreement on a definition of feudalism. The word can be used in very general terms to describe the totality of the economic and political relationships of medieval European society and of similar societies elsewhere. If such a view is taken, stress is

normally laid upon the exploitation of the peasantry by the exaction of labour services in a closed, or natural, economy. The institution of the manor is of great importance; the main social relationships are seen in terms of lordship exercised over both people and land. Frequently such a definition becomes so wide as to be little more than synonymous with medieval, and so loses any real value, but even when used more carefully, there are still considerable problems.

During the medieval period, the economy underwent such transformations as to make the application of a single model of feudalism very dangerous. Money was far more important than was once thought, and production for the market more widespread. There were wide variations, both chronological and geographical, in the degree of the subjection of the peasantry. In England many labour services were commuted in the twelfth century, when feudalism could be thought to have been at its apogee, only to be reimposed in the thirteenth century At best, society was only partly feudal, and it is significant that in his definition of feudalism one of its greatest historians, Marc Bloch (1961 [1939–40]), allowed for 'the survival of other forms of authority, family and state', alongside the structures of feudal lordship. Attempts at redefinition of the broad concept of feudalism, seeing small-scale peasant production under the political constraints of aristocratic lordship as the key element, have not proved satisfactory.

The alternative tradition to that which seeks a general model of feudalism is one which centres upon a specific type of landholding in return for military service. The word feudalism is derived from the Latin *feudum* (fief), the land held by a knight in return for service usually performed on horseback for forty days. It is possible to provide a much more satisfactory description and explanation for feudalism in such terms. The system had its origins in the collapse of public authority in the ninth century as the Carolingian Empire declined. Men commended themselves to lords, who granted them lands as fiefs. The knight and the castle were central to this feudalism, in which lordship resulted from the man, or vassal, performing a specific ceremony known as homage to his lord. The system evolved gradually, save in countries such as England and southern Italy, where it was imported by the Normans in the eleventh century. Fiefs came to be held in primogeniture, and the rights of the lord to certain dues, or feudal incidents, were given increasing definition. A lord could, for example, demand aid from his vassals to help pay for the knighting of his eldest son, and payment was expected when the son of a vassal succeeded his father in his estates. A complex legal system developed: the jurisdictional rights of lords over their tenants were an important element in a feudal society.

Such a definition is largely satisfactory, provided that it is understood that no society was ever wholly feudalized. In the case of England, the king was never solely dependent upon his feudal cavalry, but relied extensively upon mercenaries and infantry levies. The last effective feudal summons was issued in 1327, but in the first half of the thirteenth century the levels of service had been radically reduced, so that the quotas of knights came to bear little relationship to the feudal landholding structure. Castles were initially an integral part of the feudal organization of the country, but when Edward I came to build his great castles in Wales in the late thirteenth century, he used paid workmen and employed paid troops as garrisons. Such castles can hardly be described as feudal. The system of hiring soldiers by means of contracts and the issue of livery in the later Middle Ages has been described as 'bastard feudalism', but the true feudal elements of landed

fiefs, heritability and homage were all absent. Yet the legal aspects of feudalism in England long outlasted the military utility of the system; there was even a revival of feudal techniques of money-raising in the early seventeenth century.

If it is only with care that the term feudalism in a strict sense can be applied to a western European country in the Middle Ages, then it is only with great difficulty that it can be used with reference to different regions and periods. Medieval Byzantium and Islam, with the *pronoia* and *iqta* respectively, had types of land grants which were not entirely dissimilar to fiefs. The *iqta* could only exceptionally be passed on by a holder to his children, but by the twelfth century the Byzantine system was moving towards the heritability which characterized western feudalism. The legal structure of European feudalism was largely lacking in these parallel systems. Japan is frequently cited as developing something very akin to the military feudalism of western Europe, but an economy based on rice production, and a wholly different cultural and legal tradition, made for contrasts as well as similarities. For those who are influenced by Marxist theories, however, feudalism represents a stage through which most societies must pass in the course of their development. Such a view involves using an extremely general definition of feudalism, with its attendant difficulties.

Many of the arguments of scholars over feudalism have been the result of a failure to agree upon definitions. No one word, no single model, can ever sum up the complex and varying structures of medieval societies. As a term describing a very specific set of relationships within the noble and knightly classes of medieval Europe, feudalism is convenient, but the word should only be used with great circumspection.

financial crisis

A financial crisis is defined as a sharp, brief, ultra-cyclical deterioration of almost all financial indicators—short-term interest rates, asset (stock, real estate, land) prices, commercial insolvencies and failure of financial institutions (Goldsmith 1982).

The process of a financial crisis is often described (e.g. Kindleberger 1989; Minsky 1986) as a succession of several phases: a displacement (exogenous shock), a speculative mania (with euphoria, overtrading and excessive gearing), financial distress, and, finally, catastrophe.

First is an exogenous shock to the economic system, some unexpected change that alters profit opportunities and induces changes in investment. It may be outbreak of war, the end of a war, or political revolution. It may be more narrowly economic, such as discovery of a new resource, a major innovation, good crops or bad crops. It can be narrowly financial—the unexpected success of a security issue, conversion of debt to lower interest rates, leading holders to try to maintain their returns in new investments. Whatever the event that perturbs the system, it alters investment opportunities and leads usually to speculation for capital gains.

If the change is sufficiently pervasive, euphoria and overtrading are likely to follow. The objects traded depend on the nature of the shock, and may consist of many things: commodities, stocks, bonds (foreign or domestic), railways, factories, mines, office buildings, houses, land, virtually anything substantial in value. Rising prices lead to further price increases, called 'bubbles'. Success of early investors induces others to participate. As more funds are borrowed, credit becomes distended, interest rates rise, and some marginal buyers may be forced to liquidate. Some, who anticipate that prices of assets almost reached their peak, cash in their gains. Prices stop rising, may level off or may start to slip. There follows a period called 'financial distress', as the confident expectation that prices will continue to climb gives way to doubt. If expectations of a price rise are replaced by expectations of a fall, a financial crisis is likely. A rush from real or financial assets into money drives down the prices of those assets and in acute cases leads to bankruptcy of individuals or concerns still holding them with borrowed funds, and even to bank failures.

Examples of financial crises abound in modern economic history. Among well-known earlier cases are the tulip mania in The Netherlands (1637) and the South Sea Bubble in Britain (1719). During the nineteenth century, the British economy experienced business cycles that recurred approximately every ten years. The great depression that started with the stock market crash in 1929 affected most of the world. (Similarly, 'Black Monday' in October 1987 created a fear for financial instability.)

Examples of significant excessive lending have been loans by international syndicates of banks, notably to Mexico, Brazil and Argentina. This was initiated by easy money in the USA beginning in 1970, and accelerated by rises in oil prices in 1973 and 1979 that increased not only the surplus of oil producing countries as supplier of funds, but also the

need for loans by non-oil producing countries as well as the capacity to borrow from oil producing developing economies. Suddenly, interest rates in the US market jumped upward. Accordingly, governments of borrowing countries became insolvent, or at least they claimed to be so.

In the USA, when inflation pushed market interest rates above Regulation Q, the maximum ceilings on the deposit interest rates in the 1970s, the Savings and Loans Associations (S&Ls) suddenly lost saving customers. Deregulation of interest rates was implemented to help S&Ls, but it backfired. S&Ls that were protected by the Federal Deposit Insurance Corporation (FDIC) engaged in risky investments, and more than a thousand of S&Ls went into financial trouble. Eventually they were to be rescued by tax money that was estimated to be in excess of US $80 billion in 1992.

Oriental countries share the incidence of financial crises. For example, a boom in the Japanese economy during the First World War was interrupted by a severe stock market crash in 1920 and a devastating earthquake in 1923. To reduce the unfavourable impact to the credit system, the Bank of Japan extended loans as a lender of last resort and most likely weakened the discipline of the banking sector. The loans extended after the earthquake was not recovered, and triggered bank-runs when the finance minister mis-announced a bank failure in the Diet. These bank-runs and credit collapse are now known as the 'financial crisis' of 1927. After this incident, banking regulation was substantially tightened in Japan.

Incidentally, the relative intensity of disturbances to the financial sector at present, namely in the early 1990s in Japan, is at least comparable to that of the financial crisis of 1927. The current distress stems most likely from the overly expansionary monetary policy of the Bank of Japan during 1987 to 1989 undertaken with the excuse of defending the dollar by policy co-ordination, and the sudden monetary contraction that immediately followed (Hamada, 1995).

Whether financial distress ends in a financial crisis depends on a variety of factors, including the fragility of the earlier extensions of credit, the speed of the reversal of expectations, the disturbance to confidence produced by some financial accident (such as a spectacular failure or revelation of swindles), the regulation of banking industry, and the degree of the financial community's confidence in the central bank's role as a lender of last resort.

Expectations are important. Conventional views (e.g. Kindleberger 1989; Minsky 1986) recognize explicitly the role of irrational expectations and group psychology in critical stages of a financial crisis. People are often motivated by fear, rumour, and panic psychology in critical situations, and accordingly behave differently from what rational expectations economists usually postulate.

Economics of asymmetric information provides models that generate bank runs and financial panic even under the assumption of rational expectations by agents. For example, Diamond and Dybvig (1983) characterize a bank-run situation where the very expectations by the public that bank reserves may drain do indeed realize bank-runs even if there is no fundamental weakness in the business of the bank. In other words, the wrong co-ordination of expectations among people leads the society into a trap of choosing the worst equilibrium among multiple self-fulfilling equilibria.

Whether a financial crisis becomes serious or ephemeral depends to a considerable

extent on how it is handled by monetary authorities. One doctrine is that the central bank supports a market in a case of crisis as a 'lender of last resort', a concept fully rationalized in Walter Bagehot's *Lombard Street* (1873).

There is, however, an incentive problem in using a lender of last resort: the more a financial market knows it will be helped in emergency, the more likely it is to take the chances that will land it in one. This is the 'moral hazard' principle in insurance, that the more insurance one has, the less motivated one is to be careful. It is on this ground that monetary authorities usually leave some doubt as to whether they will rescue markets and banks in difficulty.

A financial crisis may be shared in several countries. Propagation of the boom takes place through the rise of internationally traded commodities or securities, through capital flows which increase the recipient's monetary base and induce credit expansion, or through the mere communication of euphoria.

In the world depression of 1929, the crisis started in Germany and smaller European countries when the USA, in its fascination in 1928 with the rising New York stock market, cut off long-term lending to those areas. The stock market crash in 1929 itself was precipitated by short-term capital withdrawals from London in response to the Hatry crisis of September 1929 (Kindleberger 1986).

An international financial crisis requires an international lender of last resort. In the nineteenth century the City of London played such a role, occasionally helped by other central banks when London itself faced a crisis. In the 1929 depression, Britain, financially weakened by the First World War, ceased to act as the international lender of last resort, and the USA (and France) were unwilling to take on the role on an adequate scale.

The USA undertook to stabilize the world economy from the Second World War to about 1971. When the debt crisis reached the stage of distress in 1981 and 1982, the world turned not to the USA but to the International Monetary Fund (IMF). The IMF successfully organized rescue operations from Mexico, Argentina and Brazil on a temporary basis by using its own resources, those of the Bank for International Settlements, and advances from the US Federal Reserve System, and by persuading commercial banks not to halt lending, but in fact to lend more.

financial system

Financial systems provide society with a mechanism for facilitating trade, a machinery for transferring resources from savers to investors, and a means of holding wealth in a convenient form. Their origin lies in the need for a satisfactory payments system; further development has had more to do with the requirements of savers and investors, of wealth-owners and those who control the use of physical capital assets.

It is these physical assets—lands, buildings, equipment and other assets comprising the physical capital stock—which form the foundation on which the superstructure of the financial system is created. Financial instruments are claims whose value depends ultimately on physical resources (including human capital) or the income derived from them. The institutions within the financial system attempt to divide up or combine these ultimate claims in ways which match their clients' needs. The result in a sophisticated system is a great variety of instruments, handled by a broad and diverse range of institutions and financial markets.

The provision of notes and coins as generally acceptable means of payments has usually been regarded as a duty (or profitable right) of the state—the sovereign, government or central bank. These suffice only for small payments and are nowadays supplemented in even the most rudimentary financial system by banks, which take deposits and make payments by effecting transfers between accounts. Allied to this function is the provision of finance for trade—short term loans to bridge the gap between the dispatch of goods and the receipt of payment for them. Though important, activities associated with trade and payments now tend to comprise only a small part of the activities of financial systems.

Much more significant are activities associated with saving, investment and the ownership of wealth. The financial system enables society to separate the ownership of wealth from the control of physical capital and to ensure that savers and wealth-holders have access to financial assets whose characteristics are attractive to them and differ from those of the physical assets which underpin their value. For example, savers frequently seek safety and liquidity in the asset: they hold, whereas physical assets are durable, liable to lose their value, and difficult to turn into cash quickly; the scale of investment is often of an order which dwarfs the amount available from individual savers.

Financial systems thus facilitate effective capital accumulation. By *intermediating* between savers and investors, financial institutions enable surplus resources to be transferred to those who are able to use them. By *mobilizing* saving from many savers, they provide finance for large-scale investment projects. By *transforming* securities, the system allows the risk inherent in productive activity to be concentrated on wealth-holders who are prepared to take it, while others obtain the safe and liquid assets that they want. In a properly functioning system these activities can be expected both to increase the saving which is available for investment, and to raise the productivity of the investment that takes place.

Most financial systems consist largely of *intermediaries*—institutions which issue their own liabilities, and hold as assets the liabilities of ultimate borrowers or of other intermediaries. They fall into three broad groups: banks and other deposit-taking institutions, such as building societies, savings and loan associations, or credit unions; long-term investing institutions, such as life assurance companies, pension funds and investment companies or trusts; and special credit institutions, usually set up by governments to provide long-term finance for particular purposes. These institutions often compete with each other in the market for savings, loans, or both. In addition, most sophisticated financial systems, and some that are not yet highly developed, contain organized markets. These are security markets, such as the Stock Exchange, where long-term securities are issued and traded, and money markets, where short-term deposits and loans are made.

Economic and political conditions are the principal factors governing the evolution of financial systems. Goldsmith (1969) has suggested that three broad categories of systems can be identified, distinguished according to the scale and composition of the economy's financial superstructure. First, in the systems found in Europe and North America up to the mid-nineteenth century, the total value of financial instruments was low, financial institutions accounted for a low share of the outstanding assets, and commercial banks were pre-eminent. Risk-capital was predominantly in the hands of the owners of (comparatively small-scale) enterprises, and did not play a large part in the financial system. The second structure is similar to the first one, and was found in non-industrialized countries in the first half of the twentieth century. But in this case governments and government-supported institutions played a larger part, thanks to the mixed nature of the economies. A similar situation can be found in many developing countries, with government-supported institutions supplying capital for particular purposes. The third category, common among industrial countries in the twentieth century, shows a considerably greater degree of financial development, a higher proportion of risk-assets, and increased diversity among financial institutions. Some (e.g. The Netherlands, UK and USA) have strong long-term institutions supplying risk-capital; others (e.g. France and Italy) rely more heavily on special credit institutions. Socialist countries might be thought to form a fourth category: their financial systems are generally less highly developed than in market economies, with banks dominant among financial institutions.

While the tendency for financial and economic development to proceed in tandem is well documented, the direction of causation is still the subject of controversy. Some argue that financial development is a response to economic growth, others (e.g. Drake

1980), that improved financial facilities act as an independent stimulus. There is probably some truth in both views: financial innovation, in the form of new instruments or institutions, often results from changes in the economy; but, once created, new facilities are made available to others and help to stimulate further growth. Thus, even if financial development seldom sparks off economic growth, there is a positive feedback from the financial to the economic system.

firm, theory of

The role of specialization in economic progress was emphasized by Adam Smith. Now specialized activities need to be co-ordinated, either by conscious integration within an organization or through market relationships; the effects of both organizational forms and market structures on economic performance are topics which date back at least to Smith. But few economists have tried to treat the firm simultaneously as an organization and as a component of an industry or market. Marshall (1919; 1920) was one of the few, and business enterprise was at the core of his theory of economic development. The problems of the firm were problems of acquiring, generating and using knowledge: knowledge of production methods, existing and potential markets, and of the ways to construct an organization and to motivate its members to create opportunities for profit. The firm's customers, suppliers and competitors, including potential competitors, at once constrained its actions and provided opportunities to those who had the wit to perceive and the ability to exploit them; those opportunities were enhanced by the development of trade connections. For the analysis of this complex evolutionary process the methods of static equilibrium offered some useful guidance, but could be misleading if rigorously pressed; there was no substitute for the detailed investigation of particular organizational and market arrangements, in relation to the technical conditions and demand characteristics of each case.

   Marshall's successors ignored his advice, and the study of the firm disintegrated. The major activities of firms were defined away by the assumption of fully specified demand and cost functions, and the firm itself became a fictitious person whose actions were completely determined by its situation. The 'theory of the firm' was the label given to a set of exercises in constrained optimization, by which equilibrium price and output were

derived for a series of market structures—perfect and imperfect competition, oligopoly and monopoly—and the effects of change read off from shifts in demand or cost curves. Cournot's analysis was reinvented. Robinson's *Economics of Imperfect Competition* (1933) epitomized the triumph of the formal model, and with it the dominance of problems generated within the theoretical structure, for the origins of imperfect competition theory lay in the logical impossibility of reconciling increasing returns (statically defined) with perfectly competitive equilibrium. Both were concepts which Marshall had avoided.

Chamberlin's (1933) conception of monopolistic competition was substantially different. Whereas Marshall had insisted that elements of competition and monopoly were usually blended in practice, Chamberlin set out to blend them in theory, and tried to incorporate both product variation and selling costs within a formal analysis which used the method (though often not the language) of static equilibrium. Despite his limited success, he provided the primary inspiration for the strong American tradition in industrial economics, though some of its practitioners borrowed their welfare criteria from Robinson. Chamberlin's approach was also distinguished by his attention to oligopoly, which steadily increased over the years. His insistence that oligopolistic behaviour (like all behaviour) depends on expectations, and that there could be no general theory of oligopoly because there could be no general theory of expectations, has haunted theorists ever since.

There are many specific models of oligopoly, though it is noteworthy that most restrict themselves either to relationships within the group (as, for example, the dominant firm and kinked demand models) or to the barriers, natural or artificial, against new entrants, and do not attempt to deal with both issues together—an example of economists aversion to multi-level analysis. Andrews (1949) exceptionally tried to develop a non-formal theory of competitive oligopoly, in which the threat of cross-entry and the desire of managers to show themselves worthy of promotion might combine to ensure good value for the customer's money—especially if the customer was another firm—but neither his methods nor his conclusions were acceptable. However, the situational determinism which is apparently so effective in producing general solutions for other market structures will not deliver equivalent results for oligopoly, and the application of game theory, still heavily dependent on Cournot for its equilibrium concepts, has multiplied the possibilities, without so far encouraging economists to study business practice in order to improve their predictive ability and their understanding.

This failure provided a theoretical opportunity for Baumol (1959): instead of examining a standard firm in different market structures, he proposed to deduce the effects of different managerial objectives in oligopoly. He assumed that a firm's decision makers sought to maximize, not profit, but sales revenue; his lead was followed by Williamson (1963), who proposed a managerial utility function, and Marris (1964), who favoured growth. In all three models, the decision makers were constrained not only by market opportunities but also by their shareholders: in the first two by the need to provide an acceptable profit, and in the third by the risk of takeover. Each model generated some plausible contrasts to the results of profit maximization; yet, despite assuming oligopoly, none attempted to deal seriously with interdependence, and, though invoking organizational factors to justify their choice of managerially oriented objectives, none

offered any analysis of organizational influences on behaviour. The firm remained a fictitious person.

In 1937 Coase had argued that firms came into existence when formal organization could undercut the costs of market transactions, but his implicit invitation to examine how and when this might be possible has elicited a tardy and sparse response, which has been dominated by Williamson (1975; 1985; 1986). Most economists (e.g. Alchian and Demsetz 19[7]2; Fama 1980; Jensen and Meckling 1976) have preferred to extend market analysis into the firm, especially through the use of agency and game theory, which give scant attention to the fundamental uncertainties of technology and markets. In a comprehensive and detailed exposition Milgrom and Roberts (1992) focus on the efficient outcomes of free bargaining, effectively implemented and enforced through incentive compatibility. Though Williamson also argues that governance structures are chosen for their efficiency, he believes that bounded rationality often precludes the *ex-ante* assurance of incentive compatibility, and insists that firms make extensive use of hierarchical fiat.

Yet even Williamson has given rather little attention to the actual problems and processes of decision making, which are the focus of what is usually called (in economics) behavioural theory. This kind of theory is characterized by its emphasis on the inadequacy of knowledge, and on the limited ability of people to make use even of what knowledge they think they have. Simon's (1976) proposal to substitute procedural for substantive rationality makes obvious sense at a time of much concern over control systems, information systems, techniques of planning, and the machinery of government. To Simon's (1978) problem of how to decide what to do should be added the prior question of how to decide what to think about—a question which might also be addressed to economists analysing the firm. Cyert and March's (1963) study of short-term decision making has not been widely followed up, but Nelson and Winter (1982) have shown how the approach may be adapted and applied to technical change.

The firm as an agent of discovery and progress is once more receiving attention. It was a key element in Schumpeter's (1943) theory of economic development through 'creative destruction', but Schumpeter is not usually thought of as a theorist of the firm. There has been some interest in the concept of the entrepreneur as the agent of change; although neo-Austrians have so far studied the entrepreneur only as an individual in the market, Casson (1982) depicts the entrepreneur as the creator of an organization, facing some of the problems discussed by Marshall. Meanwhile, studies of innovation and technical change have increasingly recognized the need to investigate how organizational form as well as market structure influences the generation, transmission and exploitation of knowledge, and also the effects of these processes on markets and organizations. For this purpose there is no better definition of a firm than Penrose's (1959) 'pool of resources the utilisation of which is organised in an administrative framework' and no better application of that definition than the historical studies of Chandler (1962; 1977; 1990). The capabilities of a firm reside in its institutions as well as its skills. But these institutions embody the unintended consequences of rational choice: co-ordination, in firms as well as markets, reflects spontaneous order as well as conscious design. Indeed, we may be returning to Marshall's conception of a population of specialized firms generating variety within an evolutionary process. If so, we should remember Marshall's

recognition of inter-firm linkages—a theme explored by Richardson (1972)—and the importance of markets as a pool of resources offering variety (Langlois 1992). Firms and markets would then feature as complementary and competitive institutions which both shape and are shaped by the course of evolution.

first language acquisition

When infants acquire a first language, they learn one of the most complex skills of their lives and they attain adult levels of skill in many domains by the age of 5 or 6. How do they learn a system that requires mastery of the sound system, a huge vocabulary, grammatical rules, meanings, and rules for usage, as well as articulatory skill, auditory discrimination, memory storage, recognition, and retrieval? What may be innate and what learned in this complex task has long intrigued psychologists, linguists and philosophers (Bloom 1993). In their efforts to answer this question, researchers have kept records of how children advance from babbling, to words, to complex utterances. Since the 1960s, they have paid increased attention to the acquisition of different languages (Slobin 1985; 1991) and to the stages children go through.

Children hear language all around them. Adults display for them the syntactic structures and also demonstrate how words partition conceptual spaces (Slobin 1985; 1991). Adults offer essential information about the conventions of the language being acquired, and often direct children's attention by repeating, rewording, and re-casting child utterances into conventional forms.

When children start to produce words (anywhere from 12 to 18 months), they usually use just one at a time. But soon they begin to combine two or more, moving from utterances like *Raisin* to *More raisin* to *Me want raisin* (Brown 1973). Their early nouns pick out objects, often in such roles as agent, patient, or location. They mark what is 'given' and what 'new' in the conversation, and also grammatical relations like Subject-of and Direct-Object-of.

To do this, children need to learn how to modulate the meanings of nouns and verbs. In English, they can add a plural *-s* ending to nouns, for example, and mark limited duration *(-ing)* or past *(-ed),* on verbs. In more highly inflected languages, they may learn case and gender endings for nouns and adjectives, and verb endings to mark tense, aspect, person and number. Such inflections show which pieces of an utterance belong together and, for instance, which noun agrees with the verb. To learn inflections, children must identify stems and endings in words, and the meanings of each, together with any variants in form. For example, the plural of *cat* in English is pronounced [kats] (with an 's') while the plural of *dog* is [dogz] (with a 'z'). Learning variants takes time. In addition, some

common words are irregular. Compare regular *cat/cats* or *dog/dogs* with *mouse/mice, child/children* or *sheep/sheep;* or regular *jump/jumped* or *look/looked* with *go/went, sit/sat* or *bring/brought.* Children are pattern makers; they regularize irregulars to produce plurals like *foots* and *mans,* and past tense verbs like *comed, buyed* and *hitted,* before learning the irregular forms (Bloom 1993; Brown 1973; Clark 1993).

Most children produce word combinations and inflections by age 2–2 1/2. In the next few months, they elaborate their utterances: they add demonstratives, articles and quantifiers *(that, the, some);* adjectives *(stuck, wet);* auxiliary and modal verbs *(do, be, can, will).* They add adverbs and prepositional phrases *(there, in the cupboard; loudly, in a hurry);* adverbial clauses *(They were tired WHEN THEY GOT HOME);* relative clauses *(the boy WHO WAS WATCHING THEM);* and complements *(They wanted TO RUNAWAY, She said THAT SHE WAS COMING)* (Bloom 1993). But acquiring syntax takes time. Many early elaborations omit the appropriate conjunctions *(before, while)* and complementizers *(that, to),* or contain the wrong one for the meaning intended.

Acquisition of vocabulary is a major ingredient in language. Children learn words very rapidly, moving from a vocabulary of 100–400 words at age 2 to around 14,000 by age 6. By the time they are adults, they may have up to 50,000 at their disposal. During acquisition, children identify word-forms and map meanings on to them (Bloom 1993; Clark 1993). They analyse complex words into their component parts *(pram-pusher>pram+push+er; blackness>black+ ness),* and use these, when needed, to coin words with new meanings (*to scale* for adult 'weigh', *sander* for one who grinds pepper, or *far-see-er* for 'telescope'). Such coinages emerge from about age 2 onwards to fill gaps in the child's current vocabulary (Clark 1993).

Words work only if they are recognized, and children try hard to produce recognizable forms. While their earliest words may bear little resemblance to adult forms ([ga] for *squirrel*), by age 3, much of what children say is readily understood. But to get words right, children need to listen and store what they hear, hone their articulatory skills and identify the relevant sounds in each word attempted. When they produce words, they must match adult versions (stored in memory), moving closer with practice, for example, from simple consonant-vowel combinations (e.g. [do] for *dog*), to adding final consonants (e.g. [dog]), and mastering consonant clusters (e.g. from [kai] to [krai], for *cry*) (Ferguson *et al.* 1992).

Learning the structure of a language is only one side of acquisition. Children must also learn how to *use* language appropriately. They need to know how to make requests and what counts as polite (Andersen 1990). By age 4, many children distinguish among *Give me some cake, Can I have some cake?, Could I have some cake please?,* and *That cake looks very good, doesn't it?* As their knowledge of form and meaning expands, they also try out other language skills such as story-telling (Berman and Slobin 1994).

Finally, children seem to learn two languages just as easily as one (McLaughlin 1984). But the point at which they start on the second makes a difference. The earlier they start, the more acquisition of the second looks like acquisition of the first. How well a second language is learned also depends on the social value it carries in the community.

folklore and myth

The discipline of folklore was given its name by William Thoms only in 1846, but its origins go back to the beginning of the nineteenth century. It was a product of an intellectual movement opposed to the philosophy of the Enlightenment and associated with pre-Romanticism and, especially in Germany, with *Sturm und Drang.*

The publication in 1760 of James MacPherson's *Fragments of Ancient Poetry Collected in the Highlands of Scotland and Translated from the Gaelic or Erse Language* caused shock-waves throughout Europe. The Celtic bard Ossian was regarded as a Nordic Homer. The modern sensibility welcomed a poetry which, while ignorant of formal rules, was original, authentic and bursting with energy. The success of Ossian's poems was both profound and enduring, although it was gradually established that they were the work of MacPherson himself.

J.G.Herder, the spokesman for *Sturm und Drang* in Germany, provided the conceptual basis for the academic study of folklore. Popular poetry was an emanation of the popular spirit. Various cultures, which were 'equal in necessity, equal in originality, equal in value, equal in happiness' functioned in an organic manner.

The next generation developed these ideas. For the brothers Grimm, there was no question but that popular cultural products, stories, legends, *lieder,* beliefs and customary law shared the same source as mythology itself. They were various forms, perhaps modified in the course of history, of natural poetry *(Naturpoesie).* This poetry was born and evolved in an organic unconscious fashion in the human spirit. Its creation and functioning were controlled by the same mechanisms as those which ordained living organisms or natural phenomena, or, more to the point, human language. This ancient

poetry was the product not of invention but of divine revelation. In time it generated a variety of epics, legends and stories. While it may sometimes be convenient to distinguish these genres of popular literature, they may equally legitimately be merged with each other since their content is the same—they all participate in the nature of myths. In the preface to the 1819 edition of *Kinderund Hausmärchen,* the Grimms suggested that the ancient German myths could be recognized in the surviving folktales. In the postscript to the 1857 edition, Wilhelm Grimm expressed the same idea with greater precision. The stories were survivals, (the debris), of ancient beliefs which are figuratively expressed in them, and which are to be identified, however fictionalized, in the motifs of a performance. The mythical content fragments, because the story is a living organism. Continually evolving, it sheds beliefs which are no longer comprehensible, and integrates new elements. However, the further back one goes in time, the more the mythical element *(das Mythische)* predominates, until it constitutes the essence or sole foundation. This mythical context, which is retained in a fragmentary form in the stories, satisfies our taste for the extraordinary, the marvellous. It accounts for a certain category of stories (nos 300–749 in Aarne-Thompson's typology) in which mythical features are presented in a figurative fashion, in and through the narrative.

This conception of the nature of the popular story and of folklore more generally was accepted by scholars in the nineteenth and early twentieth centuries. Stories developed out of ancient myths and tended to erode as, with the passage of time, they were distanced from their ancient source in natural poetry. The scholars of the nineteenth century regarded folklore as a product of the degeneration of myths, which eroded and degenerated over the centuries. One had to trace them back in order to discover their pure and noble structure.

The concern of scholars was consequently with the mode of degeneration (or 'devolution', to use the expression of Dundes 1975) from myth to folklore. The English school, represented by Tylor (1871) and Lang (1884; 1887), developed the idea of 'survivals' in an evolutionist perspective. Survivals were the remains of dead civilizations which persisted in a living culture in the form of beliefs, practices, rituals or tales. The idea was accepted in France, where Sébillot (1908) wrote of 'contemporary paganism' and Saintyves (1923) congratulated the anthropologists for providing scholars with 'the historico-scientific notion of survivals', permitting them to recognize in popular stories commentaries on rituals which had fallen into disuse. As late as 1928, V.Propp took the view that rites, myths, the forms of primitive thought, and certain social institutions were anterior to particular stories and provided the means for their interpretation.

Modern scholars have abandoned this 'archaic illusion', which is ideological in nature, but without investigating its rationale or its origin. In consequence, they have instituted a radical distinction between myth and folklore, limiting themselves to the collection of items of folklore or to the study of their social function, and applying both to myths and to popular stories formalist methods which pass over questions of content. Yet it is surely the case that folkloric products may have a mythic content, even though this may be masked by superficial and formal features. This presence of the 'mythic' is not the consequence of what Lévi-Strauss (1952) called 'historical viscosity'. Folklore retains its functions, especially the permanent necessity of transmitting myth, by whatever means.

Fordism

Fordism is generally understood as a post-war affair, often synonymous with the long post-war boom from the 1950s to the early 1970s, and centred largely on the US and European economies. Antonio Gramsci is attributed with the first use of the term to convey something distinctive about the cultural values emanating from the American way of life in the 1930s (1971); indeed, it is the broad vision of Fordism as more than just an economic phenomenon which has tended to hold sway. For many, Fordism symbolizes the arrival of a new type of mass worker, a different kind of mass lifestyle, and the onset of an interventionist, welfare state. Put another way, Fordism acts as a metaphor for *modern* capitalism. The looseness of the term has been reduced, however, by Saver's (1989) specification of four different senses of Fordism.

The first sense of Fordism takes its cue from the mass production systems pioneered by Henry Ford and his engineers at the Detroit car factory in 1913/14. Fordism essentially refers to a *labour process* based upon assembly-line techniques, specialized machinery, a fragmentation of tasks, and control by management over the line. The influence of Frederick Taylor's form of scientific management is to be found in the standardization of work tasks and the more detailed division of labour, as well as in the use of semi-skilled labour. Where Fordism differs from *Taylarism,* however, is in the use of technology to impose a work discipline upon the labour force, rather than rely upon the reorganization

of work.

The second sense of Fordism goes beyond the labour process to include the *economic role* of the mass production industries within an economy as a whole. In relation to their size, Fordist industries are seen to have a disproportionate effect on economic growth through their ability to generate and transmit growth to other sectors, many of which will include small-scale producers. Growth in the car industry, for example, creates a demand for a whole range of inputs, from electrical components to glass fittings and plastic accessories. Such industries may grow by meeting the demands of the mass producers. Equally, the mass producers may generate disproportionate amounts of growth through the economies that arise from their scale of production. Although Fordist plants have high fixed costs, once in place they can realize increasing returns to scale as output rises. They are thus able to exert a dominant role in an economy.

A third meaning attached to Fordism refers to its *hegemonic role* in an economy. This again refers to the disproportionate role of the mass production industries, although in this instance it refers to the influence of the Fordist model outside of the mass production sector. So, for example, the extent to which collective bargaining agreements, rate-for-the-job contracts, or the imposition of managerial hierarchies occurs among small batch producers or even in the public services sector would be regarded as an indication of how widespread the Fordist model had become.

A fourth sense of Fordism comes closest to the notion of Fordism as an industrial era. It refers to Fordism as a *mode of regulation* aimed at sustaining a particular kind of economic growth; namely one that attempts to maintain the balance between mass production and mass consumption. Institutions such as the state are seen as central to the maintenance of such a balance and, in the case of the long post-war boom, the Keynesian interventionist, welfare state is held up as an example of how a mode of regulation may hold together a particular industrial era. Michel Aglietta's account of Fordism set out in *A Theory of Capitalist Regulation: The US Experience* (1979) is perhaps the best known regulationist study of the long post-war boom and, indeed, equally well known for drawing attention to the much heralded crisis of Fordism.

The crisis of Fordism which dates from the early 1970s is said to mark the end of an industrial era and the movement towards a new era based upon more flexible forms of economic organization and production, together with more diverse patterns of consumption and lifestyles. The terms used to describe this shift are neo- or post-Fordism, depending upon which characteristics of the route out of Fordism are stressed. *Neo-Fordism* emphasizes the continuity of the labour process under Fordism, whereas *post-Fordism* stresses a break with all that is Fordism. The hallmark of both, however, is that flexibility is said to represent a solution to the rigidities of an economy organized along Fordist lines.

Such solutions are far from unanimously held, however, as indeed is the notion of Fordism itself. One weakness of the concept of Fordism, noted by post-industrialists in particular, is the inability to see beyond large-scale mass production and to take into consideration the development of the service industries in the post-war period. At root here is the assumption, disputed by post-industrialists, that manufacturing, not services, represents the 'engine of growth' within a modern economy.

forecasting

see **planning, economic; population projections; prediction and forecasting**

Foucault, Michel (1926–84)

Michel Foucault, the French philosopher, was successively a university teacher, professor at Clermont-Ferrand, Paris-Vincennes, and from 1970, professor of the history of systems of thought at the College de France.

At first sight—and on account of the tide of his chair—one might take Foucault to be engaged in a kind of history of ideas. In fact, he refuses any such definition of his work. His *L'Archéologie du savoir* (1969) (*The Archaeology of Knowledge,* 1972) is directed against the discipline called 'the history of ideas', which he takes to be something like a totalizing overview that rewrites the past in order to produce a unified object of study. In the same book he criticizes certain aspects of his own earlier work: for example, the presupposition of the existence of a 'general subject of history' contained in *Histoire de la folie à l'âge classique* (1961) (*Madness and Civilization,* 1967). In *Les Mots et les choses* (1966) (*The Order of Things,* 1970) Foucault claims that humankind is a modern invention and destined to disappear. Such an opinion might lead us to call him a structuralist, for he takes the idea of *man,* in any sense recognizable to the contemporary

reader, to be a product of nineteenth-century structures (in fact, of structures of knowledge or *savoir*). But in *L'Archéologie du savoir* he had also turned against the structuralist leanings of his earlier writings.

The problem appears to have lain in the use made in those writings of the concept of an *episteme:* roughly, a structure of knowledge or (in his own terms) a 'discursive formation', which determines the manner in which the world is experienced in a given epoch. Can a study of the history of the appearance and disappearance of epistemic formations itself make use of the concept of *episteme* as an *explanatory* tool? If not, what does explain epistemic ruptures and eruptions? Foucault insists that the explanation must lie in 'the regime of materiality', which he then interprets as consisting in the *institutions* in which the material relations structuring discursive events are embodied.

Knowledge therefore has to be explained in terms of institutions, and of the events which take place in the latter—events of a technical, economic, social and political nature. But institutions cannot function without the exercise of *power*. Foucault therefore turns to an examination of the question of power, which, being institutional, is not and cannot be personal in origin or character. Unlike Marxists, however, he wants to study not some mechanistic process whereby power in general is explained in terms of economic ownership, but rather what he calls the 'strategies' of power. In order to avoid any semblance of anthropocentrism, he explains that he means by the term 'strategy' not the conscious plan or design of some human individual or group but 'the effect of a strategic position'.

The merely descriptive—and structuralist—notion of the *episteme* is now subordinated to a genuinely historical conception of the eruption of new epistemic configurations, including new sciences, a conception which (as mentioned) is avowedly materialist.

Power, he says, is located in strategies which are operative at every level: they cannot be reduced to the power of, for example, the state or of a ruling class. Power is productive (and in particular productive of knowledge). He talks about a 'microphysics of power', power disseminated throughout the whole of society. There are of course clashes between the multifarious and multi-levelled strategies of power. What is not clear is how the outcome of such clashes and similar processes is to be explained, given that no general mechanism of the generation of power is provided. Foucault has thus been criticized for offering, at the theoretical level, no more (nor less) than a *metaphysics* of power.

This critique does not detract from the interest of the detailed studies carried out by him (often in collaboration with pupils): for instance, his study of prisons and imprisonment (*Surveiller et punir,* 1975) (*Discipline and Punish,* 1977) and of the history of sexuality (*La Volonté de savoir,* 1976) (*The History of Sexuality,* vol. I, 1979).

Foucault's metaphysics of power—if such it is—is in any case, as we have seen, a microphysics. This point is worth underlining in the light of the exploitation made of his work by the so-called 'nouveaux philosophies' (André Glucksmann and others), who have drawn on some of its themes or vocabulary in order to produce a violently anti-Marxist metaphysics of the state—otherwise called a theory of totalitarianism which reintroduces the idea, rejected by Foucault, of a single centre of power (see Glucksmann 1977).

Frankfurt School

The Frankfurt School refers to the work of members of the *Institut für Sozialforschung,* which was established in Frankfurt, Germany, in 1923 as the first Marxistoriented research centre affiliated with a major German university. Under its director, Carl Grunberg, the institute's work in the 1920s tended to be empirical, historical and oriented towards problems of the European working-class movement, although theoretical works by Karl Korsch, Georg Lukács and others were also published in its journal, *Archiv für die Geschichte des Sozialismus und der Arbeiterbewegung.*

Max Horkheimer became director of the institute in 1930, and gathered around him many talented theorists, including Erich Fromm, Herbert Marcuse and T.W.Adorno. Under Horkheimer, the institute sought to develop an interdisciplinary social theory which could serve as an instrument of social transformation. The work of this era was a synthesis of philosophy and social theory, combining sociology, psychology, cultural studies and political economy. The results appeared in its own journal, *Zeitschrift für Social forschung* (1932–41), which contains a rich collection of articles and book reviews still worth reading.

The first major institute project in the Horkheimer period was a systematic study of authority, an investigation into individuals who submitted to irrational authority in authoritarian regimes. This culminated in a two-volume work, *Studien über Autorität und Familie* (1936). Fascism was a major interest during the 1930s. Most members were both Jews and Marxist radicals and were forced to flee Germany after Hitler's ascendancy to power. The majority emigrated to the USA and the institute became affiliated with Columbia University from 1931 until 1949, when it returned to Frankfurt.

From 1936 to the present, the institute referred to its work as the 'critical theory of

society'. For many years, 'critical theory' stood as a code for the institute's Marxism and was distinguished by its attempt to found a radical interdisciplinary social theory rooted in Hegelian-Marxian dialectics, historical materialism, and the Marxian critique of political economy and theory of revolution. Members argued that Marx's concepts of the commodity, money, value, exchange and fetishism characterize not only the capitalist economy but also social relations under capitalism, where human relations and all forms of life are governed by commodity and exchange relations and values.

Horkheimer (1937) claimed in a key article 'Philosophic und Kritische Theorie' (Traditional and critical theory) that since 'the economy is the first cause of poverty, theoretical and practical criticism has to direct itself primarily at it'. Institute members were convinced that the capitalist economy was driving bourgeois society to catastrophe through its underlying cycle of production, anarchy, depressions, unemployment and wars. They believed that increasing tendencies toward bureaucratization and social rationalization were destroying the features of individuality and freedom which the capitalist system extolled as its prize creation.

Horkheimer (1937) wrote that critical theory's 'content consists of changing the concepts that thoroughly dominate the economy into their opposites: fair exchange into a deepening of social injustice; a free economy into monopolistic domination; productive labour into the strengthening of relations which inhibit production; the maintenance of society's life into the impoverishment of the people's'. The goal of critical theory is to transform these social conditions, and provide a theory of 'the historical movement of an epoch that is to come to an end'.

Critical theory produced aspects of a theory of the transformation of competitive capitalism into monopoly capitalism and fascism, and hoped to be part of a historical process through which capitalism would be replaced by socialism. Horkheimer claimed that 'The categories which have arisen under its influence criticize the present. The Marxist categories of class, exploitation, surplus value, profit, impoverishment, and collapse are moments of a conceptual whole whose meaning is to be sought, not in the reproduction of the present society, but in its transformation to a correct society.' Critical theory is thus motivated by an interest in emancipation and is a philosophy of social practice engaged in 'the struggle for the future'. Critical theory must remain loyal to the 'idea of a future society as the community of free human beings, in so far as such a society is possible, given the present technical means'.

In a series of studies carried out in the 1930s, the Institute for Social Research sketched out theories of monopoly capitalism, the new industrial state, the role of technology and giant corporations in monopoly capitalism, the cultural industries and the decline of the individual. It articulated theories which were to occupy the centre of social theory for the next several decades. Rarely, if ever, has such a talented group of interdisciplinary workers come together under the auspices of one institute. They managed to keep alive radical social theory during a difficult historical era and provided aspects of a neo-Marxian theory of the changed social reality and new historical situation in the transition from competitive capitalism to monopoly capitalism.

During the Second World War, the institute tended to split up due to pressures of the war. Adorno and Horkheimer moved to California, while Lowenthal, Marcuse, Neumann and others worked for the US government as their contribution in the fight against

fascism. Adorno and Horkheimer worked on their collective book *Dialectic of Enlightenment* (1947), which contains implicit critiques of Marxism, as well as fascism and consumer capitalism. Departing from the Marxian theory of history, they presented a philosophy of history that traced the fate of the Enlightenment from the beginning of scientific thought with the Greeks to fascist concentration camps and the cultural industries of US capitalism. They showed how western rationality served as instruments of domination and how 'Enlightenment' turned into its opposite, mystification and oppression. The book criticized enlightenment scientism and rationalism, and implicitly implicated Marxism within the 'dialectic of Enlightenment'.

After the Second World War, Adorno, Horkheimer and Pollock returned to Frankfurt to re-establish the institute in Germany, while Lowenthal, Marcuse and others remained in the USA. In Germany, Adorno, Horkheimer and their associates published a series of books and became a dominant intellectual current in Germany. At this time, the term Frankfurt School became widespread as a characterization of their version of interdisciplinary social research and of the particular social theory developed by Adorno, Horkheimer and their associates. They engaged in frequent methodological and substantive debates with other social theories, most notably 'the positivism dispute', where they criticized more empirical and quantitative approaches to social theory and defended their own more speculative and critical brand of social theory. The German group around Adorno and Horkheimer was also increasingly hostile toward orthodox Marxism and were in turn criticized by a variety of types of 'Marxism-Leninism' and 'scientific Marxists' for their alleged surrender of revolutionary and scientific Marxian perspectives.

The Frankfurt School eventually became best known for their theories of 'the totally administered society' or 'one-dimensional society', which theorized the increasing power of capitalism over all aspects of social life and the development of new forms of social control. During the 1950s, however, there were divergences between the work of the institute relocated in Frankfurt and the developing theories of Fromm, Lowenthal, Marcuse and others who did not return to Germany, which were often at odds with both the current and earlier work of Adorno and Horkheimer. Thus it is misleading to consider the work of various critical theorists during the post-war period as members of a monolithic Frankfurt School. Whereas there were both a shared sense of purpose and collective work on interdisciplinary social theory from 1930 to the early 1940s, thereafter critical theorists frequently diverge, and during the 1950s and 1960s the term the 'Frankfurt School' can really be applied only to the work of the institute in Germany.

It is thus impossible to characterize the Frankfurt School as a whole, since their work spanned several decades and involved a variety of thinkers who later engaged in sharp debates with one another. Rather one should perceive various phases of institute work. (1) the empirical-historical studies of the Grunberg era. (2) attempts in the early to mid-1930s to establish a materialist interdisciplinary social theory under Horkheimer's directorship. (3) attempts to develop a critical theory of society during the exile period from about 1937 to the early 1940s. (4) the dispersion of institute members in the 1940s and new directions sketched out by Adorno and Horkheimer. (5) the return of the institute to Germany and its work in Frankfurt during the 1950s and 1960s. (6) the development of critical theory in various ways by Fromm, Lowenthal, Marcuse and others who remained

in the USA. (7) the continuation of institute projects and development of critical theory in Germany by Jürgen Habermas, Oskar Negt, Alfred Schmidt, and others in the 1970s and 1980s. (8) contributions to critical theory by younger theorists and scholars currently active in Europe and the USA.

In surveying the field of critical theory, one observes a heterogeneity of theories, theorists and projects loosely connected by commitment to interdisciplinary social theory, and an interest in social critique and transformation, all influenced by the work of theorists like Adorno, Horkheimer, Marcuse, Habermas or others. Critical theorists tend to be critical of empirical and quantitative social theory and more sympathetic to theoretical construction, social critique and social transformation. It continues to be an active, though frequently marginal, tendency of social theory; thus the legacy of the Frankfurt School endures.

free association

The requirement for free association is often referred to as the fundamental rule of psychoanalysis. The patient in psychoanalytic treatment attempts to express in words all thoughts, feelings, wishes, sensations, images and memories without reservation, as they spontaneously occur. Originally, Sigmund Freud introduced free association to assist in the abreaction of traumatic experiences. Later it served him especially well in deciphering the language and grammar of dreams and in describing the vicissitudes of human passion, emotion and motivation. Gradually, as psychoanalysis progressed, free association became the vehicle for elucidation of unconscious conflicts and of the history

of their formation in the life of the individual.

Free association replaced hypnosis in Freud's early investigative and psychotherapeutic work in the 1890s. The approach was consonant with his general conviction about the determinism of mental life and the importance of unconscious influences. It served and continues to serve as the principal method of psychoanalysis and of psychoanalytic psychotherapy. The word 'free' in this term indicates relative freedom from *conscious* determination. Unconscious determinants, both those that seek expression and those that oppose it (resistance), can be inferred from the many varieties of sequence, content and form of the free associations. The analyst's interventions, based on a grasp of conscious and unconscious determinants, aim to expand the patient's *freedom* of association mainly through clarification and interpretation, with a concomitant development of the patient's insight. Analysts are guided by their own associations and by the requirement of maintaining a non-judgemental attitude characterized by relative personal anonymity, neutrality and abstinence.

The systematic use of the method of free association leads to the psychoanalytic process (or processes), in which *transference* and *counter-transference* occupy a central position. Free association can be seen to promote continuity in mental functioning—the continuity, for example, of thought, feeling, memory, styles of loving, and sense of self. Discontinuities in these functions and corresponding restrictions in the freedom of association are characteristic of the psychopathology which may be expected to respond favourably to psychoanalytic treatment. In a narrower sense, free association aims to make conscious what is unconscious, to revive lost experience, to expand what is condensed, to express the components of inner conflict, and to put thought and feeling, as much as possible, into words. Although not all of mental life can be put into words, emphasis on the intimate connection between language, reason, consciousness, and the capacity for decision and resolution has been an explicit feature of the psychoanalytic method from the beginning. The considerable variety of perspectives and theoretical formulations with which psychoanalysts perform their work can regularly be shown to relate to these features of the free association method. The implicit tension between the relational and self-observational components of the method of free association are reflected in the corresponding theoretical and technical approaches.

freedom

Freedom is the constitutive value of European political life, in that slaves, lacking freedom, must submit to a master, while free persons, being equal in respect of being free, constitute for themselves a government which secures order by law, and not by the unchecked will of a master. It is on this basis that Europeans have always distinguished their civil societies from the despotisms of the Orient, in which (according to the account commonly given in western political thought) all submit to a master.

Among the ancient Greeks, *eleutheria* was the adult condition in which a free male left behind the tutelage of childhood and took his place among fellow citizens in the public life of the *agora,* ruling and being ruled in turn. For the Romans, *libertas* was the quality of the free plebeian and corresponded to the *dignitas* of the patrician. The concrete reality of freedom for the Romans lay in their intense constitutionality, and their aversion, for many centuries after the expulsion of the Tarquins, to submitting themselves to a king. When the civic humanists of the medieval Italian cities revived the republican ideal, Julius Caesar stood as the man who extinguished freedom and gave Rome at last a master.

Medieval Europe, however, had its own indigenous sources of freedom, derived from both Christianity and from the practices of the barbarians who replaced the Romans. Regarding the situation in which one person rules another as sufficiently unusual to require justification (*omne potestas est a deo* was a common statement of the sentiment), they explored the forms of consent and the constitution of authority with great inventiveness: parliaments, juries, inquests the principle of representation and much else in what we call 'democracy' descend from the civil experience of that period.

In early modern Europe, these monarchical institutions and the classical republican tradition of freedom supplied a joint inheritance, and by no means a harmonious one. In the monarchical tradition, freedom was essentially a condition sustained by public life but enjoyed within the private realm. It came to be defined as a set of rights, which could be distinguished as the civil rights of the subject and the political rights of the citizen. Freedom, argued Thomas Hobbes, is 'the silence of the law', and, in this tradition, freedom has always resided in the ability of individuals, as judges of their own best interests, to order their lives within a structure of rules which are clear, predictable and known to all. The republican tradition, by contrast, took freedom as the moral ideal which identified being fully human with participation in public life. Active citizens, thus understood, were self-determining in that they participated in making the laws under which they lived. This view ultimately rested upon ideal memories of the virtuous and public-spirited cities of the ancient world. From Montesquieu onwards, many writers have judged that modern freedom, which is individualistic, is quite different from the

civic freedom of those earlier times, but the ideal of a truly participatory community has never lost its power to influence European thought.

It was Rousseau who most notably elaborated this latter view of freedom, with a clarity of mind which led him to the paradoxical implication that citizens who have been compelled to abide by a law for which they are in principle responsible are being 'forced to be free'. In the extreme development of this view, individuals can properly be described as free only when they act virtuously, which seems, in terms of the modern view of freedom, to be self-contradictory. These two views of freedom are often discussed, following Isaiah Berlin (1969), as the negative and positive view of freedom. The negative view tends to be strongly associated with Anglo-Saxon societies, while continental life is more receptive to the positive view.

The issue is important because the ideal of freedom has become the ratchet of European social and political development. Philosophers and politicians alike make use of slogans and images developed from the contrast between slave and free. 'Man is born free and everywhere he is in chains', begins Rousseau's *Social Contract* (1762), while Marx and Engels end the *Communist Manifesto* (1848) by telling workers that they have nothing to lose but their chains. Hegel argued in his *Philosophy of History* (1837) that a universal freedom has been the great achievement of the modern Germanic world. In the despotisms of the east, he argued, one was free; among the Greeks and Romans, some were, but in modern Europe, all were free. Indeed, within a few decades of Hegel's death in 1831, slaves had been freed throughout European possessions, and also in the USA. Paradoxically, it was in exactly this period that a new type of politician arose— communist, anarchist, nationalist and so on—to proclaim that modern Europe was, contrary to all appearances, the most cunningly contrived system of domination the world had ever seen. This doctrine launched the idea of liberation. But whereas freedom and liberty refer to the removal of arbitrary interferences with the way that individuals govern their lives, liberation was the project of removing *all* conditions thought to frustrate human satisfaction. It stands for a vision of human life in which desire flows freely and uninterruptedly into satisfying action. This is a vastly more ambitious project than that of liberty, and has appealed to a correspondingly less sophisticated audience.

Freud, Sigmund (1856–1939)

Ernest Jones, the foremost biographer of Freud, commented that Freud gave the world an incomplete theory of mind, but a new vista on man (Jones 1953–7). The insights that Freud arrived at and shared with the world changed and developed as he expanded his knowledge and understanding of himself, pursued his clinical work with patients, and broadened his interest in the world of science and letters. The perilous times in which he lived had a profound impact on his personal and professional life.

Freud was born on 6 May 1856 in Schlossergasse, Moravia, a small town in what is now Czechoslovakia (Freud 1959 [1925]). His parents were Jewish, and though he was an agnostic he always maintained his identity as a Jew. The family moved to Vienna when Freud was 4, and he lived there until 1938, when he and his family fled the Nazis to London (Hampstead). He died a year later, on 23 September 1939.

Although the family was not well off, no pressure was put on Sigmund, the oldest child, to seek a career that would be economically advantageous. Stimulated by Darwin's theories, he saw new hopes for understanding human nature. An essay by Goethe, 'On Nature', read at a popular lecture, sparked his interest in becoming a natural scientist and strengthened his desire to go to medical school. Freud's interests in social sciences, human interactions, developmental processes and ancient history were already evident during his childhood and youth; they were later to give richness to the discipline he founded: psychoanalysis.

At the university, he experienced serious disappointments. Yet the fact that his Jewishness made him an outsider seemed to strengthen his independence of mind. In Ernst Brücke's physiological laboratory, where he *was* allowed to work, he found role models he could respect, not only Brücke himself but also his assistants, Sigmund Exner and Ernst Fleischl von Marxow. Brücke asked Freud to work on the histology of the nervous system, which he did before undertaking his own independent research. In 1882, when he had been at the laboratory for six years, Brücke strongly advised him, in view of his 'bad financial position', to abandon his research and theoretical career for a clinical one.

Freud entered the General Hospital in Vienna, where he pursued his neurohistological interests at the Institute of Cerebral Anatomy, published several short papers, and was encouraged by Professor Theodore Meynert to devote himself to the study of the anatomy of the brain.

In 1882 Freud's friend Josef Breuer told him about his work with a patient suffering from hysterical symptoms. After putting the patient into deep hypnosis, Breuer had asked her to tell him what was on her mind. In her awakened state she could not repeat what she had revealed under hypnosis. The major contribution of the case of Anna O. (whose real name was Bertha Pappenheim) was the discovery of a technique that was a precursor to psychoanalytic treatment—free association.

In 1885 Freud won a travelling grant and went to Paris, where he became a student at the Saltpêtrière of the eminent neurologist, Jean-Martin Charcot. Freud's interest in Breuer's work had made him eager to find out more about Charcot's studies on hysteria. Charcot demonstrated quite convincingly the genuineness of hysterical phenomena and their conformity to laws, the frequent occurrence of hysteria in men (contrary to current theories), the production of hysterical paralyses and contractures by hypnosis, and the finding that artificially induced states showed features similar to those of spontaneous attacks that were initiated traumatically. Freud determined to study neuroses in greater depth. Before returning to Vienna, he spent a few weeks in Berlin in order to gain more knowledge of childhood disorders. During the next few years he published several monographs on unilateral and bilateral cerebral palsies in children.

In 1886 he settled in Vienna as a physician, married Martha Bernays, to whom he had been engaged for several years, and became known as a specialist in nervous diseases. He reported to the Vienna Society of Medicine on his work with Charcot, an account which the medical society did not receive with favour. Some of his critics doubted that there could be hysteria in males. In response to their scepticism he found a male with a classical hysterical hemianesthesia, demonstrated it before the medical society, and was applauded—but ultimately ignored. Once again he was an outsider. He was excluded from the laboratory of cerebral anatomy, had no place to deliver his lectures, withdrew from academic life, and ceased to attend meetings of the professional societies.

Freud's therapeutic armamentarium was limited. He could use electrotherapy or hypnotism. Since it became known that the positive effects of electrotherapy were in fact the effects of suggestion, Freud turned his sole attention to hypnosis. With this shift he thus became more firmly committed to psychological rather than organic treatment. He had observed in Paris how hypnotism could produce symptoms similar to hysteria and could then remove them again. In 1889 he went to Nancy where he observed the technique developed by Liébeault and Bernheim which used suggestion, with or without hypnosis, for therapeutic purposes. As he wrote in his autobiographical study (1925), '[I] received the profoundest impression of the possibility that there could be powerful mental processes which nevertheless remained hidden from the consciousness of men.' This was one of the first statements presaging Freud's monumental discovery of the unconscious.

In the early 1890s, Freud attempted to persuade Breuer to renew his interest in the problems of hysteria and to share with the world the discoveries he had made in the case of Anna O.*Studien über Hysterie* (1895) *(Studies on Hysteria)* was the result—a collaborative effort in which Breuer and Freud presented their ideas on the origin and treatment of hysterical symptoms. Freud described the unconscious in detail and introduced two key concepts: that a symptom arises through the restraining of a conflictful affect, and that it results from the transformation of a quantum of energy which, instead of being used in other ways, was converted into the symptom. Breuer described the way in which the technique he used with Anna O. allowed for the cathartic discharge of feelings (abreaction) with symptom relief. Although subsequent clinical research has questioned the universality of the effectiveness of this technique, it was *Studies on Hysteria* that introduced psychoanalysis to the world.

Breuer ultimately left the field of psychological treatment, but Freud, undeterred by the unfavourable reception given to the *Studies* by the experts of the day, pursued his studies

of patients. He discovered that what was strangulated in neurosis was not just any kind of emotional experience but those that were primarily sexual in nature. Freud then began to study the so-called neurasthenics as well as the hysterics. As a consequence of these investigations, he believed at that time that the neuroses, without exception, resulted from disturbances in sexual function.

Freud's study of Breuer's patient, Anna O., led to the discovery of the concept of 'transference', a key to clinical and applied psychoanalysis. In patients' relationships with their analyst, Freud thought, patients re-experience the early emotional relations that they had with their parents. It is the analysis of this transference that becomes the most fruitful instrument of analytic treatment. As a result of his discovery of transference, Freud abandoned hypnotism and began to use other procedures that evolved into the technique used in psychoanalysis today. The patient lies on a couch with the analyst sitting behind. The patient associates freely, and the analyst listens for patterns of transference, linkages, feelings, dreams, and other products of the associative process.

Once he had abandoned the use of hypnosis, Freud came to understand that there were forces which he called 'resistances' which kept certain patterns, linkages, and connections from awareness. An impulse barred from access to consciousness was in fact retained and pushed into the unconscious (that is, 'repressed'), from which it was capable of re-emerging when the counterforces were weakened or the repressed impulses strengthened. Freud considered repression a mechanism of defence, comparable to the flight mechanism used to avoid external conflict. In order to keep the debarred impulse repressed in the unconscious, the mental apparatus had to deploy energy. The amount of energy available for other non-conflicted activities was thereby depleted, and as a result symptoms appeared. The theory of repression became the cornerstone of the newer understanding of the neuroses, which in turn affected the task of therapy.

Freud's early 'topographic model' of the mind separated the unconscious into the preconscious and the unconscious proper. The topographic model was later to evolve into the 'structural model' of the mind, which consisted of the id, the ego, and the ego ideal, or superego.

As Freud investigated his patients' lives, he was struck by the significance of events that had seemingly occurred during the first years of childhood. The impressions of that early period of life, though buried in the unconscious, still played a significant role in the individual's personality and vulnerability to later emotional disturbance. Freud's assertion that sexuality is present from the beginning of life and has a subsequent course of development was a pivotal concept of psychoanalysis and one that evoked a good deal of controversy.

At the time of this discovery, Freud believed that experiences of sexual seduction in childhood were universally the basis of neurosis. The evidence for this was derived from his clinical work. Subsequently, however, he came to realize that the seductions had not actually taken place but were fantasies. That such wishful fantasies were of even greater importance than actual external reality, however, was one of Freud's most significant discoveries.

Freud's ideas of infantile and childhood sexuality became the basis of his developmental theory of sexual progression. Initially, he believed that sexuality is connected with what he called 'component instincts', that is, instincts which are

connected with erotogenic zones of the body but which have an independent wish for pleasure. These are usually connected with the vital biological activities necessary for survival. For example, oral activities involve sucking and feeding as well as oral pleasures; anal activities involve excretion as well as anal pleasures; and genital pleasures are related to reproduction and conception. Freud called the energy of sexual instincts 'libido'. In the course of psychosexual development, fixations of libido may occur at various points which may be returned to when later threats force a withdrawal to an earlier level. Freud called this process 'regression'. Freud also noted in *An Autobiographical Study* (1925) that 'The point of fixation is what determines the *choice of neurosis,* that is, the form in which the subsequent illness makes its appearance.'

The first object of libidinal gratification and fulfilment is the mother. Her breasts serve as the source of oral pleasure, and she takes on the significance of the external source from which later confidence, self-esteem, and self-regulation are derived. This relationship with the mother plays a pivotal role in a developmental stage that Freud named the Oedipus complex, after the famous Greek tragic hero. Using the male child as an illustration, and reducing this developmental stage to a simple formulation that did not take into account variations, complexities and consequences, Freud noted that boys focus their sexual wishes upon their mothers and become hostile to and rivalrous with their fathers. This incestuous object choice and its feared and fantasied consequences of genital damage and retaliation give rise to a stage of 'latency' during which the conscience (super-ego) becomes evident through feelings of morality, shame and disgust. At puberty, the earlier conflicts, including the Oedipus complex, may become reanimated. Although Freud's discoveries of the sexuality of children were made from the psychoanalyses of adults, direct observation of children as well as the analyses of children and adolescents have confirmed, extended, detailed and modified his ideas.

Freud also made a major contribution to the study of dreams—their meaning and their use in the therapeutic situation. In one of his major works, *Die Traumdeutung* (1900) (*The Interpretation of Dreams,* 1913), Freud described his researches on dreams, dream work and formation, symbolism, and his wish-fulfilment theory of the function of dreams.

In *Zur Psychopathologie des Alltagslebens* (1904) *(The Psychopathology of Everyday Life),* Freud turned his attention to slips and lapses of memory. Such symptomatic acts, so common in everyday life, he believed, have meaning, can be explained and interpreted, and indicate the presence of conflicting impulses and intentions. The study of dreams and of symptomatic acts has applicability to both pathological situations and normal healthy mental functioning.

For ten years after he and Breuer parted (1895–6 through 1906–7) Freud worked in isolation, rejected by the German-Austrian establishment. In 1900–2, however, Bleuler and Jung, working at the Burghölzli, a large hospital near Zurich, became interested in psychoanalysis and began to extend the application of Freudian theories beyond the confines of upper-middle-class Vienna.

In 1909, Freud, Jung and Sandor Ferenczi, a member of Freud's circle in Vienna, gave lectures at Clark University in Worcester, Massachusetts. James J. Putnam, a neurologist at Harvard, and William James were among those present. The trip was a success, and marked the beginning of international recognition. In 1910 the International Psycho-

Analytic Association was founded, an organization that still exists. Several journals, institutes and societies were organized in Vienna, Berlin, Moscow, New York, Zurich and London.

Although many of the earlier pioneers remained loyal to Freud and to psychoanalysis, some of his followers ultimately left him to found their own movements (for example, Adler, Jung, Reich, Rank and Stekel).

Freud's research continued at an intense pace, but gradually his students and colleagues took over increasingly from him. In 1923 he became ill with a malignancy of the jaw which was to give him pain and anguish for the rest of his life. His contributions to our understanding of art and artists, literature and writers, jokes, the psychology of religion, anthropology, myths and fairy tales, rituals, the emotional aspects of group psychology, philosophy, education, childcare and rearing, and the question of educating non-physicians to be psychoanalysts were some of the by-products of his lifelong struggle to penetrate the science of the mind.

Freud was a brilliant and a learned man, a researcher, clinician, theoretician and writer. Psychoanalysis allowed us to understand what previously was seen as irrational human behaviour from a new perspective. His contributions to psychiatry, psychology, sociology and biology are monumental. The science of psychoanalysis has moved on since Freud's time, correcting some of his errors and expanding into areas that he did not develop. One can only do so much in a lifetime, and Freud gave us so much that it will be many lifetimes before we have fully understood him.

Friedman, Milton (1912–)

Since 1950, Milton Friedman has Been a leader of international monetarism, methodological positivism and traditional liberalism, as well as of the so-called Chicago School which embodies these ideas. He was Nobel Laureate in 1976; his presidencies include the American Economic Association and the Mont Pelerin Society. His best-known book among the general public remains probably *Capitalism and Freedom* (1962), followed by selections from his *Essays in Positive Economics* (1953) and his *Monetary History of the United States* (1963, with Anna J.Schwartz).

Born in New Jersey of immigrant parents, Friedman was trained almost simultaneously in mathematics, economics and statistics (AB Rutgers University, MA University of Chicago, PhD Columbia University). He was initially known primarily as a mathematical statistician specializing in decision theory. His broader interests in economic theory, history and methodology became apparent in university teaching at the Universities of Wisconsin (1949–50), Minnesota (1945–7) and Chicago (1947–77), and dominate his later work. Since his retirement from Chicago, Friedman has been affiliated with the Hoover Institute on the Stanford University campus in California.

Friedman the methodologist believes that the widely ridiculed differences of opinion and advice among economists relate primarily to questions of *what is* (positive economics) rather than of *what should be* (normative economics), and that once the positive questions are satisfactorily answered the normative ones will be manageable. Friedman maintains that questions in positive economics can in principle be answered at least tentatively by comparing (evaluating) the quantitative predictions, which themselves result from alternative 'models' of how the world—or the economy—works. It makes no difference to him whether the basic assumptions underlying these models are or are not themselves intuitively realistic; also, any general case theory, into which wide ranges of alternative results fit equally well as special cases, is untestable and thus of little value.

Friedman's monetarism and his 'modernized' quantity theory of money illustrate his methodological position. He interprets the quantity theory as a theory of nominal income, and as maintaining only that the quantity of money in a country (however defined) is a more accurate determinant of both the levels and changes of that country's nominal income than is the country's autonomous expenditures, in the sense of Keynesian theory. As for the division of nominal-income effects between real income and the price level and, also, as for the precise structure relating money and income, the quantity theory (in Friedman's version) has little to say. We should also note that Friedman has favoured exchange-rate flexibility, whereas most international monetarists prefer a fixed-rate system.

In their *Monetary History of the United States* and related works, Friedman and Schwartz apply their monetary insights to the period since the American Civil War, tracing changes in both price levels and business activity to monetary uncertainties—fluctuations of monetary growth above and below any smooth relationship with the long-

term growth rate of the real economy. It contains two disconcerting results. First, the inauguration of the Federal Reserve System in 1914 seems to have made things worse rather than better than they were previously—Friedman favours 'rules', including the pre-1914 gold standard, over 'authorities', like the Federal Reserve Board, as regulators of the money supply. Second, the main explanation for the depth and the persistence of the Great Depression of the 1930s is a series of errors in Federal Reserve policy, whose fears of 'going off gold' permitted the US money supply to fall by approximately one-third over the three-year period following the stock-market collapse of October 1929, without preventing the USA's departure from the gold standard.

Friedman's overall liberal faith in the market as an economic regulator is a matter of 'second best' and does not regard market determinations as Utopian. This liberalism arises primarily from Friedman's understanding and interpretation of the record of intervention, extending even to attempts like the US Anti-Trust Laws at enforcement of closer approaches to 'pure and perfect competition' upon an imperfectly competitive market-place. Friedman's negative judgement embraces both the errors of well-intentioned voting majorities and of well-intentioned intellectual meritocrats, along with the errors of tyrants, dictators, and despots. A secondary Friedman argument for the market is the shelter that its anonymity offers to social, religious, racial and ideological minorities doomed to failure so long as success requires employment of licensure by the majority or by the Establishment. At the same time, Friedman's liberal individualism does not go so far as the 'libertarianism' of some other American writers for whom the state is illegitimate and taxation, in particular, is robbery. Friedman's major concession to the contemporary (twentieth-century) concept or distortion of liberalism has been his advocacy of a minimum income below which individuals and families should not be required to fall, but which should replace the myriad of social services programmes embodied in the contemporary welfare state.

functional analysis

The terms functional analysis and functionalism are often equated, yet to equate them is to beg a number of questions, is misleading and perhaps even mistaken.

Functionalism is a doctrine which asserts that the principal task of sociology and social anthropology is to examine the contribution which social items make to the social and cultural life of human collectivities; it may additionally assert that to examine social phenomena in this way is to explain why those items occur at all, and/or why they have persisted.

Functional analysis is a method of sociological or anthropological enquiry which consists in examining social and cultural items by locating them in a wider context. This usually means showing how these items affect and are affected by others with which they coexist over time.

From these descriptions it is clear why the doctrine is named functionalism: it claims that cultural phenomena either have uses, and otherwise would not endure, or that they come into being, and then persist, because they are useful. But it is not initially clear why a method of examining cultural phenomena within the context of other such items should be called functional, in the sense of 'useful'. The most obvious reason is that functional analysis has been seen as so necessary to functionalism that the two have been treated almost as one. To explain the function(s) of a social item does itself require locating it within the context of a wider system or subsystem. For example, in order to show that the function of kinship terminology is to express the shared recognition of a set of kinship categories, which are necessary to sustain rules of co-operation, alliance, marital eligibility, succession, inheritance, and so on, one has to examine kinship terms of reference and address in the contexts of rules governing different degrees and directions of kinship interaction. So much is obvious. What is not at all obvious is that the practice of functional analysis also presupposes that the doctrine of functionalism is true: in short, from the decision to locate the use of kinship terminology within the context of its various uses, it does not follow that terminology owes its existence to those uses; it might be equally plausible to argue that the usages are consequent upon linguistic rules.

Here we encounter a second article of faith endorsed, unquestioningly in some cases by earlier functionalist anthropologists: that in the absence of written histories, or other reliable clues to the past, one must assume that some features of the here-and-now must be taken as given and as accounting for others; and that both sets of features are readily identifiable. For example, it would be assumed that the level of technology, the system of ordering economic and political relations through kinship, and the form of that kinship system could be taken as given, and that certain other practices, such as linguistic and ritual norms (symbolic representations) could be explained as functioning to maintain those given features of social and cultural life.

Furthermore, it seems also to have been assumed that the effectiveness of the method of functional analysis attested to the strength of the theory, and that the theory justified the method.

Whether or not the theory could have justified the method, what did justify it were two sets of circumstances in which ethnographers of preliterate societies worked. First, they dealt with societies with no written records and, it was often believed, with no other clear evidence which could illuminate the past and, consequently, the processes whereby the societies' existing features could have developed. Thus it seemed that all that ethnographers could do well was to examine certain existing practices and beliefs in their context, so as to make sense of them in comparison with the practices and beliefs of the

societies in which ethnographic reports would be read. Second, they dealt with societies which, unlike their own, were relatively simple and slow-changing and, therefore, in which there appeared to be a high degree of interdependence of the different features of social and cultural life (Cohen 1968).

To qualify the first point, the absence of evidence for recounting reliable histories of certain societies had not inhibited the anthropological precursors of functionalists from constructing histories that were informed either by the theory of evolutionary parallelism or by that of diffusionism. Functionalism and functional analysis emerged in reaction to these so-called histories. Given the reaction against these seemingly untestable theories of pseudo-history and, moreover, their distracting effect on the examination of the here-and-now, it is likely that the commitment to functionalist doctrine was regarded not only as a necessary justification of the method, but also as a rationalized refutation of the two doctrines of conjectural history.

To qualify the second point, it should not be thought that functionalists explicitly acknowledged the greater interdependence of different features of social life to be found in the technologically simpler and smaller-scale societies. Rather, it can be said that the significant degree of functional autonomy possessed by different features of social life in most complex societies is expressed in a language which treats different areas of social and cultural activity as separable, even when they are not altogether separate. This language, fashioned not for self-conscious social scientific discourse, but, rather, for everyday use, was imposed on societies within which such categories were for the most part foreign. Thus, certain activities were separated out by the use of the ethnographers' taken-for-granted language and then shown to be more or less strongly interrelated. But few, if any, such ethnographers recognized that the degree of interconnectedness which constitutes a social and cultural system might itself vary from one such system to another. Moreover, some interpretations of the method encouraged an undue emphasis on the degree and nature of the interconnectedness of social and cultural phenomena in even the simplest societies, and, also, promoted an even greater error in the excessive search for it in more complex societies.

The almost casual equation of method and doctrine by some social anthropologists was highly misleading: the doctrine that functional analysis could also yield explanations of the existence of social and cultural phenomena was in many instances not even demonstrated, and was, in any case, at worst erroneous and at best confusing.

But what use of functional analysis of the here-and-now has ever explained why the Bemba are matrilineal, why the Tallensi have no centralized political authority, why the Nuer have a form of monotheism, or why some Australian aboriginal societies have moeities and others, in almost the same physical environment, do not? While a functional analysis of Nuer feuds might be thought to account for their forms by showing how these forms serve to maintain particular patterns of kin-based alignments, it could hardly account for the segmentary structure of that society. Of course, if one knows that the Nuer have a particular type of segmentary structure, characterized by particular processes of alignment and division, that knowledge might help explain why, if certain other conditions remain constant, that structure tends to perpetuate and to resist transformation into a more centralized type of society. Such an explanation of social reproduction—which could be called an equilibrium analysis, since it shows that the processes which

inhere in this type of structure are self-correcting with regard to the non-centralization of power—does not itself rest on any part of the functionalist doctrine.

As philosophical critics, followed in turn by social scientists, have long shown, those explanations of social phenomena which are truly and simply functionalist are seriously flawed: they are ideological in that they account for items by examining their positive consequences in maintaining a wider system of which they are a part; and they reify such systems by treating them as though they were either mechanical or organic wholes (Nagel 1956).

The only reply to such critics is to argue that functional analysis may demonstrate a continuous, circular flow of causes and effects—that is, of so-called feedback processes—which show how a system persists, and therefore explains why particular items are to be found at a particular time and place. But even if this can be done convincingly—and it requires empirical confirmation, not simply an intuitive judgement that coexisting phenomena must interrelate in this self-maintaining way—it hardly attests to the value of a functionalist doctrine. Rather, it illustrates the point that social and cultural persistence may in some cases be explained in terms of 'systemic feedback' or, if one prefers, in terms of benign chains of cause and effect which are at some points recursive.

But, of course, the outcome of such causal chains may not be benign, at least to some sections of a society. For example, the educational systems of (most) industrial societies favour the children of the advantaged, whose environments not only facilitate educational performance but may also strengthen and channel motivations to succeed in it. But, since structured inequalities of performance contradict the principle of equality of opportunity, it could be argued that while the system 'functions' for the advantaged it does not do so for the disadvantaged and, especially, not where the latter are aware of the discrepancy between principle and reality. However, ardent functionalists might show that the system works effectively at creating only a low level of motivation among those who are least likely to succeed and, thus, in this way *does* function to maintain both itself and a degree of wider social stability. It could be said that the symbols of alienation with which the disadvantaged young adorn themselves signify an ill-contained and, perhaps, ill-defined discontent which they occasionally express in more overt fashion. But then one could also argue that those expressive symbols also serve the wider system, and so on (Merton 1949).

But what of those situations in which the working of the system benefits no one? In some circumstances of low, or even zero, economic growth, the institutionalized forms of conflict over income levels and differentials could become so intensified as to contribute to a negative growth rate and to an uneven but overall fall in real incomes. One could argue even here that the seeming dysfunctions of the systems are, after all, functional for it: since the contending parties cannot unite to change a system which no one wants in its existing form, their inactions contribute to its persistence.

What such an example demonstrates is that the term functional, meaning 'useful', pertains only to those circumstances in which the gratification of the conscious or unconscious motives of social actors is (intentionally or unintentionally) facilitated by certain enduring practices, which sustain those motives, and which in turn contribute to the continuation of the practices themselves. No other use of the term can be permitted.

Certainly, to refer to social practices as functioning to maintain a system, regardless of whether any groups or collectivities have an interest in maintaining it, is either to state the obvious—that a system persists—or it is to beg the very question that needs to be answered. If the answer is negative, then either the use of the term function creates a self-contradiction or it is meretriciously redundant.

What has been called functional analysis should, in fact, be seen as a particular form of the systems approach in the social sciences. To state that there is a system is to imply that discernibly separable processes interact so as to endure in this state over a period of time. To enquire as to why particular features of that system persist is to locate those features in the wider system. To establish that some social practice, which is part of a system, gratifies the motives of some social members, is to ascribe a function to that practice.

futurology

Futurology is not so much a social science as a social movement that sprang up in Europe and North America in the late 1950s and has since spread throughout the world. Its pretensions are scientific: to predict future developments in society by an intensive study of past and present trends. In this it follows the lead given by the first systematic futurological exercise, H.G.Wells's *Anticipations* (1901). From Wells, too, it takes its strongly technological bias, as reflected in the *chef d'oeuvre* of the movement, Herman Kahn and Anthony Wiener's *The Year 2000* (1967) and *The United Kingdom in 1980* (1974). But beyond this general orientation there is no agreement on scientific method, as revealed by the variety of techniques practised by its numerous acolytes. These range from imaginative, one-off shots, like Michael Young's satirical *The Rise of the Meritocracy* (1958) and Dennis Gabor's *Inventing the Future* (1963), through the

civilized speculations of Bertrand de Jouvenel's *The Art of Conjecture* (1967), to the solemn computer-based team reports such as the EC's *Europe 2000* projections, and the Club of Rome's *The Limits to Growth* (1972). A notable contribution from eastern Europe in the latter vein is the report of Radovin Richta's Czech team, *Civilization at the Crossroads* (1967). Somewhere in the middle come the projections and speculations of experts working from their home disciplinary bases, as in the collections edited by Daniel Bell, *Towards the Year 2000* (1968), and Robert Jungk and Johan Galtung, *Mankind 2000* (1969). The centrality of technology in futurological thinking is underlined by the movement's frequent reference to Erich Jantsch's *Technological Forecasting in Perspective* (1967), which is for many the Old Testament, if not the Bible, of futurology. Other popular techniques include a kind of team game known as Delphi forecasting, where experts revise their initial forecasts in the light of forecasts by other members of the team. The results are understandably not usually very exciting.

Most products of futurology, again following Wells, breathe a spirit of confidence, not to say complacency. They look forward to a 'post-industrial society' or even a 'super-industrial society', where the fruits of applied science have produced an era of leisure and abundance. The basic expectation seems to be that the future will be the present writ large. Some form of extrapolation is the method common to most futurologists, and given that the movement received its main impetus in the prosperous years of the 1960s, it is hardly surprising that the future appears largely as a bigger and better version of the 1960s, above all in the technological sphere. Differences of ideology and values are played down, in the belief that the technological imperative largely commands social systems. Here futurology shows its kinship with certain kinds of science fiction and utopianism; but an added and somewhat spurious dimension of serious science is given by the team and think-tank basis of much of its activities. This has made it attractive to governments, the more especially as it appears to offer the materials for long-range planning, and also because much of the thinking has been about 'the unthinkable', namely the prospect and possibility of nuclear war. Large private corporations have shown interest for the same reasons, and some, such as Shell, Unilever and Xerox, have themselves gone in for large-scale exercises in futurology.

In the wake of the oil crisis of 1973, and the world recession of the later 1970s, something of the gloss has gone off futurological speculation. There has been greater readiness to include the thinking of alternative and radical futurologists, especially those of an ecological persuasion. Groups such as Friends of the Earth, and magazines like *The Ecologist,* can see many of their ideas taken up in mainstream futurological journals such as *Futures* and *The Futurist.* In addition to the physical limits to growth indicated by the Club of Rome report, there has been a new awareness of the 'social limits to growth', as persuasively discussed in Fred Hirsch's book of that name (1977). The world no longer seems quite so amenable to western patterns of development, nor indeed so open to western or Soviet penetration. Fears about nuclear war have revived. The rosy glow that hovered over the millennial year 2000 now carries a more apocalyptic connotation. Futurology has not given up all the hopes implicit in its supposedly neutral scientific enterprise; but it has come to balance these with a greater realization of the limited historical and cultural context that inspired it in the heady days of the 1960s.

G

game theory

The theory of games is a branch of mathematics devoted to the study of interdependent decision making. It applies to any social situation in which there are two or more decision makers, called *players,* each with a choice of two or more courses of action, called *strategies;* the outcome depends on the strategy choices of all the players; and each player has well-defined preferences among the possible outcomes, so that numerical payoffs reflecting these preferences can be assigned. Games such as chess and poker, together with many social, economic, political and military conflicts which are not commonly thought of as games, possess these properties and are therefore amenable in principle to game theory analysis. The primary goal of the theory is to determine, through formal reasoning alone, what strategies the players ought to choose in order to pursue their interests rationally, and what outcomes will result if they do so.

Although some progress was made by Zermelo in 1912, and by Borel during the early 1920s, the theory was not firmly established until John von Neumann proved the fundamental minimax theorem in 1928. This theorem applies to two-person, strictly competitive (zero-sum) games, in which one player's payoffs are simply the negatives of the other player's. If the number of strategies is finite, and the players are permitted to use randomizing devices to 'choose' weighted averages of their strategies, then each player can adopt a strategy that yields the best payoff given the most damaging counter-strategies available to the adversary. The minimax theorem asserts that these payoffs are equal, and that every game of this type therefore has a well-defined solution.

Applications of game theory in the social sciences have focused chiefly on non-zero-sum games. A famous example is the two-person *Prisoners' Dilemma,* identified in 1951 by Merrill Flood and later explicitly formulated and named by Albert W.Tucker. This

game has the paradoxical property that whereas each player has a *dominant* strategy that yields the best payoff against both of the opponent's available counter-strategies, each player obtains a better payoff if both choose *dominated* strategies. A multi-person generalization of this, the *N-Person Prisoners' Dilemma,* was discovered in the early 1970s; in this game, every player is better off if all choose dominated strategies than if all choose dominant strategies. The N-Person Prisoners' Dilemma is a model of many familiar social problems, including resource conservation, wage inflation, environmental pollution, and arms races.

Experimental games have been used by psychologists to study co-operation and competition in two-person and multi-person groups, and economists have applied game theory to the study of bargaining and collective choice. In political science and sociology, game theory has been used to analyse voting behaviour and coalition formation, and numerous other applications of the theory in social anthropology and other fields have been attempted. During the 1970s, applications of the theory to the study of the evolution of social behaviour began to flourish in sociobiology.

game theory, economic applications

Game theory is concerned with situations in which several decision makers interact, in the sense that the degree of satisfaction achieved by any one of them depends not only on his or her choices but also on the choices made by all the other players. Situations of this type are referred to as 'games'. Game theory tries to define what would be *rational* in the context of such a game, and it tries to predict the *actual* behaviour of the players.

Games are pervasive in economic life. Examples of economic games are the interaction among employees within a firm, the rivalry among firms operating in the same market, the negotiations between a firm and its suppliers, and the economic policy-making of governments in interdependent economies. The inventors of game theory recognized early that it was applicable to economics, but it was only in the 1980s that game theory became widely used in the field. It is now one of the most frequently used research tools in economics.

Game theory is divided into co-operative and non-cooperative branches, the distinction being that co-operative game theory assumes that decision makers can enter into binding agreements about their strategies, whereas non-cooperative game theory assumes that no such agreements can be made. Initially, it was mainly co-operative game theory that attracted the attention of economists, but non-cooperative game theory has become more important.

To see how game theory can be applied in economics, consider as an example the situation where different firms, competing in the same market, must make decisions about the choice of products, the prices to charge buyers, the extent of advertising, etc. Can firms be induced through competition to make choices that serve the interests of buyers even if this is at the expense of profits? Game theoretic analysis predicts that small groups of firms operating in transparent environments can maintain high profits and evade the forces of competition even if no binding, collusive agreements are permitted. Typically, the firms involved will develop accepted norms of behaviour, with the implicit threat that deviants will be punished through aggressive competitive behaviour. Such punishments are easier to implement in more transparent markets, which suggests that the transparency of markets may not be socially desirable.

Often the terms of economic transactions are not determined through market competition but are an outcome of bilateral bargaining: for example, wages which are negotiated between trade unions and employers' organizations. In this context, game theory has illuminated the precise way in which factors like patience or the willingness to take risks contribute to the success of a negotiator. Negotiators may be advantaged if they can create the impression that they have an alternative option, excluding the other party, should negotiations fail. This threat may not work, however, if it can be shown to lack credibility, for example because such an option would be less desirable than any outcome of the negotiations that could reasonably be anticipated. Game theory has clarified the distinction between credible and empty threats in bargaining.

Other examples of economic applications of game theory range from the analysis of the internal structure of firms to theories of economic policy-making in an international context. One of the major fields of application concerns games in which some participants lack important pieces of information. Beginning in the 1970s, economics has become increasingly concerned with the question of information, and a field known as 'economics of information' has developed, which, for example, studies markets in which goods come in different qualities, and in which buyers cannot observe quality before buying. This may drive high-quality products out of the market, or it may force the suppliers of such goods to make special efforts to distinguish themselves from other suppliers. Game theory has had limited success resolving the problems raised by the economics of information, since the predictions that emerged from its application were not adequately specific. Whether this difficulty can be resolved, perhaps by refining the notions of game theory, is the subject of ongoing research.

gangs

The term 'gangs' has been used to refer to groups ranging from 'play groups' (as in 'that old gang of mine') to groups of organized criminals. As a public concern, the term refers to troublesome groups, usually of young people. Controversy over definition of the term focuses on whether to include criminal behaviour and self-identification in the definition of gangs. Reduced to the simplest terms, youth gangs are *non-adult-sponsored adolescent groups,* that is, groups whose members meet together somewhat regularly, and over time, on the basis of *self-defined* criteria of membership (Short 1990). Identification with a 'hanging' or 'ranging' area typifies *street gangs,* while adult-sponsored groups typically identify with an institution, such as a school, church or agency.

Distinctions between adult-sponsored groups and gangs, and between gangs as a generic category and street gangs constitute the beginnings of a typology of gangs. The need for such a typology is great, in part because media portrayals, law-enforcement strategies and common public perceptions often blur distinctions between gangs that are critical both to understanding and to control of gangs.

Among the most troublesome behaviours associated with gangs, for example, are violence, drug use and drug trafficking. While there is strong evidence that many street gang members use and sell drugs, there is little evidence that street gangs play a major role in drug selling. Successful drug selling requires strong leadership, organizational skills, and cohesiveness, as well as focused efforts on drug sales and avoidance of other criminal involvement, none of which characterizes most street gangs (Klein 1994). While violence is common among both street gangs and drug gangs, among the former it is mainly about status (within as well as between gangs); among drug gangs violence is a means of controlling markets and enforcing discipline among gang members and payment by customers.

A substantial body of research suggests that street gangs become delinquent/violent as a result of, first, conflict with rival groups, often involving competition or conflict over territory or status-enhancing behaviours (e.g. graffiti, dancing or athletic contests); second, definitions or actions of others that push a gang identity on the group; and, third, group processes that create/reinforce group cohesion based on delinquent/ violent

behaviours. The last often involves individual and group status considerations.

Systematic research on youth gangs began only in the second half of the twentieth century. A complete typology of gangs is not yet possible, and any such attempt confronts a number of daunting tasks, including further distinguishing among a multitude of groups (e.g. 'wilding groups', skinheads, bikers, taggers, stoners, and many others), and specifying the nature of relationships between such groups and adults, which research suggests is of critical importance. A typology of gangs must not be static, because new forms and behaviours among such groups occur frequently. It must provide a basis for understanding changes in gang orientation and behaviour, e.g. how tagger groups become street gangs and how drug gangs evolve from street gangs. We know that such transitions occur—and that previously essentially non-delinquent gangs sometimes become more heavily involved in delinquent behaviours—but we know little about how and why they occur.

The existence and continuity of gangs is heavily influenced by forces external to the gang, including macroeconomic forces. In the USA and in some other countries, for example, the declining industrial base of some cities has resulted in persistent and pervasive poverty in inner-city communities. The impact on young people and on family and community life has been devastating. Among the hypothesized results are that street gangs have proliferated in the USA and are found in some cities in other countries where similar social and economic conditions exist. Many gang members continue gang affiliation well into adulthood, in some cases transforming the youth-oriented quality of street gangs into more economically instrumental gangs. Without systematic, rigorous research concerning the impact of social and economic changes such as these, there is little prospect of greater understanding and control of gangs.

GATT

The General Agreement on Tariffs and Trade (GATT) is a treaty between states (contracting parties) under which they undertake to adhere to specific rules and principles relating to trade policies and to participate in periodic rounds of multilateral trade negotiations (MTNs) to lower trade barriers. MTN rounds have in fact lowered average tariffs substantially, restricted domestic pressures for protection and contributed significantly to post-war reconstruction, growth and globalization of the world economy. From its creation in 1947, GATT has evolved from a replacement for the stillborn International Trade Organization into a pillar of the international trading system. Under the Uruguay Round agreement (1994) it will be subsumed into the World Trade Organization (WTO) in 1995.

The WTO is to oversee the GATT, as well as two further agreements arising from the Uruguay Round: the General Agreement on Trade in Services (GATS) and the Agreement on Trade-related Intellectual Property Rights (TRIPs). The GATT will continue as a separate body concerned with trade in goods, indeed with its range of influence expanded and basic disciplines reinforced.

The influence of GATT has increased steadily over time, as the number of contracting parties (over 120 by 1994 and set to grow further as more developing and eastern European countries join) and as the policy instruments subject to GATT rules have increased. Agricultural and industrial producer lobbies, consumer associations and political parties are concerned with the outcome of MTNs. As a result, GATT and MTNs are the focus of major political debate, national and international, and of the mass media.

There are a number of possible reasons for GATT's longevity as an institution. There has, for instance, been a significant momentum for trade liberalization during much of the post-Second World War era, particularly up until the first oil shock of 1973–4. Memories of the beggar-thy-neighbour policies that were pursued in the 1930s have remained sufficiently vivid. This historical perspective has been reinforced by the experience of the growth of incomes in the major trading nations that accompanied liberal trade policies. Clearly trade liberalization was not the sole factor at work here, but the association between trade liberalization and growth has certainly not been harmful to GATT's status.

The Articles of the GATT unambiguously call for open markets and the use of transparent and non-discriminatory policies so as to foster free and fair competition in international trade. In practice GATT has tended to be a rather more pragmatic and flexible institution. The MTNs have largely ignored at times certain sensitive issues, such as protectionism in agriculture and textiles, or have introduced different treatment for special cases such as the developing countries. Similarly GATT rules have often been broken by contracting countries without GATT trying to enforce its obligations, in order to avoid serious conflict between important members. In large part this has been a reflection of the nature of its relatively small, Geneva-based secretariat, which has had limited power and resources to police the international trading system and has had

therefore to serve the wishes of its members, in particular its most powerful members. But GATT has demonstrated a capacity to respond to new challenges and to widen its competence. Initially largely restricted to customs duties, GATT first shifted its attention to other non-tariff measures in the Kennedy Round (1964–7) and now is more concerned with regulating the use of a potentially enormous array of non-border controls (including subsidies, competition policies and anti-dumping procedures) that may be used by national governments to restrict international competition. Following the Uruguay Round and the creation of the WTO, that competence and power to regulate the trading system is likely to increase.

gender and sex

The study of gender has its roots in the anthropology of women and for this reason is often mistakenly taken to be solely about women. Gender studies, however, are concerned with the cultural construction of embodied human beings, women and men. They examine the differences and similarities as experienced and interpreted in various contexts, taking this to mean all relationships whether they involve subjects of the same or different genders. Gender has often implied and/or been contrasted to sex, the biologically defined categories of male and female.

Despite the fact that the biologically determining nature of sexual differences had been questioned by Margaret Mead as early as 1935, gender studies began essentially in the 1960s with the growing awareness of the need to 'write women into' male-biased ethnographies. This women-centred approach, the anthropology of women as it came to be known, did not, as Moore (1988) notes, arise from the absence of women in the traditional ethnographies, but was rather due to a growing concern that women and their world-views were not being adequately represented.

In order to redress this imbalance, women's views had to be heard in the ethnographies. It was felt that women researchers, as women, were more capable of approaching and understanding women in other cultures. Underlying this belief was the view, often identified as essentialist, that there exists a universal women's nature: that despite cultural variations, biological sexual differences are stable and pre-social and are

reflected in the socially constructed gender categories, men and women.

Many anthropologists felt that this position was untenable. In order to avoid the ghettoization that would occur with an anthropology of women, and equally important in order to surpass past, male-biased theories and biological determinism, they had to develop new theoretical and analytical approaches. They had to shift their interests from the study of women to gender studies, that is, to the study of women and men. In constructionist terms they asked how sexual differences were constituted through social and historic discourse and interaction. The question which remained central to their thesis was why and how women in nearly all societies seemed to experience some form of subordination to men.

One of the first to adopt such an approach was Edwin Ardener (1972). He proposed a theory of 'muted groups' in which dominance was explained as a group's ability, the group often identified with men, to express a world-view while in turn muting alternative, often women's, models. Other authors noted the western bias for language as a means of expression often controlled by men, as opposed to other non-verbal forms of expression such as bodily gestures, weaving and cooking. Furthermore, anthropologists, both men and women, use male models which have been drawn from their own culture to interpret models present in other cultures.

By pointing out that women anthropologists were not necessarily privileged in their studies of women of other cultures, researchers were able to pursue the study of gender as a cultural and sociological construction. Two theoretical approaches can be discerned in the study of the position of women and of gender. The first, influenced by Engels's distinction between production and reproduction and his analysis of the sexual division of labour, took economic relations as central to its thesis (1972). This approach preceded the anthropology of women but later fed into the study of gender. The second based its analysis on the separation between nature and culture, rooted in the works of Freud and Lévi-Strauss.

Marxist-oriented researchers (e.g. Leacock 1972; Reiter 1975; Sacks 1974) associated the subordination of women with the domestic/public dichotomy and the sexual division of labour. This analysis aligned the subordination of women with their exclusion from the public sphere of production and their subsequent rele-gation to reproductive labour within the household. They sought to explain women's position in society on the basis of women's access to the means of production. This view proved to be too narrow and ethnocentric, its theoretical premises rooted in industrialized, class-based societies. For example, some anthropologists noted that in hunter-gatherer societies where there is no sharp distinction between the public and private domains, the sexual division of labour is not based on relations of inequality and asymmetry but on relations of complementarity. Other ethnographic evidence showed how women often took part in both productive and reproductive labour. Although the definition of reproduction was expanded in some instances to include social reproduction, the subordination of women was still often linked to their role in biological reproduction.

By contrast, adopting a structuralist approach and in line with Simone de Beauvoir's position, Sherry Ortner (1974) argued that women's universal subordination was a result of their association with nature due to their ability to bear children, whereas men were everywhere associated with the implied superior domain of culture and its production.

Michelle Rosaldo (1974), in the same vein, pointed out that women were identified with the domestic domain because of their roles as mothers. She stressed the distinction between the ascribed status of women and the achieved status of men. For Rosaldo, women could overcome their subordinate role only if they moved out of the domestic and into the public, male domain.

These propositions were widely criticized for making too simple a universalisation. For example, in MacCormack and Strathern (1980), the contributors showed that the structuralist dichotomy between nature and culture was a western construct, historically constituted. In many societies, it was noted, this dichotomy was differently constructed and in some it was questioned whether it existed at all. Rosaldo (1980), too, later modified her position noting that the distinction between the domestic and the public could not necessarily be universally applied.

In view of this critique, gender categories and the relations between gender have to be understood in a different manner. Ortner and Whitehead (1981) proposed that gender could be understood as 'prestige structure' and had to be correlated with other systems of social evaluation. Errington (1990), for example, notes that in island South-east Asia, the differences between men and women are not highly marked. This may be due to their social invisibility to western-trained researchers. It might also have to do with how Euro-Americans define power and status. Women in these societies have instrumental power and control over practical matters and money. Yet their economic power may be the opposite of the spiritual power which brings the greatest prestige.

In short, the universals that had been proposed, that is the dichotomy between nature and culture, and its companion, domestic and public, had been questioned and undermined by the ethnographic evidence. Similarly questioned was the universality of such categories as subordination and inequality since these categories were shown to be context bound. Also brought to light were the multiple experiences of women and men, even within the same society. Women of different race, class and ethnic backgrounds did not necessarily share the experiences of white, middle-class women. It also challenged those theories which viewed the categories of women and men as universally given. Gender categories, it was argued, had to be observed and interpreted within a particular time and place.

Of equal importance was that the sex categories, male and female, were increasingly being viewed as presumed rather than proven by researchers. It was increasingly becoming evident that though the distinction between biological determined sex and culturally determined gender had assisted researchers in examining the relations between men and women and in viewing gender categories as socially and culturally constituted, this dichotomy in the end echoed that of nature and culture. Sex, as biologically given and therefore pre-social and causally prior to gender, was being challenged (Caplan 1987).

Social historians, prominent among them Michel Foucault (1978), laid bare the historical construct of sex as a western category. Laqueur (1990) for example notes how recent the two-sex model of Euro-America is. For centuries people held a one-sex model in which women were seen as inverted men. The two-sexed model developed not only in consequence of the dominance of the Cartesian model but also due to the growing power of biomedical discourses (see also Scheper-Hughes and Lock 1987).

In line with Schneider's critique on kinship (1968, 1972, 1984), Yanagisako and Collier (1987) argued that the two different and exclusive biologically defined categories, male and female, are derived from the Euro-American folk model of heterosexual reproduction—the same model underlying concepts of kinship. Therefore, in order to free ourselves from the blinkering category of sex, Collier and Yanagisako proposed that the study of gender should be disengaged from sex; that cultural construction alone should be studied.

Some reacted to this proposition. Errington (1990), for example, makes the distinction between 'sex', 'Sex', and 'gender'. By 'Sex' she refers to a particular social construct of human bodies. The term 'sex' by contrast refers to the physical nature of human bodies, while 'gender' refers to what different cultures make of sex. Given these distinctions she suggests that Yanagisako and Collier have conflated the meaning of sex and Sex. To disassociate gender from sex, that is from physical bodies, would lead to a confusion about what gender means and would simply reaffirm the distinction between nature and culture and the presumed hierarchical relations between them. Rather, the relation between sex and gender, biology and culture is interactive, the one not predetermining the other.

Yet if sex as a biological category is itself a product of western history, can it exist independently outside of a social matrix? Moore (1994) notes this, taking issue with both Yanagisako and Collier and with Errington. She argues that if the category sex does not exist independently of a social context we can only really speak of Sex in any given society. As is shown by historical studies as well as by ethnographic research (e.g. Strathern 1980; 1988; Wikan 1978), not all societies have two mutually exclusive sexual categories but they do have a model of Sex. Given this, the analytic distinction, as Moore and others note, between sex and gender is no longer clear.

This does not mean that we must necessarily do away with the analytical categories of sex and gender; rather we must explore them further, and examine how they define and encompass one another in different contexts and discourses. Anthropologists seem to be moving towards new ways of understanding peoples' views of themselves and their relations, towards what some would define as an anthropology of identity.

genealogies

Genealogies comprise verbal or diagrammatic representations of people's kin, and sometimes affinal, relationships. Their study, especially in relation to other aspects of kinship, has long been important in anthropology.

Interest in genealogies is most strongly associated with W.H.R.Rivers (e.g. 1914). In his fieldwork in the Torres Straits, in India, and in the Pacific, they provided him with both a ready means to understand the relationships between individuals and a means to work out the complexities of relationship terminology usage. The latter was important because of his belief in the conservative nature of relationship terminologies. He believed that embedded in their structures would be clues to the social organization of earlier times, and late in his life he also looked to such terminological structures for clues as to the connections between ethnic groups.

It is important to distinguish genealogical relationship from biological relationship. In anthropology, genealogies are always taken to indicate social relationships, which may or may not be truly biological. They may include, for example, presumed relatives, adoptive relatives, or even fictive relatives. Their extent is determined by what is culturally relevant, but they always include relatives on both sides of a given family; it should be possible to match one person's genealogy up with another to produce a 'map' of kin relationships which connect family to family. It is thus also important for a fieldworker to distinguish a person's genealogy from his or her pedigree. The latter is a subjective account provided by an informant and often emphasizes important kin relationships (such as descent from a unilineal ancestor) over other genealogical ties (Barnard and Good 1984). Thus, genealogies, as anthropologists usually understand the term, lie somewhere between the biological facts of reproduction (whose objective truth is anthropologically irrelevant) and indigenous statements of how individuals are related. The collection of genealogies both employs and helps to verify the truth of the latter.

There are a number of common problems in the collecting of genealogies. Informants 'collapse' them (forgetting unimportant ancestors), treat sibling relationships as genealogically equivalent (especially if they are terminologically equivalent), or claim ties which are not recognized by other members of the community. Where marriages are between close kin, the same person may legitimately be traced as a relative through more than one genealogical tie, and one of these ties (not always the closer) may be given

precedence. Widespread adoptions, fictive egocentric kin relationships (like godparenthood), or culturally-specific equivalents to 'kinship' (like namesake-equivalence or age-mate equivalence) may complicate things further. However, in spite of all this, anthropologists generally agree that there is something universal about the 'genealogical grid', which consists of all (or all culturally-significant) relationships through parenthood and marriage, whatever the specific meaning of parenthood and marriage in any given culture. Without the recognition of such a device, the comparative study of relationship terminologies would be impossible.

There is little doubt that genealogies are useful for understanding social structure, and also simply for getting to know the individuals among whom an ethnographer works. Almost invariably, genealogies are more important in the cultures which non-indigenous anthropologists study than in the cultures from which those anthropologists come.

general equilibrium theory

The motivation for general equilibrium theory is the belief that an economy can be understood only as a set of interrelated markets and that any change, for example in economic policy or in preferences, may affect the equilibrium on all markets. Moreover, the direct effects of a change which affects one market may well be outweighed by the indirect effects on other markets. To be successful as a tool for policy analysis and prediction, an economic model representing such an economy should reflect this interdependence. General equilibrium theory is the study of such economic models.

Walras (1874) is traditionally credited with the development of the first formal general equilibrium model, but there can be little doubt that many earlier economists had appreciated the importance of links between markets. The model of Walras was competitive, so that both firms and consumers treated prices as parametric when determining their behaviour, but relied on a linear production technology. Walras's

contribution was to formalize the concept of general equilibrium and to show that the formal model had as many equations as unknowns so that, potentially, it could have a well-defined solution. The model of Walras was developed in the German-language literature of the 1930s around the group of economists led by Menger in Vienna, culminating in Wald's (1936) proof that the model possessed an equilibrium when it satisfied the strong axiom of revealed preference. Essentially, this assumption restricts the consumption sector to act as if it were a single consumer.

Under more general assumptions, but still retaining competitive behaviour, the existence of equilibrium was established by Arrow and Debreu (1954) and McKenzie (1954). That an equilibrium exists under weak conditions can be judged as fairly remarkable and establishes the internal consistency of the model. What is more surprising is that the equilibrium also possesses properties of efficiency. As shown by Arrow (1951), the competitive equilibrium is Pareto optimal and any Pareto optimum can be decentralized as a competitive equilibrium. It has also been shown that the existence and efficiency properties apply in economies with an infinite number of goods (Bewley 1972) or with an infinite number of consumers (Aumann 1964). However, the efficiency properties do not apply when both the number of goods and consumers is infinite (Samuelson 1958). The latter case, which represents an economy that has an infinite future with some new consumers being born in each period and some old consumers reaching the end of their lives, is important in demonstrating that the competitive outcome is not always efficient. The Arrow-Debreu model of general equilibrium has been the basis of countless analyses in economics and has also formed the foundation for modern finance theory (Merton 1990).

When imperfect competition is introduced, the existence of equilibrium can be established only under strong assumptions. Existence results have been given by Negishi (1960–1), Arrow and Hahn (1971) and Cornwall (1977), but these have been undermined by the demonstration of Roberts and Sonnenschein (1977) that economies could be constructed that failed to satisfy the required assumptions. Despite this, imperfectly competitive general equilibrium economies can still be valuable in the analysis of policy (Myles 1989). In the late 1980s a development in the theory of general equilibrium has been the introduction of increasing returns to scale and the proof of the existence of equilibrium when firms operate bounded-loss pricing rules (Cornet 1988).

genetic aspects of mental illness

The idea that 'insanity' may be hereditary is an ancient one, but it was not until the twentieth century that this began to be explored in a systematic and scientific fashion. Two major developments at the beginning of the century allowed this to occur. The first was the rediscovery in 1900 of Mendel's laws of inheritance (which had lain ignored since their publication in 1866) signalling the birth of a new science which in 1909 Bateson called *genetics.* The second was the elaboration of a workable and widely accepted system of classification of mental disorders largely based upon the work of the German psychopathologist Emile Kraepelin. However, from the outset, attempting to reconcile observations on the patterns of inheritance of common mental disorders within families with Mendelian laws proved to be problematic. Although some comparatively uncommon disorders with neuropsychiatric manifestations such as Huntington's disease

clearly showed dominant inheritance (50 per cent of the offspring of affected parents showing the disorder), and some forms of mental retardation showed a recessive pattern (25 per cent of the offspring affected when both parents are unaffected 'carriers'), the more severe forms of common mental disorders such as schizophrenia or manic depressive illness showed a more complicated picture. Both of these disorders appeared to be more common in the relatives of sufferers than in the population at large, but there appeared to be no regular pattern within families and many patients had no known family history at all.

The question therefore arose as to whether schizophrenia and manic depression ran in families simply because of some shared environmental effects rather than through genetic mechanisms. The answer came by researchers capitalizing on an 'experiment of nature' afforded by twins. Identical, or monozygotic (MZ), twins have all of their genes in common as well as sharing a common environment. Non-identical, or dizygotic (DZ), twins share, on average, 50 per cent of their genes and it is assumed, particularly when they are the same sex, that they share environments to roughly the same extent as MZ twins. Therefore if MZ twins are more often concordant (i.e. both affected) than DZ twins for a disorder such as schizophrenia or manic depression, this should indicate that genetic factors are playing a part. The use of twins as a tool for studying the genetics of human behaviour was first suggested by Francis Galton in the late nineteenth century, but the methodologies were not fully worked out until the 1920s and 1930s by Luxenberger and other psychiatrists of the Munich school. These researchers were able to demonstrate higher MZ than DZ concordance for schizophrenia, manic depression and a variety of other conditions. Tragically, the mounting evidence that genes played a part in mental disorders was taken up by the Nazi party and used to support its eugenics policies, eventually leading to sufferers from mental disorder being sterilized or exterminated under the naïve assumption that this would lead to the eradication of such disorders in future generations. Although this was both morally repugnant and scientifically idiotic, Nazi eugenics received some support from the medical profession. The eventual outcome after the Second World War was the eradication, not of mental illness, but of modern psychiatric genetics in the country of its birth. A popular mistrust of genetics generally and psychiatric genetics in particular still persists in Germany.

Fortunately researchers elsewhere, such as the British psychiatrist Eliot Slater and the Dane, Eric Strömgren, both of whom had been Visiting Fellows in Munich, kept psychiatric genetics alive. Twin studies focusing mainly on schizophrenia but also on manic depression, alcoholism and neurotic disorders were carried out deriving their samples from registers. These provided a method of systematic ascertainment (or sampling) overcoming the potential bias of earlier twin studies which tended to oversample the most conspicuous pairs, that is, those who are both monozygotic and concordant. For the first time researchers also attempted to overcome diagnostic biases by using explicit criteria and keeping investigators 'blind fold' to zygosity and the diagnosis in the other member of the twin pair.

The other method developed to separate the effects of genes and family environment was to study those removed from their biological parents early in life by fostering or adoption. The first adoption study of schizophrenia was carried out by Heston in the late 1960s who found strikingly that five out of forty-seven individuals adopted away from

their schizophrenic mothers themselves developed schizophrenia. This contrasted with none of fifty control adoptees. Publication of other adoption study results quickly followed, and particularly influential was the work of Kety and others who matched up psychiatric and adoption registers in Denmark and in a series of studies confirmed that the vital factor in predisposing to schizophrenia was having a biological rather than an adoptive relative with the disorder. This took place at a time when 'anti-psychiatrists' such as R.D.Laing were attacking orthodox medical approaches towards schizophrenia, and others, such as T.Szasz, were claiming that the whole concept of mental illness was mythical. Kety was thus provoked to remark that if 'schizophrenia is a myth, then it is a myth with a strong genetic basis'.

Studies using twin and/or adoption methods have gone on to demonstrate a probable genetic contribution to a wide range of disorders, including both typical bipolar manic depression (episodes of mania and depression) and unipolar depression (episodes of depression alone) as well as certain types of anxiety disorders and, more controversially, alcoholism and even antisocial personality and criminality. Research in psychiatric genetics is attempting to move beyond merely demonstrating that a genetic contribution exists to using statistical model fitting techniques to estimate how much of the variance in liability to a disorder can be attributed to genes, to shared family environment and to individual specific environments. Model fitting techniques have also been used to try and differentiate between modes of transmission such as single gene, polygenic (many genes of small effect) or oligogenic (a handful of genes). Such statistical approaches provide a preliminary for the next stage, which is to attempt to localize and eventually identify the genes responsible for mental disorders using the methods of genetic linkage or association. Such methods have been dramatically successful in rarer single-gene neuropsychiatric disorders such as Huntington's disease and familial early onset Alzheimer dementia. The task is much more difficult with more common and complex disorders such as schizophrenia because of uncertainties over the mode of transmission. Nevertheless advances in molecular genetics have provided a nearly complete linkage map of the human genome (i.e. the twenty-three pairs of chromosomes carrying genetic material) which means that it is now feasible to search for markers linked to even complex traits. It seems likely therefore that genes for the more severe types of common inherited mental disorders will be localized within the foreseeable future.

genetics and behaviour

In the late nineteenth century, Sir Francis Galton collected information on accomplishments, physical traits and occupational status of members of families and began the correlational approach to behaviour genetics. In agreement with the prevailing sentiment of the British establishment, the finding that these characters aggregated in families was used as a biological justification for the social class structure of the time and even for the predominance of the British Empire. Kamin (1974) points out that similar reasoning by American psychologists responsible for the administration of intelligence tests to immigrants to the USA led to Congressional passage of the Immigration Act 1924 which restricted immigration to the USA from southern and eastern Europe. Thus over the past hundred years the issues involved in the relationship between genetics and behaviour have had serious political ramifications.

R.A.Fisher (1918) reconciled particulate Mendelian transmission genetics with the

continously varying phenorypes that interested the biometricians. This paper led to the variance-analysis approach to familial data on continuously varying traits, in particular, behavioural characters. The idea is that overall phenotypic variance, P, can be partitioned into contributions due to variation in gene action, G, those due to environmental variation, E, and interactions between genes and environment. Later, animal breeders termed the ratio of G to P the 'heritability' of the trait. The sense in which animal breeders used heritability was as an index of amenability to selective breeding. Of course, this is inappropriate in the context of human behaviour, and in this context it unfortunately developed the connotation of an index of biological determination and refractivity to environmental intervention.

The use of heritability in situations where experimental controls are lacking has been criticized by geneticists, who prefer to think in terms of the 'norm of reaction'. The norm of reaction for a given genotype is the graph of the phenotype against the environment. It emphasizes the dependence of gene action on the particular environment; a genotype that performs better than another in one environment may do worse in a second. An example is the human genetic disease phenylketonuria, PKU, in which sufferers accumulate toxic concentrations of phenylalanine resulting in extreme mental retardation. Under a diet that restricts intake of phenylalanine from birth, normal mental function occurs. The norm of reaction approach informs us that even if the heritability of IQ were 100 per cent, this would say nothing about its potential for environmental manipulation.

Fisher's approach to the genetics of continuous variation produces expected values for correlations between relatives of all degrees which can then be compared to observed correlations and heritability estimated. In principle the most powerful data of this kind use adoptions and, in particular, identical twins reared apart. Such twins are extremely difficult to find and unfortunately the largest sample, that published by Burt in his analysis of the heritability of IQ, has been shown to be fraudulent. The remaining samples of this kind normally suffer from non-randomness in the adoption procedure. Nevertheless, until about 1970 the estimates obtained using data that included Burt's produced the widely accepted statistic that genes accounted for about 80 per cent of variation in IQ.

Wright's (1934) method of path analysis became the predominant one for estimating heritability. In 1974 this method produced an estimate of genetic heritability of 67 per cent. Path-analytic treatments make allowances for assortative mating and for the transmission of environments within families, that is, cultural transmission. Estimates by Rice *et al.* (1980) and Rao *et al.* (1982) suggest that genetic and cultural transmission each account for about one-third of the variance in IQ. As with Fisher's variance analysis, the path-analysis approach is based on linear models of determination and has been criticized for that reason. Among the other criticisms are that most adoptions are not random, that the increase in mean IQ of adoptive children over that of their biological parents is ignored, and that the estimates of genetic and cultural heritability depend on how the environment is defined and its transmission modelled.

It has frequently been claimed that a high heritability of a trait within a group makes it more likely that average differences between groups, for example, races, are genetic. This is false since heritability is strictly a within-group measure strongly dependent on the range of environments in which it is measured.

In studies of the distribution of human behaviours within families, where the database is not as large as that used for IQ and where the trait in question is a clinically defined disorder, the twin method and the method of adoptions have been widely used. In the twin method the fraction of identical (monozygous or MZ) twin pairs in which both members are affected is compared to that in fraternal (dizygous or DZ) twin pairs. A significant margin in favour of the former is taken as evidence of genetic aetiology. Numerous studies of these concordance rates for criminality, neuroses, homosexuality, drinking habits, affective disorders such as manic depression, and schizophrenia have generally shown greater agreement among MZ than DZ twins. In these studies the twins are usually not reared apart and the role of special environmental influences, especially on MZ twins, cannot be discounted. Other problems such as the mode of ascertainment of the proband, heterogeneity in syndrome definition and variation among the concordance rates in different studies also raise doubts about the efficacy of the twin method.

In the adoption method, the incidence of a trait in the adoptive relatives of an affected adoptee is compared with that in the biological relatives. If the latter is higher than the former the inference is usually drawn that there is some genetic aetiology to the disease. Adoption studies of behavioural disorders from among those mentioned above have generally produced higher agreements between biological than between adoptive relatives. Again the interpretation of a genetic basis for the behavioural abnormality must be viewed with circumspection, since truly random adoption is extremely rare and frequently adoption occurs relatively late in childhood. In none of the behavioural disorders mentioned above has any biochemically distinguishable genetic variant been identified, although research directed at the role of variation in properties of catecholamine and indole metabolism still continues.

The evolution of social behaviour has provided something of a puzzle to natural historians since Darwin. This field of study was subsumed under ethology and behavioural ecology, and until the mid-1970s was relatively immune to the developments in evolutionary population genetics by Fisher, Wright (1934) and Haldane (1932; 1955). The year 1975 saw the publication of E.O.Wilson's book *Sociobiology* in which he not only stressed that social behaviours were similar across the animal kingdom from termites to humans, but also claimed that these behaviours were genetically determined. Ethology and much of behavioural ecology were then subsumed under a new name, 'sociobiology'.

J.B.S.Haldane had speculated in 1932 as to how alarm calls in birds might have evolved genetically but concluded that a simple genetic basis for the evolution of self-sacrifice might only apply to the social insects. In 1955 he foreshadowed sociobiology by asking for how many cousins should one's self-sacrifice be equivalent to that for a brother. These speculations were formalized by Hamilton (1964), who modelled the evolution of a gene, one allele of which conferred altruistic behaviour on its carrier. Altruism here means that the fitness of the altruistic individuals is reduced by their performance of a behaviour which increases the fitness of others in the population. Hamilton arrived at conditions on the degree of relatedness between the donor and recipient of the behaviour that would enable altruistic genotypes to increase in the population. The condition is usually stated in the form $\beta r > \gamma$ where β and γ measure the gain in fitness to recipients and loss in fitness to donors, and r is a coefficient of

relatedness. Hamilton noted that in the haplodiploid insects like the hymenoptera his measure of relatedness between sisters is higher than for any other relationship. Since the above inequality is then easier to satisfy than in species where both sexes are diploid, this could explain on a simple genetic basis the evolution in the social hymenoptera of the social caste system with sterile workers. This theory of the evolution of the kin-directed behaviours is now called 'kin selection'.

Hamilton's theoretical analysis was made using a mathematical approximation that allows the allele frequency of the altruistic variant, the altruistic gene frequency, to play the central role. With this approximation the mathematics gives the impression that it is possible to add fitness contributions from all relatives affected by the altruism to produce the inclusive fitness of the allele. It has been shown that inclusive fitness is an unnecessary concept and that the theory of kin selection can be developed in terms of classical population genetic models with frequency-dependent Darwinian fitness differences. Hamilton's formulation contains many assumptions, but when these are removed his theory remains qualitatively true: the closer is the degree of the relatedness between the donor and recipient of an individually disadvantageous behaviour (controlled by a single gene), the easier it is for that behaviour to evolve.

In *Sociobiology* E.O.Wilson extrapolated from Hamilton's theory to posit that the evolution of social behaviour throughout the animal kingdom including *Homo sapiens* has followed these rules of kin selection. Of course this position ignores the general criticism that none of the social behaviours discussed have been shown to have a genetic basis and are certainly not under simple genetic control. Although many behavioural ecologists took Wilson's position in the years immediately following the publication of his book, the difficulty of empirical measurement of relatedness, and fitness gains and losses, as well as technical criticism by population geneticists, have had a moderating effect. Kinship still plays a central role in behavioural ecology, but the explanatory limitations of the simple kin selection theory are now more widely appreciated.

In *Homo sapiens* the position of sociobiology is to minimize the role of learning and cultural transmission of social behaviours. In particular, the human sociobiologists have taken the position that such phenomena as aggression, incest taboos, sex-differentiated behaviours, sexual preferences, conformity and spite have largely genetic antecedents. There is clear political danger in acceptance of this assertion that such human behaviours have a genetic basis. We have the precedent of the politics of IQ based on erroneous inferences drawn from data of dubious quality. Sociobiology adopts a position of pan selectionism in which the terms adaptive and genetic are interchangeable. Cultural transmission, under which the properties of evolution are obviously different from those under genetic transmission, is ignored. Clearly sociobiology tried to claim too much: 'Sooner or later, political science, law, economics, psychology, psychiatry and anthropology will all be branches of sociobiology' (Trivers in *Time,* 1 August 1977). Fortunately, we are all biologists enough to tell the tail from the dog.

geographical information systems

Geographical information systems (GIS) are integrated computer systems for the capture, storage, updating, manipulation, analysis and display of all forms of geographically referenced information. Although this definition stresses software, any successful application of GIS must also include appropriate data, hardware, and personnel. The basic concepts underlying GIS were developed by geographers during the 1960s, but use of complete systems grew dramatically during the 1980s as the costs of computer power fell and workstation computing became commonplace. GIS find application in all academic disciplines in which the element of location in space is important, such as geography, archaeology, land use planning, natural resource management and demography. In industry and commerce they are used in retailing, the public utilities, and local government. Because of the ubiquity of spatial location, it can be argued that GIS

will become one of the largest of all computer applications.

GIS differ from standard database management systems and from computer mapping systems in one important respect. This is their ability to answer intrinsically spatial questions such as 'How many people live within 500m of this road?' If GIS were simply 'maps' in computers, they could not answer this type of question. Instead, they consist of a database describing, or modelling, selected aspects of the geography of the real world. Although systems vary, typically this is achieved by holding a number of 'layers', each of which describes some thematically related aspect of the geography, together with computer software tools to link these layers in various ways. Within each layer various approaches are used to describe the geography of interest. It is necessary to know where each feature of interest is, what it is, and how it relates to other, similar, features. Some systems use a *vector* approach in which each feature is described by lines (vectors), each made up of a series of point locations, which are coded into tables in the database. What the feature consists of and how it relates to other features are similarly coded. Vector systems grew out of older mapping programs and are usually used in socioeconomic applications. Other systems make use of a *raster* model to describe each layer. In this the earth's surface is subdivided into small, regular, elements (typically grid squares), and the presence or absence of the feature, or its numerical value, is recorded and stored for every single element. Raster systems grew out of image processing programmes and find most use in resource management and other environmental applications. Most commercial systems implement both of these approaches to varying degrees and provide software to enable conversion between them. Finally, some systems are totally *object oriented,* dispensing with the concept of a single layer and recording instead all the properties of each feature of interest as a single entity. In each case, the volume of data required is likely to be large, and the initial capture and organization of these data forms a major part of the total cost of implementing a GIS.

geography

Geography is an academic discipline whose main concerns are describing and understanding areal differentiation in the distribution of various phenomena across the earth's surface. It focuses on the nature and interrelationships of three concepts—environment, space and place. This has produced a threefold division of the discipline into physical geography, human geography and regional geography respectively, with the first two containing separate systematic subfields.

As an academic discipline, with a major presence in universities and similar institutions, geography is about a century old. It was introduced, in Germany and elsewhere, to provide a source of ordered information about places; such material was of particular value to the civil services and (especially in times of conflict) armed forces of

imperial nations (Taylor 1985). Geography was also promoted as an important subject in school education in a number of countries, to advance both 'world knowledge' as an end in itself and the ideological bases of national views.

With the development of universities as research as well as teaching institutions, geographers sought coherent frameworks for their discipline which would establish them as the equal of scholars in the burgeoning sciences and social sciences. This stimulated a number of proposed definitions of the discipline's content and methods, of which the most notable in the English language were probably Hartshorne's *The Nature of Geography* (1939) and Wooldridge and East's (1951) *The Spirit and Purpose of Geography.* Such prospectuses were largely rejected in the 1960s and thereafter, although the ideas of some of the discipline's founders—notably Paul Vidal de la Blache (Buttimer 1971)—continue to attract interest and support.

For a variety of reasons, some related to the subject's strengths in the relevant country's school system (as in the UK), geography became a very popular university discipline in many countries: to cater for the student demand, large numbers of academic staff were appointed. From the 1960s on these adopted the ethos of the modern university, with its emphasis on research as the base on which degree-level teaching is founded and with research achievement as the major criterion for career advancement. This provided the context for a rapid growth of research output and much experimentation with alternative epistemologies, methodologies and subject matters. Thus geography is an extremely broadly based discipline, and most academic departments of geography are catholic in their subject matter coverage (Johnston, 1991a).

Subject matter and divisions

Areal differentiation of the contents of the earth's surface covers both the physical environment and the many human modifications to that environment created in the struggle to exist and to enhance material and cultural living standards. The various approaches to the study of such areal differentiation have loosely coalesced around three major themes.

Environment

The 'natural' environment of an area comprises the land surface itself (relatively few geographers study the oceans), the hydrology of the water bodies on that surface, the fauna and flora which occupy it, the soils which form a thin layer on its surface, and the atmosphere immediately above. All are linked in complex environmental systems—the flora of an area, for example, influence the climate above it and the formation and erosion of soils beneath. Many physical geographers focus their attention on one aspect of the environmental complex only, however, in their detailed search for understanding its genesis and continual change (K.J.Gregory 1985).

These separate focuses are represented by the various subdivisions of physical geography, with most individuals claiming to specialize in one subdivision only rather than to be generalist physical geographers. Most of the subdivisions are linked to allied

disciplines, to which some physical geographers claim more affinity than they do to the rest of their 'home' subject (Johnston 1991b).

Of the subdivisions, the largest is *geomorphology*, the study of landforms at a variety of spatial scales, and the processes which create them. Many geomorphologists pay particular attention to the role of water as a landscape-forming agent, thereby creating close ties with hydrology: others, especially those interested in the longer-term processes of landform genesis, have closer affinities with geologists, whereas those concerned with soils have links with pedologists. Much smaller groupings are those of *climatologists* (with links to meteorology) and *biogeographers*, who focus much more on plants than on animals and so associate with ecologists and botanists rather than zoologists. Although most physical geographers work within just one of these subdisciplinary groupings, there is increasing recognition of the importance of studying the interactions among the various components of the environmental complex—not least because of the impacts of each on the others, as illustrated by the current concern with rapid environmental change.

There has also been increased recognition of the impact of human occupancy of the earth's surface, soils and atmosphere on the operation of geomorphological, hydrological, biological and atmospheric processes, with consequences for the ability of the environment to sustain human life in the long term if not the short term (Turner *et al.* 1990). This is leading to more team research which combines the various specialist skills.

Whereas the study of the physical environment is almost exclusively the preserve of physical geographers, there has always been some interest in the physical landscape among human geographers, mainly those concerned with the analysis of landscapes as part of the milieu of human life. To some, interpretation of physical landscapes is central to human endeavour, and so popular conceptions of how 'the earth works' (of the hydrological cycle, for example) are important sources of geographical understanding. To others, the concept of nature itself is a social construction and so interpretations of the physical world are part of the ideological superstructure of society.

Space

While physical geographers have focused their studies on the so-called 'natural' environment, the main concern of human geographers has been the occupation and use of that resource base. Land use was a major topic of interest for several decades, at a variety of scales (e.g. the difference between urban and rural areas at one scale and the agricultural use of different fields at another). Much of this work was descriptive, chronicling what was done where, with little attempt at explanation other than through the relationship with the physical environment.

In the late 1950s, the influence of pioneering geographical work in Scandinavia and of spatially oriented studies by economists and sociologists led to the promotion of an alternative perspective for human geography which focused on the spatial organization of human activity on the earth's surface. The goal was a scientific reconstruction of the discipline, whose rationale was to be the identification of the laws of both individual spatial behaviour and spatial patterns in the distributions of their artefacts. Distance is an impediment to human behaviour, because it takes time and costs money to cross space in the movement of goods, people and ideas. In order to minimize such costs, interaction

patterns are organized on distance-minimizing principles, producing spatial organizations (of, for example, the pattern of settlements in an area) which ensure least-effort solutions. Human geography was thus presented as a 'discipline in distance', with distance the key concept that distinguished it from the other social sciences: spatial concepts were presented as the discipline's theoretical base (Johnston 1991a).

Numerous attempts were made in the 1960s and 1970s to codify this approach to human geography and its subject matter, and to identify its fundamental concepts. The most successful and widely cited was produced by Haggett (Haggett 1965; Haggett *et al.* 1978), who divided the discipline's subject matter into: point patterns (such as farm buildings in an agricultural area); hierarchical point patterns (such as shopping centres of various sizes and importance within an urban region); line patterns (notably transport networks); movement patterns (such as the flows along networks, whether of people, goods or information); surfaces of variations in a continuous phenomenon (such as maps of the density of population and of the value of land within an urban area); and diffusions over space (such as the spread of a disease along a network, across a surface and/or down a hierarchy). To this can be added territories, the divisions of continuous space into discrete entities—whether nation-states, ghettos, or personal spaces within an open-plan office. Others sought the fundamental basic concepts of a spatial discipline: for Nystuen (1963) these primitives were direction, distance, connectiveness and, perhaps, boundary.

The goal was to identify spatial laws, which involved adopting a scientific methodology based on the quantitative evaluation of hypotheses. Thus both physical and human geographers switched from describing patterns cartographically to analysing them statistically and (to a lesser extent) modelling them mathematically. The discipline developed a very strong quantitative core in the 1970s, with a great deal of hope that it could attain scientific respectability through its methods and the generality of its finding (Harvey 1969).

This new geography of the 1960s and 1970s was introduced at a time of rapid growth in the study of geography in universities, especially in most of the English-speaking world. The 'quantitative and theoretical revolutionaries' could therefore promote their view of the discipline in a context of expansion: the large number of available staff positions and research studentships enabled them to 'take over' the discipline very substantially, and to advance their particular view of what geography studies, and how.

Rapid expansion of a discipline, most of whose practitioners were strong adherents to the research ethos of the modern university, meant that these new ideas were applied to a wide range of subject matters. Prior to the 1960s, human geography had some important subdisciplines (such as historical geography), but to a considerable extent it was divided by areal rather than sectoral interests (i.e. it was divided according to practitioners' interests in the geography of certain parts of the world). This changed rapidly, and the incipient sectoral divisions soon achieved predominance over disciplinary practice.

Those subdisciplines are cross-cutting, in a variety of ways. Four of the most enduring reflect links with the main other social sciences: economic geography with economics; social geography with sociology; political geography with political science; and cultural geography with anthropology. Practitioners of the first two were more numerous in the 1960s and 1970s. The others grew more slowly, and later; the link with anthropology has been much stronger in the USA than elsewhere. There were also subdivisions of the

subdivisions, notably the several distinct areas of specialization within economic geography: industrial geography, agricultural geography, transport geography, retail geography, and the geography of service industries, for example.

A second set of subdivisions involved the separation of urban geography from rural geography (with the latter largely distinct from agricultural geography). Urban geography was the focus of much of the early quantitative and theoretical work, and became heavily populated in the 1960s and 1970s. It had its own subdivisions: urban social geographers who studied residential segregation in cities, for example, were largely separate from those who studied economic aspects of urban places, (such as the group influenced by the ideas encapsulated in 'central place theory' regarding the spatial organization of shopping centres and of the spatial behaviour of individuals who visited them).

By the mid-1970s, therefore, human geographers interested in the study of spatial organization were divided into a number of somewhat independent subgroups, each with strong links outside the discipline. Their commonality within geography was defined by the procedures that they used rather than the subjects that they studied, and by their emphasis on distance as a key concept. (There were other, smaller, subdisciplines, such as medical geography.) This work continues, and the strength of the subdivisions is marked by the proliferation of academic journals concentrating on the specialist parts of geography (Johnston 1994).

During the 1970s, however, unease about the discipline's fragmentation grew and a number of geographers, many of a Marxian persuasion, argued that society should be studied as a whole (Harvey 1973). Areal differentiation is an outcome of the processes of uneven development which involve social, political and cultural as well as economic factors, so important theoretical work by Harvey (1982) and others promoted the study of spatial organization as both an outcome of and a constraint to processes of capitalist development and underdevelopment. This stimulated a very different orientation to the study of space, and much debate (see, e.g. Sayer 1992) over whether spatial patterns are contingent outcomes of social, economic, political and other processes or whether, as those who promoted the 'geography as a discipline in distance' approach contended, distance is a determinant influence on human behaviour. Work in the Marxian and realist moulds was concerned with elucidating the general processes of uneven development rather than with statistically analysing patterns of development and of spatial behaviour within them. This led to conflict over epistemology and methodology.

The growth of interest in what has variously been termed a political economy approach, a structural approach, and a realist approach to uneven development, in its many forms and at a variety of spatial scales, took place during a period of very rapid change in the societies being studied (Peet and Thrift, 1989). During the 1980s, in particular, there was very substantial economic restructuring which involved considerable rewriting of the map of uneven development; there were major cultural shifts, too, with the promotion of 'enterprise societies' and attacks on welfare states; and nationalism grew as a response to several forms of political hegemony in many parts of the world. This rapidly changing scene attracted much geographical attention.

Place

As already noted, geography emerged as an academic discipline to promote knowledge
about places; it involved the collection, collation and presentation of information about
different parts of the world. As it matured, so its practitioners perceived the need for
more sophisticated methods of working than mere collecting, mapping and cataloguing:
they wanted an intellectual framework which allowed them to advance knowledge as well
as order information.

Various attempts were made to produce such a framework. Considerable support went
in the early decades of the twentieth century to *environmental determinism,* in which the
basic argument was that human occupancy of and action upon any part of the earth is
determined by its physical character. This was widely discredited by the 1930s, and
replaced by *regional geography,* whose rationale was description of the individual
character of each region (a defined area of the earth's surface, delimited according to
certain criteria). Individual geographers thus became regional geographers of defined
areas—usually of continental or sub-continental scale—and their major publishing
activities involved describing those areas, often in substantial regional texts.

Regional geography was methodologically weak—over the defining criteria, the means
of determining regional boundaries, and descriptive protocols, for example. Much of it
was strongly influenced by the environmental determinism paradigm; most regional
geographies started with descriptions of the area's physical environment, as the context
for, if not determinant of, the patterns of human occupancy there. To some, regional
geography was an advanced art-form, whose goal was accurate description of a place's
character.

This approach was becoming increasingly discredited by the 1960s, among
geographers attracted to the spatial science paradigm of 'geography as a discipline in
distance'. It was condemned as little more than mere fact gathering and presentation in
woolly analytical frameworks—unscientific and not respectable for an academic
discipline. It languished with the rapid growth in the number of geographers adhering to
other approaches, and has never recovered, although there are still some who identify
themselves as regional geographers and see their discipline's task as describing and
analysing the world's complex mosaic of places to wide audiences. (Those audiences
were for long schoolchildren, taught by the graduates of university departments. Few
geography graduates become teachers now, and few school syllabuses emphasize
regional geography.)

The study of place was thus very substantially devalued within geography, but it
revived—albeit in a different form—from the 1970s on. This renewed interest was
initially promoted by those—many of them historical or cultural geographers—who were
disenchanted with the spatial science paradigm and its search for laws of patterns and
behaviour. Such laws, they argued, denied individual free will and thereby denigrated
human individuality, culture and decision making (D.Gregory 1978; Ley and Samuels
1978). Similar criticisms were addressed at some of the early Marxian work on uneven
development, which implied that capitalist processes were structural determinants within
which individuals had few degrees of freedom to act. Neither approach—spatial science

or structural Marxism—corresponded with some geographers' perceptions of the empirical world, within which there was much cultural, social and political variation that could not be ascribed to economic determinants, however important material concerns were as impulses to human behaviour.

This alternative view, which became associated with the cultural turn in other social sciences in the 1980s, was linked to several contemporary intellectual developments. The rise of feminism, for example, not only demonstrated the oppression of women in most societies and the male dominance in the construction of academic disciplines such as geography (Rose 1992), but also showed that different groups within society have different perspectives on it: there is no one predominant view, though one may dominate academic and other discourse (D.Gregory 1994). Similarly, reactions to imperialism—cultural as well as economic and political—showed how the map of the world and the construction of understandings of its various parts was structured by the ideological goals of hegemonic groups. The growth of ecological and environmental movements, promoting different interpretations of the relationships between peoples and environments, similarly advanced an alternative conception of how society could be organized.

Difference rather than similarity became a focus of geographical scholarship, therefore. Place was central to this because of its role as a constraining factor in cultural development and of the importance of place to constructions of the world. People learn who and what they are in places, and they develop notions of identity (their 'sense of place') within places. Places are milieux, created by people in the context of their perceptions of nature there, and in which people are created as new residents and socialized into the dominant construction of that place and what it is to be part of it. An important component of the construction of a place identity involves its opposition to that which it is not: part of the definition of what characterises one place is its difference from others—mainly but not only its neighbours, and so people in places develop images of other places and their residents.

Much of this work on place is not antithetic to that on the processes of uneven development, therefore, although it is largely opposed to spatial science. It enriches the political economy approach by stressing the importance of people and their positions within society as strong influences on what they do—whether in very local contexts or as world politicians. The understanding of the spatial organization of the world and its many component parts requires full appreciation of the nature of the people who are continually reconstructing that world, in the context of their place-contingent views of both their place in the world and those of all others.

Approaches and methods

Geography has been characterized since the Second World War by three main approaches to its subject matter and, within human geography at least, considerable debate about their merits and disadvantages (Johnston 1991a). In addition, there has been debate and dispute within each approach over the relative advantages and disadvantages of different methods.

As both physical and human geography moved from a descriptive to an analytical stance during the 1950s and 1960s, so the attractions of the positivist approach to science, with its emphasis on testable hypotheses leading to the formulation of laws and the derivation of theories, became seductive. This approach was strongly associated with quantification, and the belief that statistical regularities were the proof of the existence of theoretically suggested empirical cause-and-effect relationships. Thus measurement and the statistical manipulation of data replaced verbal and cartographic description as the dominant geographical procedures.

As with any discipline seeking to adopt and adapt procedures developed elsewhere, this switch to the positivist epistemology involved much trial and error analytical work and many relatively trivial empirical analyses. By the late 1960s, however, some geographers realized that statistical procedures developed in other disciplines could not readily be adopted for geographical work because of the particular features of spatial data sets: spatial autocorrelation was recognised as an impediment to drawing causal inferences from many analyses of spatial data, and led to sophisticated development of spatial statistical methods. (Many geographers ignored these important arguments, however, and either disregarded the problem or assumed that it didn't matter.) Geographers have thus been involved in the burgeoning work on the development of applicable statistical procedures for the analysis of spatial patterns and spatial behaviours. Whether they have identified many strong regularities indicative of the operation of causal laws is doubted by some, however: many intriguing findings have been reported, but such is the complexity of the physical and human contexts being studied that it is very difficult to disentangle the general from the locally particular. Many of the hopes of the early disciples of the 'quantitative and theoretical revolution' have been dashed on the difficulties of successfully testing meaningful hypotheses. They have provided much sophisticated description of the world, however, even if they have provided few clues to how it works (Harvey 1989).

The measurement-based approach to the discipline involved much experimentation and innovation in means of collecting data in the field, both in the operation of processes in the physical environment and from individuals pursuing their spatial behaviours. These have been assisted by major revolutions in the technology of data capture, storage, display and analysis, in many of which geographers have played important pioneering roles. The first of these involved the field of *remote sensing,* which is usually, but far from exclusively, associated with imaging the earth from space (Curran 1987). Vast quantities of data are produced by satellites and other airborne carriers of imaging equipment, and geographers have been at the forefront of developing means of interpreting the information provided through large-memory computing devices—in order to portray detailed environmental variations over time and space. Remote sensing has provided not only much new material with which to analyse the earth but also many technical puzzles over how to transform and interpret that material in the pursuit of research goals.

Most geographical data refer to two- (if not three-) dimensional contexts. These have traditionally been represented in map form, but developments since the late 1970s in *geographical information systems* (GIS) have very significantly advanced the ability to store, visualize and analyse such spatial data in computer systems. The presentation of

data and their analysis, through the ability to layer data sets on to each other (for example, rainfall observations at individual sites on to topographic maps), substantially enhances both the ability to suggest hypotheses for empirical testing and the conduct of those tests (Maguire *et al.* 1991).

Reaction to the deterministic cast of much of the argument for a spatial science of human behaviour led to interest among human geographers in what became widely known as humanistic geography, which emphasized individuality and difference rather than conformity and similarity. A range of epistemologies was investigated—including phenomenology, idealism, existentialism, and pragmatism (Jackson and Smith 1984) but the main impact of this work was its opposition to the alternative paradigm being promoted, especially in the early 1970s.

The emphasis in this humanistic work was on interpretation—both interpretation of the world by those acting in it and interpretation of their actions and the outcomes (landscapes, for example) by geographers. The enterprise was strongly hermeneutic in flavour, therefore. Geographers were exploring the interpretations behind people's actions, often, especially in the case of historical work, through the study of texts, both written and visual (i.e. maps, works of art, and landscapes), and then transmitting those interpretations to their own readers. This resulted, apart from the programmatic essays advancing the humanistic cause and attacking the positivist approach, in a range of essays on a diversity of topics.

Key to much of this hermeneutic work was language, since most understandings are transmitted through words, which are very imperfect because of their openness to differences in interpretation (Barnes and Duncan 1992). The importance of language and difference in the later post-modernism project has been important to the advance of this approach to geography, with its very strong antagonism to notions of grand theory and totalizing explanation. Place is central to this, in part because much learning of language and its nuances is place-bound.

The methods of humanistic geography are those of interpretation, therefore, which raises a variety of issues relating to sources of information and their treatment. As already indicated, some of those sources are texts which have to be interpreted in the context of their production (the language and ideology of the time and place, for example); others involve collecting material directly from the individuals concerned, which means that much research is ethnographic in character, with all the associated ethical and other concerns.

The implicit determinism of the positivist approach to human geography, and the voluntarism of its humanistic counter, were together the focus of a third major approach to the discipline, also initiated in the early 1970s. As indicated above, much of this work was Marxist-inspired and represented the economic imperatives of capitalist processes as underpinning the ever-changing map of uneven development. Some of the early work was overly determinist also, however, and portrayed a set of socio-spatial processes which individuals and collectivities were largely impotent to combat. Within a few years, however, the structural thinking of the approach was being married with the arguments for difference and individuality within a humanistic one (Kobayashi and Mackenzie 1989). This generated a rich and sophisticated framework for appreciating how space, place and nature are constructed and reconstructed by knowing individuals, acting within

the limits of their own appreciation and constrained by the structural imperatives of the capitalist mode of production. The perspectives of post-modernism have added to this, emphasizing difference and individuality (Soja 1989).

As with the humanistic approach, the structuralist/ realist relies very heavily on textual interpretation. It is not as antagonistic to the use of quantitative data, however, though little of it involves sophisticated analysis of such material. More importantly, its goal is to identify not only specific causes but also general processes which underpin them, and which cannot be apprehended empirically. In some ways, this is similar to approaches to the understanding of large-scale environmental systems whose empirical complexities, which reflect locally contingent factors, obscure the underlying fundamental physical laws and their interactions.

Applying geography

Geography was invented as an academic discipline because of its potential applied value in promoting world-understanding. Since then, the importance of an applied stance has varied, in part at least because of the demands made on the discipline, and indeed on academia in general. Taylor (1985), for example, has argued that states, which provide much of universities' income, are more likely to press for applied work—with academics meeting the needs of society—in periods of economic recession than in times of relative prosperity, when pure research can flourish: in some societies, of course, such as those of the USSR and eastern Europe between 1945 and 1989, the practice of geography, and all other academic disciplines, was almost entirely determined by the demands of the state apparatus.

The applied value of geography was appreciated in the Second World War with the ability of geographers to provide information about other countries; their cartographic and photogrammetric skills were widely employed in intelligence work. From the 1950s on, the role of geographical work, first in data collection and later in their analysis and use in prescription, as in the preparation of town and regional plans, was increasingly recognized and some of the technical developments since (as in GIS) have been oriented to such practical applications: indeed, some argue that one of the geographer's most important roles is to add value to data, which can then be 'sold' to spatial decision makers (Rhind 1989).

The growing concern over environmental issues—local, regional, national and global—has attracted much attention. Geographers' stress on both the processes that operate in the physical environment and the impact of human activity on those processes and their outcomes has generated much work, in the conduct of environmental impact assessments, for example.

Much of this applied work sees geographers applying the methods and goals of the positivist approach in seeking solutions to a variety of perceived problems: they are involved in the engineering of social futures on the basis of their scientific understanding. This technocratic view has been challenged by other geographers, who see such work as promoting the status quo within society, thereby maintaining its many inequalities and injustices and sustaining both the capitalist mode of production and the state apparatus

whose goal is to promote and legitimize what is perceived as an unjust system. For such critics, there are other applied roles for geographers, in promoting awareness of the nature of the changing world in which we live (both self-awareness and awareness of others) and in advancing the cause of emancipation, whereby people are enabled to obtain control over society and steer it towards their own ends. Each is a political goal and is contested by adherents to other views: all involve geography as the servant of particular political causes, although some would deny this and argue that theirs is a neutral, scientific role within constraints set by a society—of which, of course, the geographers are members.

Summary

Geography is a large and vibrant academic discipline, with roots in the sciences, the social sciences and the humanities. It comprises a number of overlapping communities of researchers and teachers, all seeking to advance our understanding of environment, space and place in a great variety of ways.

The differences among these communities in their approaches to the discipline ensure continued debate about the relative merits of alternative perspectives. Alongside those, however, there is a great deal of substantial research and scholarly activity which is advancing our appreciation of how the physical environment is constructed and operated, of how human life is organized spatially, and of how places are created as the milieux within which most people are socialized.

gerontology, social

Gerontology is the scientific study of biological, psychological and sociocultural aspects of the ageing process. Social gerontology is concerned only with its socio-logical-anthropological component. Although public interest in old age commonly stems from the association of ageing with social problems, such considerations will be excluded from this discussion.

Social gerontology emerged in the late 1950s and has become established as a recognized subject of study and research in academic institutes throughout the world, especially in the USA. The conceptual approaches and methodologies applied in this field reflect a wide gamut of theoretical frameworks and techniques. Nonetheless, three core issues in the study of behavioural phenomena in later life can be identified: the relative importance in ageing of universal human processes and specific cultural factors; the dialectic between stability and change in later life; questions concerning the place of the elderly in a social structure, and in the symbolic worlds of both aged and non-aged persons.

First, the quest for universal, generic characteristics of ageing has taken several theoretical forms. Some anthropologists have imputed common needs and aspirations to all old people, such as the desire for a prolonged life and dignified death, and they have tried to identify general role features, such as a shift from active participation in economic production to sedentary advisory roles. Similarly, 'disengagement theory' states that there is a gradual process of mutual disengagement between aged persons and their society in all cultures. Critics have cited cross-cultural and cross-sectional data to show that there have been a variety of context-bound, behavioural responses to old age. It has also been argued that patterns of active behaviour among elderly people, as well as manifestations of retreatism and inertia, are conditioned by environmental constraints and cultural configurations. However, some psychologists with a similar universalist bias have maintained that the process of ageing is governed by an increased concentration on the inner self, and especially on a retrospective life review.

Second, ageing is a dynamic process of concurrent transformations in various spheres of life. In a complex, changing society, where life transitions are generally equated with social mobility and progress within a given career opportunity structure, the changes associated with old age engender a paradoxical perception of later life. In a social

structure which allocates statuses and prestige according to mastery of information, control of wealth and command of physical resources and mental faculties, aged persons are conceived of as a stagnant, marginal social category. This stereotype persists, in spite of the growing numbers of elderly people whose life expectancy is increasing and whose functioning capacities are improving relative to previous generations. Such incongruity between social definition and personal experience generates ambivalence and ambiguity. In the experience of the temporal universe of old people, long-term planning becomes problematic, if not impossible. The past is recalled selectively, and is mined in order to construct a meaningful present. The struggle of old people for continuity in identity is often expressed through their review and reinterpretation of life histories, as well as through their reorganization of social relationships and systems of meaning. Temporal asynchrony and disorganization of this kind usually does not exist in so-called simple societies, where the position of old people accurately reflects the balance between their control of valuable resources and their diminishing ability to protect their interests. In some economically 'hand-to-mouth' preliterate societies, an aged person whose presence becomes a burden may be abandoned or ritually killed. In agricultural societies, however, knowledge and spiritual powers are attributed to aged people. Elders have social and ritual roles entailing a honourable place in society.

Third, social roles are often associated with age categories. Passage through a series of age grades represents an important organizing principle of social life in most simple societies. In modern societies, age is less significant than occupational specialization. Yet the phases of 'childhood' and 'old age' are, by definition, social categories circumscribed by age norms, which are decisive in shaping individuals' social identities. The very fact that age alone is enough to define 'the old' reflects the disappearance of the normally decisive occupational and other roles and values, which in turn generates negative images and stereotypes of elderly people. This phenomenon has led a number of scholars to consider the potential development of subcultural or counter-cultural social units made up exclusively of the aged. Research on such groups, mainly in age-homogeneous communities, day centres and residential settings, shows that in many cases a new alternative system of social relationships and symbolic meanings is developed to supersede those of the prior, stigmatizing and alienating social milieu.

Social gerontology is currently in a transitional phase. Many aspects of ageing can be analysed and explained by other disciplines, but the growing reservoir of data and theory on old age encourages social research into such specific issues as the politics of ageing, ageing and the law, and the existential problems connected with old age. Much research is also directed to aged persons as a social problem and the object of public social concern. The central issues have been defined, but there is as yet no adequate theoretical treatment of them.

globalization

The development of the world economy has a long history, dating from at least the sixteenth century, and is associated with the economic and imperial expansionism of the great powers. By globalization we refer to a more advanced stage of this process of development. The global economy is one in which all aspects of the economy—raw materials, labour information and transportation, finance, distribution, marketing—are integrated or interdependent on a global scale (Carnoy *et al.* 1993). Moreover, they are so on an almost instantaneous basis. By global economy, 'we mean an economy that works as a unit in real time on a planetary basis' (Castells 1994:21). The forces of globalization thereby tend to erode the integrity and autonomy of national economies.

Newly emerging and consolidating global corporations are the driving force behind these developments. Where multinational corporations in the past operated across a number of national economies, economic globalization now requires corporate interests to treat the world as a single entity, competing in all major markets simultaneously, rather than sequentially. This may involve the marketing of global products or world brands such as Coca Cola, McDonald's or Kodak (Levitt 1983). In most cases, however, global competitiveness will require more complex and differentiated strategies. Managing in a borderless world in fact necessitates the segmentation of corporate organization and marketing according to transnational regions, notably those of Europe, North America and the Far East (Ohmae 1990). Some global corporations describe their approach, more precisely, as one of global localization, recognizing the continuing significance of geographical difference and heterogeneity. The globalization of economies is more accurately seen in terms of an emergence of global-local nexus.

Globalization has been made possible through the establishment of worldwide information and communication networks. New telecommunication and computer networks are overcoming the barriers of time and space, allowing corporate and financial interests to operate on a twenty-four-hour basis across the planet. The inauguration of information superhighways promises to further extend this compression of our spatial and temporal worlds (Harvey 1989). Global media are also part of this complex pattern of transborder information flows. Using new satellite and cable systems, channels like CNN and MTV have begun to create truly global television markets and audiences (though here too, there is growing realization of the need to be sensitive to local differences).

Instantaneous and ubiquitous communication gives substance to Marshall McLuhan's idea, first put forward in the 1960s, that the world is becoming a global village.

As national economic spaces become less functional in the global context, cities and city-regions are assuming a new role as the basing points in the spatial organization of international business. Cities are consequently compelled to attract and accommodate the key functions of the global economy (services, finance, communications, etc.). This results in inter-urban competition across national borders, leading to the formation of a new international urban hierarchy. Cities must aim to become key hubs in the new global networks. Metropolitan centres such as New York, Tokyo and London may be described as truly 'world cities' (Friedmann 1986) or 'global cities' (Sassen 1991), the command centres in the global economy. Competition among second-level global cities involves the struggle to achieve ascendancy within particular zones of the world. This competition also requires cities to distinguish their assets and endowments through strategies of place marketing and differentiation: in a context of increasing mobility, the particularities of place become a salient factor in the global positioning of cities (Behrman and Rondinelli 1992). As well as attracting global investors and tourists, cities are also the destinations of migrant and refugee populations from across the world. Global cities are also microcosms in which to observe the growing dualism between the world's rich and poor and the encounter of global cultures.

We should consider what globalization means for the world's cultures. Is there a global culture? What might we mean by this (Featherstone 1990)? In the case of commercial culture (film and television, popular music, etc.), there are certainly aspirations towards creating a unitary, worldwide market. Global media corporations, such as Time Warner, Sony and News Corporation, are thinking in terms of global products and global audiences. This is possible only with certain kinds of programming, however, and for the most part global media interests operate in terms of transnational media spaces (e.g. the 'Eurovision' region; the 'Asian' region served by Murdoch's Star TV). At the same time, there are contrary tendencies, towards the proliferation of national and also regional (e.g. Basque, Gaelic) media. This may be seen in terms of the (re)assertion of cultural difference and distinction in the face of globalising tendencies. Again it is the relation between the global and local that is significant (Sreberny-Mohammadi 1991). The globalization of the media should be understood, then, in terms of the construction of a complex new map of transnational, national and subnational cultural spaces.

Cultural globalization—associated with flows of media and communication, but also with flows of migrants, refugees and tourists—has brought to the fore questions of cultural identity. For some, the proliferation of shared or common cultural references across the world evokes cosmopolitan ideals. There is the sense that cultural encounters across frontiers can create new and productive kinds of cultural fusion and hybridity (Rushdie 1991). Where some see cosmopolitan complexities, others perceive (and oppose) cultural homogenization and the erosion of cultural specificity. Globalization is also linked, then, to the revalidation of particularistic cultures and identities. Across the world, there are those who respond to global upheaval by returning to their 'roots', by reclaiming what they see as their ethnic and national homelands, by recovering the certainties of religious tradition and fundamentals. Globalization pulls cultures in different, contradictory, and often conflictual, ways. It is about the deterritorialization of

culture, but it also involves cultural reterritorialization. It is about the increasing mobility of culture, but also about new cultural fixities.

We may see globalization in terms of the new possibilities opened up by global communications, global travel and global products. Or, alternatively, we may consider it from the perspective of those for whom it represents unwelcome destabilization and disorientation. To some extent, this difference may be a matter of who will gain from global change and who will lose or be marginalized. Globalization occurs as a contradictory and uneven process, involving new kinds of polarization (economic, social and cultural) at a range of geographical scales. The encounter and possible confrontation of social and cultural values is an inevitable consequence. We have a global economy and global culture: we do not, however, have global political institutions that could mediate this encounter and confrontation.

gold standard

A gold standard represents a style of monetary organization in which gold fulfils the functions of a central money (i.e. numeraire). Gold becomes the main store and measure of value as well as a central medium of exchange. In this respect, a gold standard is a metallist rule for organizing money since a metal, in this case gold (but historically various other metals have been used), becomes the foundation for managing a money supply. Although it has fallen out of use as a means of managing national money after the Second World War, historically this type of monetary system has prevailed at both the national level (practised most widely as a form of organizing national money from the 1850s up to the First World War) and international level (especially 1880–1914 and 1947–71). National and international monetary organization is now founded on a fiat standard where the value and acceptability of monies does not derive from the intrinsic value of some commodity like metal, but derives instead from the decrees of governments.

Although there has not been a uniform means of practising a gold standard, such an organization of money at the national level has traditionally been oriented around several central practices or rules. First, money is defined in terms of some fixed quantity of gold. For example, in 1879 a US dollar was defined as 23.22 grains of fine gold. Since one fine ounce of gold equalled 480 grains, then one fine ounce of gold was equal to 20.67 dollars. All denominations of money are defined in either multiples or fractions of the central unit of account (in this case the dollar), hence all money has a clear correspondence to some quantity of gold. Traditionally, these domestic par values have been kept stable over time. Second, individuals enjoy perfect interconvertibility between gold money and non-gold-monies (principally notes) at rates which are legally determined. In this respect, notes ultimately represent claims on gold itself. Hence both notes and gold become widely acceptable as means of clearing debts and making purchases to unlimited amounts (i.e. acquire legal tender). This has become known as the practice of domestic convertibility.

Third, coins made of metals other than gold can circulate only as token money (small-denomination coin). These coins normally possess an intrinsic value which is significantly below their nominal value. Fourth, monetary authorities stand ready to coin all gold brought to them (usually for a slight charge referred to as seigniorage) and stand ready to convert notes into gold at legally specified rates. Fifth, individuals can hold gold in whatever form they choose (bullion or coin) and can freely import and export gold in whatever amounts they desire. Sixth, international reserves are held principally in gold. Hence gold becomes the principal reserve and vehicle currency between nations which are practising gold standards. Finally, monetary authorities institute a rule which links the creation of money (i.e. growth in the money supply) to the stock of gold. In this latter respect, a gold standard (or any metallist-standard for that matter) represents a classic

'rule' governing the management of a money supply.

At the international level, the currencies of nations practising gold standards become interchangeable at fixed exchange rates which derive from the respective domestic pars. Gold fulfils the function of an international numeraire in that it becomes the foundation for international transactions. Historically, such an international regime has both arisen spontaneously (as in the period 1880–1914) and been intentionally orchestrated by economically powerful nations (as the USA did in creating the Bretton Woods regime 1944–71).

Advocates of such rules have traditionally supported gold standards as means of escaping the unstable and inflationary effects of discretionary fiat monetary regimes where growth in the money supply is free from binding rules and subject to the whims of monetary and political elites. This support for a gold standard is all the more enhanced by a preference for fixed over flexible exchange rates. Critics of such rules have argued that a gold standard is too rigid to allow for the management of the business cycle (i.e. it does not allow authorities the luxury of inflating out of depression), and that developments in the money supply are overly dependent on the vagaries of mining. The case against a gold standard is enhanced by a preference for flexible over fixed exchange rates.

governance

Governance is a term that applies to the exercise of power in a variety of institutional contexts, the object of which is to direct, control and regulate activities in the interests of people as citizens, voters and workers. For political scientists, governance refers to the process of political management which embraces the normative basis of political authority, the style in which public affairs are conducted, and the management of public resources. It is a broader concept than government, which is specifically concerned with the role of political authorities in maintaining social order within a defined territory and the exercise of executive power. Three terms are central to most definitions of

governance: accountability, which denotes the effectiveness with which the governed can exercise influence over their governors; legitimacy, which is concerned with the right of the state to exercise power over its citizens, and the extent to which those powers are perceived to be rightly exercised; and transparency, which is founded on the existence of mechanisms for ensuring public access to decision making.

Governance is not restricted to the formal political realm; it also operates at the level of the firm or the community. Corporate governance is concerned with the processes by which corporate entities are governed, namely the exercise of power over the direction of the enterprise and mechanisms for ensuring executive acountability and the regulation of corporate actions. In more localized contexts, governance can refer to endogenously evolved sets of rules or authority structures within particular communities which play a role in resource management and in the maintenance of social order.

From the early 1990s the concept of governance attracted considerable interest from international aid donors concerned with political and administrative obstacles to successful economic development in the Third World. The analysis of the World Bank and other donors centres on a perceived crisis of governance stemming from self-interest, corruption and a loss of political legitimacy, which are associated with weak and undemocratic states. This concern with governance has also raised questions about the appropriate role of international institutions such as the World Bank and the United Nations in global economic and political management, and the nature of their mandate.

In the developed world, there are two main sources of pressure shaping ideas about governance. One stems from problems of governability manifest in a breakdown of law and order and despondency with formal political institutions which raises concerns about the manner in which the institutions of government should interact with citizens. A second set of influences derive from a neo-liberal political agenda which advocates a diminished role for the state and transforming it from a provider of services to a purchaser and regulator.

Proposals for bringing about improved governance centre on mechanisms to promote the decentralization of power and responsibility, and to increase consultation and participation in decision making. In developing countries, proposals for better governance often imply a return to liberal democratic politics and controls on executive power, along with civil service reform and bureaucratic reorientation with a view to increasing the accountability, legitimacy and effectiveness of public management. This is challenged by an alternative view which suggests that strong government is essential for political stability which in turn provides the best guarantee of successful development.

government

The study of government lies at the heart of political science, but there is little unanimity within the discipline as to how it should be studied or as to the types or forms that exist. Indeed, the term itself has a multiplicity of distinct, if related, meanings. Only an overview of the confusion and controversy can be given here.

Following Finer (1974) we can discern four different meanings of the term government. First, government refers to the process of governing, that is, the authoritative exercise of power. Second, the term can be used to refer to the existence of that process, to a condition of ordered rule. Third, the government often means the people who fill the positions of authority in a society or institution, that is, the offices of government. Finally, the term may refer to the manner, method or system of government in a society, that is, to the structure and arrangement of the offices of government and the relationship between the government and the governed.

The existence of some institution of sovereign government is a distinguishing feature of the state. The study of such sovereign governments has been a major preoccupation of political scientists. But not all governments are sovereign; any institution, such as a trade union, a church group or a political party, which has a formal system of offices endowed with the authority to make binding decisions for that organization, can be said to have a government. Equally, government (in the sense of ordered rule) may exist in the absence of the state. A number of anthropological studies have revealed the existence of primitive societies in which conflict is resolved by various social processes without resort to the coercive powers of a formalized state. Indeed, in any society there are many social situations (such as a bus or theatre queue) where potential conflict over an allocative decision is avoided by a non-coercive social process.

Sovereign government in advanced societies is normally regarded as consisting of three distinct sets of offices, each set having a particular role: First, the role of the *legislature* is to make the law. Second, the *executive* (also sometimes confusingly referred to as the government) is responsible for the implementation of the law and in most advanced polities has come to play a predominant role in the formulation of proposals for new laws. Third, the *judiciary,* meanwhile, is responsible for the interpretation of the law and its application in individual cases.

Classification schemes

The precise arrangement of the offices of government varies from state to state. Ever since Aristotle, the study of government attempted to classify the varieties of governments according to different types. The purpose of such classification exercises has varied, and has included both a desire to make normative statements about the best type of government and positive statements concerning the behavioural implications of

different governmental structures. But all the classification exercises have in common an attempt to produce conceptual categories that make it possible to make meaningful generalizations about government in the face of a bewildering variation in the ways governments are organized.

Classifications of government are legion, yet some common threads can be discerned. Classifications have tended to concentrate on two criteria: the arrangement of offices, which is more narrow in conception; and the relationship between the government and the governed.

The first criterion has produced two classification schemes which are in wide currency among political scientists, particularly among students of democratic government. The first classification scheme is based on the relationship between the executive and the legislature. In a parliamentary system, the executive is dependent for its continuance in office upon maintaining the support of the legislature. Members of the executive are commonly also members of the legislature. While a prime minister may be the most powerful member of the executive, important decisions within the executive are usually made collectively by a group of ministers. In a presidential system, the executive is independent of the legislature. Members of the executive are not normally also members of the legislature, while the ultimate source of decision-making authority within the executive lies with one person—the president. The second classification scheme concentrates on the distribution of power between different levels of government. In a unitary state, all authority to make laws is vested in one supreme legislature whose jurisdiction covers the whole country. While it may permit local legislatures to exist, they do so only on the sufferance of the main legislature. In a federal state, there exist local legislatures which have at least a measure of guaranteed autonomous decision-making authority. Both forms of government can be distinguished from a confederation, where a group of states combine for certain purposes but with each state retaining its sovereignty.

Classifications based on the second criterion—the relationship between the government and the governed—have commonly concentrated on the extent to which governments attempts to achieve their aims by coercion of their citizens rather than persuasion, and on the extent to which limits are placed on the legitimate authority of government. The precise formulation of classification schemes based on this criterion varies widely, but not uncommonly a distinction is drawn between, at one extreme, liberal democratic government and, at the other, totalitarian governments. Under liberal democratic government, government is seen as primarily responsive to the wishes of society, and clear limitations are placed upon its ability to coerce society or to mould it in any particular way. Totalitarian governments have few limits placed upon them and are seen as instruments whereby society may be changed.

New approaches

The study of government has changed considerably since the Second World War. Historically, the study of government grew out of the study of constitutional law. It was characterized by a concentration on the formal institutions of government and upon constitutional provisions, while individual countries tended to be studied in isolation

rather than in comparative framework. However, under the influence of the behavioural revolution, scholars have paid increasing attention to how governments actually operate, to institutions outside the formal apparatus of the state but which play a vital role in its operation (such as political parties and pressure groups), and to explicitly comparative study. Particularly influential in the development of comparative study have been approaches derived from systems theory, especially structural-functionalism. These approaches have attempted to develop a conceptual language, based upon the functions that are performed within any society, that could be applied to the study of government in any country, including developing as well as advanced societies.

group dynamics

Group dynamics was originally the term used, from the 1930s to the early 1950s, to characterize the study of changes in group life by Kurt Lewin and his followers. Gradually, however, the term lost its restricted reference and came to be more or less synonymous with the study of small groups. This broader, second sense will be used here.

A small group consists of from three to about thirty persons, every one of whom can recognize and react to every other as a distinct individual. The members are likely to

manifest: perception of group membership; sustained interaction; shared group goals; affective relations; and norms internal to the group, which may be partially organized around a set of roles. Those are the most commonly invoked defining criteria of small social groups.

According to Hare (1976), by the end of the first decade of the twentieth century about twenty social scientific articles on small groups had appeared and many of the subsequent concerns of small group research had been identified. In 1898 Triplett reported laboratory and field experiments on the effect of the group on individual performance. Within the next half-dozen years, Cooley wrote about the importance of the primary group; Simmel discussed some of the consequences of group size; Taylor, the apostle of scientific management techniques, started to examine pressures on individuals to conform to group norms regarding productivity; Terman studied group leaders and leadership. From about 1920 onwards, the rate of publication started to increase. The 1930s saw the appearance of three classic lines of research: the work of Lewin *et al.* on different styles of leadership; the best-known parts of the programme of research at the Western Electric Company's Hawthorne plant, together with Mayo's selective and misleading popularization of their findings; reports by Moreno and others of sociometric techniques designed to represent choices, preferences or patterns of affect in a group.

By the late 1930s, the developing study of group processes was seen, in the USA at any rate, as part of the defence of conventional democratic practices in the face of authoritarian threats, and high hopes and expectations continued through the 1940s to the heyday of small group research, the 1950s and early 1960s. During that period Bales produced his category system for the relatively detailed description of group interaction processes, the sensitivity or experiential group appeared on the scene, and those not preoccupied with experiential groups increasingly studied laboratory experimental ones. In the 1970s the quantity of work did not abate but some of the sense of excitement and enthusiasm did. Mainly via laboratory experiments, a variety of delimited issues, often refinements of earlier topics, provided successive focuses for attention. These included co-operation and competition; aspects of group cohesion; leadership styles; social influence processes, including a new interest in minority influence; group decision making and group polarization; personal space and density; and interpersonal attraction. Increasing methodological sophistication was claimed and the absence of major theoretical advances bemoaned.

Initially the study of group dynamics, in the original, narrow sense, was held to offer answers to a number of democracy's problems (Zander 1979), but eventually the most tangible legacies of the group dynamics movement were the spawning of, first, group-centred training groups and, then, individual-centred existential groups. This shift from a concern with the world's problems to the soothing of personal anxieties perhaps was symptomatic of the failure of the study of small groups to fulfil its potential (Steiner 1974). All too often, narrow questions were studied with increasingly restricted methods, leading, at best, to mini-theories which failed to sustain interest in the issues. Some of the reasons for this reflect North American experimental social psychology more generally. But the nature of the groups studied must have been a contributing factor. In practice, the study of small groups came to be concerned not with families, friends, committees and the multitude of social groups that mediate between individual and society but with small

collectivities of student strangers meeting for no more than an hour; it is likely that a majority of groups studied manifested few, if any, of the defining properties of actual social groups. In an analogy with nonsense syllables, Fraser and Foster (1984) dubbed those small collectivities 'nonsense groups'. In the late 1970s and early 1980s, the field seemed to be in the doldrums.

However, the study of small groups has been showing some signs of revival. Academic social psychologists not only have begun to generate new theoretical ideas for the investigation of standard topics in the laboratory (e.g. Turner 1991) but also are revealing more concern for the contexts in which naturally occurring groups function (Levine and Moreland 1990) and for some selected real-world issues, including crowding, the operation of social support, and relations between groups (Baron *et al.* 1992). These real-world issues, however, are still frequently studied in social psychologists' laboratories rather than in the worlds of lay people. But a major change in the study of small groups appears to be that the dominance of social psychology is no longer as marked as it had been since the 1940s. The study of real social groups is increasingly being tackled by researchers from other domains, such as family researchers and, especially, researchers in the area of organizations and work, where many of the newer developments regarding leadership, group effectiveness and the like are now located. It remains to be seen whether these changes in emphases will be sufficient finally to create a study of group dynamics which can adequately illuminate the major part played by small social groups in the relations between individuals and the societies they live in.

groups

The concept group features prominently in sociology and anthropology because of their interest in social relationships that are habitual, institutionalized and relatively enduring. Group has been used in many different ways, but it commonly refers to a plurality of individuals bounded by some principle of recruitment and by a set of membership rights and obligations. Everyone fulfilling the recruitment criteria is a member of the group and occupies a specific status in the group, and every group member automatically has the rights and discharges the obligations of membership. Groups are, in turn, the main elements of the social structure.

Critics of such a conceptualization of groups stress the fact that the notion of a society as consisting of permanent discrete groups is not a generalization from the observable social processes, but is either the analyst's model or a model that the members themselves have of their own society. When the object of the analysis is not to explain actual social processes, but rather the actors' cultural notions, or the cognitive structure of a given society, then the group can be defined simply in terms of the ideology of group membership.

Reference group (Merton and Kitt 1950) refers to a collection of persons with which individuals identify, or which they use as a point of reference for their aspirations; it is a typical example of a group as a notional entity. But the manifestation of groups in actual interactional situations cannot be assumed to follow automatically from their existence as notional phenomena. Instead, the interactions of specific individuals are seen to derive from their decisions about which of their numerous statuses or group memberships, or which of their interpersonal relationships, they wish to activate. In turn, these decisions cannot be generalized in terms of permanent groups but only in terms of cultural preferences. The distinction between the cognitive model of the society as consisting of permanent discrete groups, and the actual social processes in which the society's members are involved, led to the conceptual distinction between the social structure and social organization (Firth 1951) and to the development of network analysis. It also led to a more rigorous conceptualization of a group and to the analytical distinction between social groups and social categories.

A *social category* is a collection of individuals grouped conceptually because of some shared socially relevant features or characteristics (age, sex, occupation, religious beliefs, common ancestry, mutual genealogical relationship, and so on). A *social group* consists of individuals who interact in an interconnected set of roles (such as economic, political, ritual, occupational). While membership of a specific category usually defines eligibility for membership in a group, taking up group membership is not an automatic process; whether eligible persons will activate their group membership depends on many contingent factors other than belonging to the category. Depending on the nature of the interaction of its members, it is customary to distinguish *primary* groups whose members interact face to face (for example, a household or family) from *secondary* groups, all of

whose members do not necessarily interact directly and personally with one another (for example occupational or political groups). Some groups have the character of corporations in that they control a body of property or estate which may be either material (such as land or capital equipment) or immaterial (such as skills, privileges, ritual names, titles). Ownership of this property is held by the group as a single entity, and all its members acquire certain rights in the joint property. In consequence, corporate groups typically exhibit greater continuity than non-corporate groups: they retain their identity as groups over time although their personnel changes.

At the other extreme is an action group or task group. It consists of individuals who assemble in some organized fashion to perform jointly a specific task. Action groups have only a limited existence in time, and they dissolve once the task for which they organized themselves has been completed. What distinguishes most groups from a task group and other units like crowds, or gatherings whose existence is also temporary, is their more or less permanent existence deriving from the fact that their members interact recurrently and that they have a more or less enduring internal organization and discreteness, though these characteristics may be variously defined and stressed by different analysts.

H

Habermas, Jürgen (1929–)

Jürgen Habermas has been the most prolific and influential representative of the second generation of the Frankfurt School. He has not only continued the theoretical tradition of his teachers Adorno and Horkheimer and his friend Marcuse, but also significantly departed from classical critical theory and made many important contributions to contemporary philosophy and social theory. In particular, he has opened critical theory to a dialogue with other philosophies and social theories such as the hermeneutics of Gadamer, systems theory and structural functionalism, empirical social sciences, analytic and linguistic philosophy, and theories of cognitive and moral development. He has been synthesizing these influences into a theory of communicative action, which presents the foundation and framework of a social theory that builds on the tradition of Marx, Weber and classical critical theory, but also criticizes his predecessors and breaks new theoretical ground.

Habermas was born on 18 June 1929 in Düsseldorf, and grew up in Gummersbach, Germany. His father was head of the Bureau of Industry and Trade, and his grandfather was a minister and director of the local seminary. He experienced the rise and defeat of fascism, and was politicized by the Nuremberg trials and documentary films of the concentration camps shown after the war. Habermas began his university studies in Göttingen in 1949 and finished a dissertation of *Das Absolute und die Geschichte* in 1954. In the 1950s, Habermas studied—and was strongly influenced by—Lukács's *History and Class Consciousness* and Adorno and Horkheimer's *Dialectic of Enlightenment* which he first read in 1955. He studied the young Marx and the young Hegelians with Karl Löwith, one of Germany's great scholars and teachers.

Habermas resolved to work with Adorno and Horkheimer because he believed that they were establishing a dialectical and critical theory of society from within a creative and innovative Marxist tradition. He thus went to Frankfurt and continued his studies in the Institute for Social Research. In this context, he wrote his first major book *Strukturwandel der Offentlichkeit* (1962). Combining historical and empirical research with the theoretical framework of critical theory, Habermas traced the historical rise and decline of what he called the 'bourgeois public sphere' and its replacement by the mass media, technocratic administration and societal depoliticization. This influential work continues to animate discussion concerning problems of representative democracy in contemporary capitalist-societies and the need for more participatory, democratic and

egalitarian spheres of sociopolitical discussion and debate.

In the 1960s, Habermas taught at the universities of Heidelberg (1961–4) and Frankfurt (1964–71). At this time he also became more interested in politics and with others in 1961 published *Student und Politik,* which called for university reforms, and *Protestbewegung und Hochschulreform* (1969), which continued his concern with university reform and also criticized what he saw as the excesses of the German student movement in the 1960s. Habermas was also engaged in intense theoretical work during this period. His *Theorie und Praxis* appeared in 1963 (*Theory and Practice,* 1973), which contained theoretical papers on major classical and contemporary social and political theorists, as well as anticipations of his own theoretical position; *Zur Logik der Sozialwissenschaften* in 1967 contained a detailed and critical summary of contemporary debates in the logic of the social sciences; *Erkenntnis und Interesse* in 1968 (*Knowledge and Human Interests,* 1971) traced the development of epistemology and critical social theory from Kant to the present; and several collections of essays: *Technik und Wissenschaft als Ideologie* (1968); *Arbeit-Erkenntnis-Fort-schritt* (1970); and *Philosophische-politische Profile* (1971).

During the 1970s Habermas intensified his studies of the social sciences and began restructuring critical theory as communication theory. Key stages of this enterprise are contained in a collection of studies written with Niklas Luhmann, *Theorie der Gesellschaft oder Sozialtechnologie* (1971); *Legitimationsprobleme im Spätkapitalismus* (1973); *Zur Rekonstruktion des Historischen Materialismus* (1976); and essays collected in several other books. In these works, Habermas sharpened his critique of classical Marxism and his critical theory predecessors. He attempted to develop his own reconstruction of historical materialism, a critical theory of society, and a philosophical theory rooted in analyses of communicative action. During much of this period, since 1971, Habermas was director of the Max Planck Institute in Starnberg where he involved himself in various research projects and was in close touch with developments in the social sciences. After a series of disputes with students and colleagues, he resigned in 1982 and returned to Frankfurt where he is now Professor of Philosophy and Sociology.

In 1981, Habermas published his two-volume magnum opus, *Theorie des kommunikatwen Handelns.* This impressive work of historical scholarship and theoretical construction appraises the legacies of Marx, Durkheim, Weber, Lukács and western Marxism, including critical theory, and criticizes their tendencies towards theoretical reductionism and their failure to develop an adequate theory of communicative action and rationality. Habermas also contributes his own analysis of the importance of communicative action and rationality for contemporary social theory. The book points both to his continuity with the first generation of the Frankfurt School and his significant departures. *Theorie des kommunikatwen Handelns* also manifests Habermas's continued interest in the relationship between theory and practice with his discussion of new social movements. The concluding section is a testament to his interest in systematic social theory with a practical intent in his summation of the current status of critical theory. The work as a whole thus sums up Habermas's theoretical work in the 1970s and points to some issues and topics that constitute future projects.

Since 1981 Habermas has indeed continued to pursue development of a systematic articulation of his theory of communicative action in the fields of moral discourse and

legal and political discourse. *Moral Consciousness and Communicative Action* (1990) contains contributions towards developing a discourse ethics, while *Faktizitat und Gultung* (1992) articulates a discourse theory of law, democracy and rights. *Postmetaphysical Thinking* (1992) contains articles that articulate Habermas's attempts to reformulate modern theory in terms of a theory of communicative action that overcomes the metaphysical presuppositions of the philosophical tradition.

In addition, Habermas has published collections of essays commenting on contemporary political, cultural and historical events such as *The New Conservativism* (1989) and he edited a collection of *Observations on 'the spiritual situation of our time'* (1984). Perhaps his most controversial book, however, was *The Philosophical Discourse of Modernity* (1987) where Habermas launched an attack on French postmodern theory (especially Derrida and Foucault) and its predecessors (Nietzsche, Heidegger and Bataille). In this text and other essays of the period, Habermas defended the heritage of modernity, Enlightenment, and reason against the postmodern attacks.

A vast number of books and articles have appeared which defend or criticize Habermas, and he often responds to collections of books containing essays on his work, such as *Habermas and Modernity* (Berstein 1985). A collection of interviews *Autonomy and Solidarity* (Dews 1992) also provides answers to his critics and insights into his life and intellectual development. *The Past as Future* (1994) provides interviews in which Habermas expresses his views on contemporary political and intellectual developments. Habermas thus continues to be highly productive and controversial as he enters his sixth decade and he has emerged as one of the great intellectual figures of our time.

habitus

With a distinguished philosophical pedigree stretching from Hegel to Husserl, the notion

of the *habitus,* although used by Weber, Durkheim and Mauss, has established itself in the social science lexicon through the work of Pierre Bourdieu. It is central to Bourdieu's attempt to develop a sociology of human practice which, as he sees it, avoids the errors of both individualistic voluntarism and structuralist determinism.

In Bourdieu's usage it refers to an area of human being which is neither conscious nor unconscious, neither wholly social nor wholly individual. Residing in embodied individuals, it is the product of primary and secondary socialization, having its deepest roots in the earliest years of childhood. It is constituted in and by typically unreflexive processes of habituation and habit-formation.

The habitus is made up of classificatory schemes and practical dispositions, the two being intimately implicated in each other. Both are in a state of ongoing adjustment to the objective conditions of the social world of which the acting subject is a constituent. These schemes and dispositions, particularly the basic practical taxonomies in which classification and disposition most intimately coincide, are transposable from one social domain to another, as the logic of practice characteristic of a group or culture.

Embodiment is fundamental to the habitus. The body represents the point of view on which the most influential practical taxonomies—up:down, back:front, female:male, etc.—are centred. For Bourdieu the body, via the habitus, is a mnemonic device within and on which the foundations of culture are inscribed. The habitus is also constitutive of *hexis,* the socially and culturally distinctive physical style of being in the world (stance, movement, gesture).

Socially competent performances are, however, generated by the habitus without the actors necessarily appreciating what they are doing. Bourdieu is explicit that the habitus is not a set of rules governing behaviour, nor does it work through processes of conscious ratiocination. Rather, it is a framework within and out of which actors, to some extent thoughtlessly, improvise practices as a consequence of the interaction between their culturally specific dispositions and classificatory schema and the constraints, demands and opportunities of any specific social field or domain. A particular habitus will have origins in and most affinity with particular fields. It is in these encounters that internal subjectivity is ongoingly adjusted to the objective external world. This adjustment is one of the key processes by means of which the social world is reproduced.

In Bourdieu's own work this concept has been applied to a range of topics, from formal education, to cultural consumption to peasant marriage strategies. In its translation into anglophone sociology it seems to have been largely subsumed within an anthropologized model of culture. Although it can be criticized as overly dismissive of conscious decision making and residually deterministic, it offers an intriguing model of the social and cultural constitution of individual practice.

Hayek, Friedrich A. (1899–1993)

Recipient of the Nobel Prize in Economic Science (together with Gunnar Myrdal) in 1974, Friedrich August von Hayek was born in Vienna on 8 May 1899. He earned two doctorates at the University of Vienna—Dr jur. (1921) and Dr rer. pol. (1923)—and became Privatdozent in Political Economy in 1929. He was director of the Austrian Institute for Economic Research from 1927 to 1931. In 1931 he accepted an appointment at the University of London as Tooke Professor of Economic Science and Statistics. He was awarded a DSc degree by that institution in 1944. He remained at London until 1950, when he accepted a position at the University of Chicago. He returned to Europe in 1962 as Professor of Economic Policy at the University of Freiburg, and upon retirement from that institution in 1967 he accepted a position as honorary professor at the University of Salzburg, from which he received an honorary doctor's degree in 1974.

Hayek was instrumental in the founding of the Mont Pelerin Society in April 1947, a society whose aims were to contribute to the preservation and improvement of the free society. He served as president of the society for twelve years.

Hayek's broad scope of inquiry is reflected in his contributions to economic science. These include the theory of economic fluctuations; the pure theory of capital; the theory of economic planning under socialism and competitive capitalism; and the methodology of economics.

In addition to many articles, his theory of economic fluctuations was presented in two books: *Monetary Theory and the Trade Cycle* (1926 and 1933) and *Prices and Production* (1931). Beginning with Wicksell's theory of the 'cumulative process', Hayek expanded and modified Wicksell's theory and then proceeded to develop his own theory of economic fluctuations which included such elements as how changes in the quantity of money affect relative prices, rather than general price levels, as well as allocation of resources, especially between producer and consumer goods; the related disturbances in investment period and voluntary saving, as well as 'forced saving', bank credit and its effects on 'forced saving' and capital deepening; a model of the price mechanism and its operation in the context of fluctuations.

In 1941, Hayek published *The Pure Theory of Capital,* a treatise on capital theory. Among the topics treated and which represented a contribution to the theory of capital were the concept of 'intertemporal equilibrium'; physical productivity of investment; the phenomenon of natural growth; 'period of investment', the idea of the 'force of interest'; and finally, 'durable goods'.

In spite of his contributions to economic theory, Hayek was never accorded the recognition of his contemporary, J.M.Keynes, whose *General Theory* (1936) was accepted as the standard paradigm of economic fluctuations in economics. Also, the

Austrian theory of capital had fallen out of fashion by the time his *Pure Theory of Capital* appeared, and his work in this area was largely ignored. The later period of his career was devoted to political and social philosophy and methodology, the most popular publications on these being *The Road to Serfdom* (1944) and *The Counter-Revolution in Science* (1952).

health economics

Health economics is concerned with the analysis of health care inputs such as expenditure and employment, and an appraisal of their impact on that desired outcome, the health of society.

Clearly, many inputs may affect an individual's health. In a world of scarce resources it is necessary to ensure that these resources are used efficiently—that the cost of producing care and health is minimized and the benefits are maximized. At the individual

level, this can be modelled in a human capital framework (Grossman 1972). Grossman's model permits an exploration of the links between inputs (such as education, income, wealth, health care and nutrition) and their impact on health status; this work indicates that the relative importance of income and nutrition on health is greater than that of health care.

The evaluation of health care is seriously deficient. Cochrane (1971) has argued that most health care therapies in use have not been evaluated scientifically. By scientifically, he means the application of randomized controlled trials which administer the therapy under investigation to a randomly selected (experimental) group of patients, and a placebo or alternative therapy (a control) to another randomly selected group of patients. The difference, if any, between the therapeutic results for the experimental and control groups gives an indication of the relative impact of the therapies. Such results require replication to ensure validity, and such methods are noticeable by their relative absence (see Bunker *et al.* 1977).

Such clinical evaluation informs decision makers about the benefits of health care, but an economic component is needed to assess costs. The economist's role is to elicit the social opportunity costs of the alternative therapies, that is, the costs to all decision makers, both public (the government) and private (for example, individuals and their families). A guide to the application of such techniques and an appraisal of over a hundred case studies is provided by Drummond (1980; 1981).

The dominant (monopolist) role of the medical profession in the health care market-place has resulted in an investigation of physicians' capacity to create demand for their own and other people's services (Department of Health and Human Services 1981). This, together with the fact that third parties (governments and insurance companies, rather than patients or producers) usually pay for health care, has led to cost containment problems (McLachlan and Maynard 1982). To control such inflation, user charges (prices) can be introduced, a policy that has both costs and benefits (Maynard 1979; Newhouse *et al.* 1981); or more effective incentives must be devised to encourage producers (doctors) to economize, for example, through health maintenance organizations (Luft 1981).

The inefficient use of health care resources is clearly unethical; it deprives patients of care from which they could benefit. The aim of health economists is to generate information about the costs and benefits of alternative ways of achieving health and health goals. It is hoped that such information will improve the efficiency and equity of health care systems across the world.

health transition

Health transition means the changes over time in a society's health, as measured by both morbidity and mortality levels, and the determinants of those changes, especially the cultural, social or behavioural ones. Related terms include *mortality transition* and *epidemiologic* (or *epidemiological*) *transition.* Mortality transition was part of the vocabulary of *demographic transition* theory, which described the movement of societies from high birth and death rates to low ones, a phenomenon that was posited to consist of separate—although probably related—fertility and mortality transitions. The latter is now a worldwide phenomenon, and has been shown to have begun in England as early as the seventeenth century. *Epidemiologic transition* is due to Omran (1971) and refers not only to the decline in mortality but also to the change in the balance of disease and the causes of death as mortality declines. There is still controversy as to whether the level of sickness declines as death rates do, and some researchers (e.g. Riley 1990) deny that it does.

The term *health transition* was coined at a meeting organized by the Rockefeller Foundation at the Bellagio Conference Center in 1987. The intention was to include not only mortality but also morbidity, as well as indicating that the focus of interest would be improvements in health and well-being beyond what might be indicated merely by a reduction in illness. It was also intended that the field should embrace the determinants of morbidity and mortality decline, especially giving recognition to the growing body of evidence that this was determined not merely by the provision of modern medical services and rising levels of material well-being (as indicated by income, nutrition, housing, etc.) but by cultural, social and behavioural factors. The term met a need, as is testified by its increasing use and by its acceptance as an understood phrase by a range of journals and publishers. It is also included in the title of the journal, *Health Transition Review* (Caldwell and Santow, from 1991). In addition there are various collections of papers by writers on the subject (Caldwell and Santow 1989; Caldwell *et al.* 1990; Chen *et al.* 1993; Halstead *et al.* 1985).

The need to lay greater stress on social determinants of health has become ever clearer since the 1970s. In developed countries increasing emphasis has been placed on healthy lifestyles or behaviour, and some of the gains against adult mortality have been attributed to compliance with this advice. The international programmes of population surveys, the World Fertility Surveys of the 1970s and the Demographic and Health Surveys of the 1980s, had shown that child survival was associated with parental, especially maternal, education. Caldwell (1979) demonstrated that the influence of parental education was not merely a reflection of income levels but a powerful influence in its own right, and this was confirmed throughout the Third World by Hobcraft *et al.* (1984) and Cleland and van Ginnekan (1988). Mensch *et al.* (1985) calculated from a study of fifteen developing countries that the direct effect of female education was a decline of 3.4 per cent in their children's mortality for each additional year of schooling.

There was other compelling evidence of the importance of social factors in determining mortality decline. Life expectancy in Third-World countries bore little relation to per capita income levels. Sri Lanka and the Indian State, Kerala, achieved during the 1980s life expectancies of 70 years, not far behind the industrialized countries, with per capita incomes only one-fortieth of that of the rich countries and health expenditure similar to that found in other poor countries. Conversely, a range of Middle Eastern and North African countries, where women's education was low and where their autonomy was restricted, exhibited surprisingly high mortality. Caldwell (1986) attributed the successful health transitions of Sri Lanka and Kerala to a radical tradition and a high level of female autonomy in their cultures which had allowed both an early spread of female schooling and, at the individual level, a confident taking of health and treatment decisions by women with regard to their children and themselves. He pointed out that such social factors and the provision of modern health services interacted to produce low mortality, and that Sri Lanka had not achieved such success with regard to health before these services were available. The most successful health services were the most democratic ones which gave first priority to providing all sectors of the community with cheap and easy access to modern medical treatment. Mensch *et al.* (1985) showed that Third-World child survival was most strongly influenced by mother's education, father's education and ethnicity, pointing out that, in eleven plural societies investigated, there were in every case large differences in child mortality between ethnic groups even after education, income and access to medical services had been controlled. They believed their findings to 'emphasize the importance of "technique" such as childcare practices and personal hygiene relative to the importance of the sheer volume of material and monetary inputs that is reflected in such variables as income, housing facilities and residence in urban areas'. However, it might be noted that the evidence is still ambiguous as to whether the social factors involved in achieving low child mortality operate mainly through such mechanisms as care, especially in ensuring that children suffer from fewer bouts of sickness or from accidents, or whether the impact is mainly achieved through greater efficiency in interacting with the medical system once treatment is needed.

Preston and colleagues in a series of publications (e.g. Preston and Haines 1991) analysed US data at the beginning of the twentieth century and showed that the strong influence of maternal education on reducing child mortality found in the contemporary Third World was not evident in the USA of that time. Caldwell (1991) suggested that the

reason was that effective treatment requires not only modern medicine but also a belief in it and a scientific outlook that leads to unhesitating and wholehearted collaboration with health services; these attitudes were part of western society at the beginning of the twentieth century but they have largely been imported into the Third World by western education systems. Hence the effectiveness of the health system is a function of an individual's or parent's duration of education.

Efforts have been made to develop analytical methods suited to exploring the health transition (e.g. Cleland and Hill 1991). In spite of a commitment to take health or ill-health as seriously as survival or death, most health transition analyses still support their conclusions with mortality statistics. This is the case not so much because of the finality of death and because it is the ultimate proof that health interventions did not succeed, but because it can be clearly defined in contrast to measures of sickness which are often ambiguous, especially when they are the product of retrospective reports on themselves or their children by respondents in household surveys. The cultural, social and behavioural measures are even more difficult, for, while some measures of education can be agreed upon, this is far from being true with regard to female autonomy or the degree of radicalism or egalitarianism in a society.

Hegel, Georg Wilhelm F. (1770–1831)

Probably no other philosophy dominates the modern European consciousness to the same extent as Hegel's. Yet few great thinkers have been so consistently misunderstood and their teaching so distorted by friend and foe alike, even today, in spite of the work of specialist Hegel scholars, who since the 1970s have swarmed as never before. The old stereotypes still persist: the allegedly 'tender-minded' reality-behind-appearance Idealist; the arch-rationalist; the professional historian's *bête noire* with his *a priori* philosophy of history; the apologist of Prussian authoritarianism and the conservatism of the Restoration, the apostle of *Machtpolitik* and totalitarianism, if rarely in their cruder shapes yet often nowadays in more subtle and sophisticated kinds of criticism. Scholars are reluctant, even timid, to start at the other end of the spectrum: to accept Hegel without reserve as the thoroughly down-to-earth realist that he always was, interested especially in what we would call sociological phenomena (and Hegel's *Volksgeist,* for instance, is to be seen in this light and not that of Romantic nationalism); or to see him as the lifelong enthusiast for the ideals of the French Revolution, in many ways closer to Benthamite radicalism than Burkeian conservatism, who tried to use philosophy to expound the logic of the claim of modern human beings to self-realization and freedom and therefore the rationale of the modern democratic state as such, a thinker who is not outside the liberal democratic tradition, but sociologically realistic within it.

It is a strange paradox that Marx did accept much of this, precisely because in his critique of Hegel's political philosophy he was attacking the idea of the state as such, in its most plausible form, and wanted to show that it was self-contradictory, because it was an illusion of the alienated false consciousness of bourgeois society or, rather, non-society, which could not possibly become a reality in the modern world. Marx admired the detail and clarity of Hegel's account of modern society and its sociological realism only it was 'upside down', like a photographic negative. For modern Marxists it is an unshakeablc dogma that Marx demystified Hegel, removed the centre of gravity from *Geist* to humankind, and so on. In fact they have created a new myth: not the state, but what in Hegel is one of its 'moments', namely 'civil society', is all-in-all, and the state is

powerless to intervene and correct the self-destructive evils of this sphere of rampant economic liberalism that he analysed so acutely, especially the production of an alienated *'pöbel'* or proletariat. Hegel is said to be describing something on its way out. Although this sort of interpretation involves too much looking down the wrong end of the telescope, it does come closer to the real Hegel than traditional liberal distortions, for example, that Hegel equated state and society, in so far as Hegel's view of modern industrial and commercial civilization was not only profoundly critical but also closely related to a dialectic designed to develop fully the inherent self-contradictions in all partial truths, and which applies not only to thinking but also to the reality that is thought.

An interpretation which spotlights the theme of alienation generally and the need for community need not be Marxist, and in Britain and the USA especially this has been fashionable. The influence of the *Zeitgeist* seems fairly obvious in this concentration on community rather than state in Hegel, a concentration which is inclined to lean heavily on certain aspects of his immature thought, especially his enthusiasm for the 'beautiful wholeness' of the lifestyle of the ancient Greeks. The mature Hegel is then interpreted in this light.

All these interpretations suffer from failure to understand the meaning and significance of the religious dimension of Hegel's philosophy, his claim that philosophy is the fully rational truth of Christianity, and how this is reflected in the Hegelian concept or notion, the concrete universal that is the tool of Reason, as opposed to the scientific Understanding which knows its objects by separating and dividing. This means accepting the reality and necessity of continuing division and conflict for true harmony and unity in the human spirit and society, and rejecting all belief in a 'beyond' as a pathological symptom of alienation. A true unity is a unity of differences, unlike the primitive undifferentiated wholeness of the Greek *polis,* and a rational state, as understood by philosophy, will be the reverse of totalitarian: it must in fact be pluralistic, since the universal needs the particular as much as the particular needs the universal. It is the 'prodigious strength' of the modern state that it is able to contain its negation: the world of self-seeking particularity that destroyed the primitive unity of the Greek *polis.* This is the fully developed freedom (fully developed in every relevant objective sense, ethical, legal, political and social) of the modern state that makes sense of history, and whose development the philosopher can trace in history. Beyond history and the state is the timeless absolute freedom of art, religion and philosophy; the state and its freedom is not an end in itself. Hegel was in fact describing something on its way in: the *Geist* of modern humans, their claim to freedom and the institutions necessary to make that claim real. In many ways he anticipated Max Weber in his account of the modern rational state as an essentially public impersonal institution that belongs to no one but which all individuals recognize as their own in so far as it is seen to uphold their own particular interests, and which generates a perpetual tension between freedom and control, liberty and order.

In the *Grundlinien der Philosophic des Rechts* (1821) *(Philosophy of Right),* Hegel spells this out in meticulous detail far surpassing anything to be found in most philosophers who call themselves empirical, and in this he was unnecessarily and dangerously extending his lines into matters that were contingent and time-bound. But it is a superficial view that writes off this sort of thing as out-of-date: it is more rewarding

to seek the rationale that underlies such obvious anachronisms. This is in accordance with the Hegelian dialectic, which is not a strict and logically brittle deduction of 'thesis, antithesis and synthesis', but a way of thinking concretely and multidimensionally about human experience and of exhibiting such thought, which is one reason why Hegel is difficult. The only test is trueness to life. But anyone who approaches the *Philosophy of Right* in the correct spirit, a book which it should be remembered is not a 'book', but a compendium for a course of lectures, will be repeatedly struck by his soundness and common sense and be able to appreciate the force of his criticism of all abstract thinking about freedom and the state in purely legal or purely ethical or, for that matter, purely sociological modes. But a proper understanding of Hegel requires a sound knowledge of the historical background (which most critics do not have), so that one can make the necessary adjustments in order to arrive at its relevance. The beginner, however, should start with the lectures on the philosophy of history, which Hegel himself designed for beginners, though this too has its dangers. There is simply no short-cut to this philosophy, which is a circle, whose end is its beginning. Hegelian dialectic was able to bring home the bacon of sociological realism, as Marx in his own way realized, and political liberalism would have been a lot sounder and healthier if its exponents had realized it too, and not been so busy hunting ''totalitarian and 'conservative' hares, in country for which they did not possess an adequate map.

hermeneutics

Hermeneutics is a term used to describe the views of a variety of authors who have been concerned with problems of understanding and interpretation. Some of the themes of hermeneutics were introduced to English-speaking social scientists by the writings of Max Weber. As a participant in the methodological debates which occurred in Germany during the late nineteenth and early twentieth centuries, Weber was familiar with the views of philosophers and historians such as Wilhelm Dilthey, Heinrich Rickert and Wilhelm Windleband, who all argued that the study of the social and historical world requires the use of methods which are different from those employed in the investigation of natural phenomena. These arguments were reflected in Weber's own emphasis on the concept of understanding *(verstehen)*.

While Weber played an important role in introducing many social scientists to the ideas of hermeneutics, the latter tradition stretches back to a period well before Weber's

time. Hermeneutics derives from the Greek verb *hermeneuein,* which means to make something clear, to announce or to unveil a message. The discipline of hermeneutics first arose, one could say, with the interpretation of Homer and other poets during the age of the Greek Enlightenment. From then on, hermeneutics was closely linked to philology and textual criticism. It became a very important discipline during the Reformation, when Protestants challenged the right of tradition to determine the interpretation of the holy scriptures. Both classical scholars and theologians attempted to elaborate the rules and conditions which governed the valid interpretation of texts.

The scope of hermeneutics was greatly extended by Wilhelm Dilthey (in the nineteenth century). An historian as well as a philosopher, Dilthey was aware that texts were merely one form of what he called 'objectifications of life'. So the problem of interpretation had to be related to the more general question of how knowledge of the social-historical world is possible. Such knowledge is based, in Dilthey's view, on the interrelation of experience, expression and understanding. Cultural phenomena, such as texts, works of art, actions and gestures, are purposive expressions of human life. They are objectified in a sphere of conventions and values which are collectively shared, in the way that a person's attitude may be objectified in the medium of language. To understand cultural phenomena is to grasp them as objectified expressions of life; ultimately it is to re-experience the creative act, to relive the experience of another. While reorienting hermeneutics towards a reflection on the foundations of the *Geisteswissenschaften* or 'human sciences', Dilthey's writings preserved a tension between the quest for objectivity and the legacy of Romanticism.

The key figure in twentieth-century hermeneutics is Martin Heidegger. Whereas in Dilthey's work the hermeneutical problem is linked to the question of *knowledge,* in Heidegger's it is tied to the question of *being,* problems of understanding and interpretation are encountered while unfolding the fundamental features of our 'being-in-the-world'. For Heidegger, 'understanding' is first and foremost a matter of projecting what we are capable of. This anticipatory character of understanding is a reformulation, in ontological terms, of what is commonly called the 'hermeneutical circle'. Just as we understand part of a text by anticipating the structure of the whole, so too all understanding involves a 'pre-understanding' which attests to the primordial unity of subject and object. We are beings-in-the-world, familiar with and caring for what is ready-to-hand, before we are subjects claiming to have knowledge *about* objects in the world.

Heidegger's work has implications for the way that the human sciences are conceived, as Hans-Georg Gadamer has attempted to show. In *Truth and Method,* Gadamer (1975 [1960]) establishes a connection between the anticipatory character of understanding and the interrelated notions of prejudice, authority and tradition. The assumption that prejudices are necessarily negative is itself an unjustified prejudice stemming, in Gadamer's view, from the Enlightenment. It is an assumption which has prevented us from seeing that understanding always requires pre-judgement or 'prejudice', that there are 'legitimate prejudices' based on the recognition of authority, and that one form of authority which has a particular value is tradition. We are always immersed in traditions which provide us with the prejudices that make understanding possible. Hence there can be no standpoint outside of history from which the totality of historical effects could be

grasped; instead, understanding must be seen as an open and continuously renewed 'fusion' of historical 'horizons'.

Gadamer's provocative thesis was challenged in the mid-1960s by Jürgen Habermas and other representatives of 'critical theory'. While acknowledging the importance of Gadamer's hermeneutics for the philosophy of the human sciences, Habermas attacked the link between understanding and tradition. For such a link underplays the extent to which tradition may *also* be a source of power which distorts the process of communication and which calls for critical reflection. Appealing to the model of psychoanalysis, Habermas sketched the framework for a 'depth-hermeneutical' discipline which would be oriented to the idea of emancipation.

The debate between hermeneutics and critical theory has been reappraised by Paul Ricoeur (1981). As a hermeneutic philosopher concerned with critique, Ricoeur has tried to mediate between the positions of Gadamer and Habermas by re-emphasizing the concept of the text. In contrast to the experience of belonging to a tradition, the text presupposes a distance or 'distanciation' from the social, historical and psychological conditions of its production. The interpretation of a text, involving both the structural explanation of its 'sense' and the creative projection of its 'reference', thus allows for the possibility of establishing a critical relation *vis-à-vis* 'the world' as well as the self. Ricoeur shows how the model of the text and the method of text interpretation can be fruitfully extended to the study of such varied phenomena as metaphor, action and the unconscious.

As debates have indicated, the issues which for centuries have been discussed under the rubric of hermeneutics are still very much alive. The appreciation of texts and works of art, the study of action and institutions, the philosophy of science and social science: in all of these spheres, problems of understanding and interpretation are recognized as central. While few contemporary hermeneutic philosophers would wish to draw the distinction between the natural sciences and the *Geisteswissenschaften* in the way that their nineteenth-century predecessors did, many would nevertheless want to defend the peculiar character of social and historical enquiry. For the *objects* of such enquiry are the product of *subjects* capable of action and understanding, so that our knowledge of the social and historical world cannot be sharply separated from the subjects who make up that world.

hierarchy

Hierarchy is an organization in grades or orders or ranks of descending power, authority or prestige. In this general meaning, the concept has been absorbed into the social sciences and into common use. But its etymological reference is ecclesiastic. It refers to priestly government, usually to the Roman Catholic Church, but more widely to the graded organization of either angels or clergy. In classical enumeration there were nine functions or orders of the heavenly host subdivided into triads (also called hierarchies) in descending order: Seraphim, Cherubim, Thrones; Dominations, Virtues, Powers; Principalities, Archangels, Angels. The clerical hierarchy reflects the heavenly orders. Its highest triad is formed by baptism, communion and chrism (anointing). Second come the three orders of the ministry, bishops, priests and deacons. Third is the lowest triad of monks, 'initiated' and catechumens (those being prepared for baptism).

The celestial hierarchy is presumably of marginal interest to social scientists, but the earthly hierarchy is part of the complicated history of human organizations. In its modern secular usage, the word hierarchy has lost, or at least obscured, its connotation of sacredness and function as denoted in the triads described above. Yet these were essential aspects of the organization of the early Christian churches. St Paul appointed bishops at local churches with the preeminently spiritual function and spiritual authority of reproducing the Last Supper. As this duty became ritualized into the symbolic ceremony of the Eucharist the bishop was thought of as the representative of the Apostles. It may be that the original churches were collegiate, and therefore almost the opposite of the modern conception of hierarchical, in their organization, holding the authority of Christ collectively. But if so, collegial authority was soon superseded by power vested in a bishop with the presbyters as his council, and deacons appointed by him as administrative assistants. The theory thus emerged of the transmission of authority through the laying on of the bishop's hands.

Further development of the priestly hierarchy followed when Constantine made Christianity the state religion of Rome, willing that the Church be coextensive with his empire. Civil and ecclesiastical administration became standardized, the areas of civil administration being formed to coincide with the ecclesiastical diocese, larger civil regions with patriarchal regions, and the whole Church centred on the supreme patriarchate at Rome. Papal authority thus became supreme in the Church and survived the fall of the Roman Empire.

The hierarchy was challenged at various times in the Middle Ages, notably as a result of the widespread inconsistency between the personal lives of local priests and the official claims of the priesthood to authority over their parishioners. The Lutheran revolt and the ensuing Protestant Reformation challenged the evolved theory of priestly hierarchy as it had developed in imperial and medieval Rome. Luther revived the medieval concept of the secular monarch as the vicar of God on earth in opposition to papal autocracy. The monarch provided the external or secular authority of the Church; internal authority was provided by religious dedication and spiritual grace among the Church members. Calvinism, while also rejecting the Roman hierarchy, gave greater power to its ministers and did not accord supremacy to the state. Calvin's ministers were held to be recipients of divine authority, but it was a collegiate authority vested not in Pope or bishop, but in the representatives chosen from a single united order. In the Church of England the reformed hierarchy is best described as the continuation of Catholicism without the Pope.

Thus the forms of authority and the division of powers and functions between state and church, ministry and laity, vary considerbly within Christendom. But all remain hierarchical in the original sense of organizing a divine spiritual authority.

The use of the term hierarchy in modern social science typically lacks this religious reference. Dumont (1970) defines it as 'a ladder of command in which the lower rungs are encompassed in the higher ones in regular succession'. He has in mind here a version of the *Shorter Oxford Dictionary* definition—'a body of persons or things ranked in grades, orders or classes one above another'. He refers to Talcott Parsons's (1954) conception of social stratification as a system of ranking based on *evaluation,* which fundamental process of human interaction tends to differentiate individuals and groups into a rank order. From this starting-point Dumont develops a comprehensive analysis of the caste system as a hierarchical order.

Caste systems, viewed as a special case of status systems, are essentially hierarchical in the Parsonian sense. Hierarchy can be detached from its religious context and used to describe systems of rank where the elements or strata are judged in relation to the whole. Hierarchy then takes its place as a special form of what is treated in modern sociology and anthropology under the heading of social stratification.

historical demography

The relative growth and decline of populations has been a fundamental concern of modern political and economic theorists since Machiavelli and Boisguilbert, and a sophisticated algebra of human numbers began as early as the seventeenth century. Malthus (1986) and his nineteenth-century contemporaries observed that human numbers are checked not only by mortality but also by institutions and customs which keep fertility well below biological maximum for the species, like delayed marriage. The development of a general method of analysing how these and other factors structured populations in the past, however, dates only to the 1950s, when a new approach was initiated by the French demographer, Louis Henry. He formulated rules which showed how to codify the mass of baptisms, burials and marriages recorded in parish records before 1800, defining each individual as a member of a reconstituted family over a specific duration (Fleury and Henry 1965). While Henry's method created new opportunities for technical demographic innovation, its main impact as the field has developed has been to show how the demographic constitution of a society can act as a primary factor shaping social and economic change. Historical demography has in consequence come to play an important interdisciplinary role, entering into concepts and methods employed by anthropologists, geographers and sociologists, as well as social and economic historians.

This breadth of interest reflects the shift in historical focus implied in Henry's approach. Detailed family histories had hitherto been available for some elite populations, but, following Henry, it became possible to trace, individual and family life courses for a substantial sample of an entire community. At base, the method entails systematic tracing of individual and family names in parish records ('nominal linkage'). The changing family structures to which this process gives rise then serve as a framework for integrating information on the same names or lives as they appear in a wider body of sources: civil, ecclesiastical and manorial court records; wills and inventories; census lists; Poor Law records; diaries and memoirs; and so forth. Once articulated in this way, many features of local society may be examined, notably the operation of social control, social and geographical mobility, interrelations between economic and health conditions, and the operation of land tenure and inheritance systems. Although developed initially with reference to European populations, this methodology has proven applicable to sources elsewhere, notably in China, Japan and the Americas.

One of the most fruitful lines of enquiry has addressed what Henry called 'natural fertility', that is, analysis of the set of factors (nuptiality, breastfeeding, foetal mortality, coital frequency, etc.) which regulate reproduction in the absence of modern contraceptive methods and strategies of fertility control. Reconstitution studies have

established that a tremendous diversity characterized pre-industrial demographic systems. Very few groups practised birth control, yet completed family sizes have been found to vary from 2.9 to 11.4 births per woman. At the same time, infant mortality rates ranged from 140 to 280 per 1,000, rising in unfavourable circumstances to more than 400 per 1,000. These results overturn generally accepted notions that large families were everywhere the norm in past times, and that traditional rural societies were locked in a race that pitted high fertility against high mortality in an inexorable struggle to ensure social survival.

Debunking common myths about our demographic pasts has, in turn, encouraged rethinking the conventional view of population as a dependent variable in socioeconomic theory. Hajnal (1965), for instance, has identified a characteristic European marriage pattern, extant as early as the sixteenth century, in which women did not marry on average until age 23, and up to 15–20 per cent remained unmarried. In places like England, relatively small family sizes consequent on this pattern preceded rather than followed modern economic development. Viewed in aggregate terms, this marriage pattern carried important economic advantages: delayed marriage and correspondingly lower fertility were mechanisms which helped families to cope when times were hard and new economic opportunities scarce; conversely, the 'nuptiality valve' was flexible, opening up as circumstances improved to allow earlier marriage and renewed population growth, with their implications for expanding labour resources and markets. However, viewed at the local level, with the assistance of record linkage, it becomes clear that the timing of marriage carried strategic advantages with regard to much more than aggregate economic conditions. Even within the same community, different occupational, class, ethnic and religious groups could have different reproductive patterns and family compositions, reflecting the interplay of natural fertility and mortality with local institutions and values. These findings are echoed in research on a more recent phase in population history, known as the demographic transition. Coale and Watkins (1986), in reanalysing European census data on a province-by-province basis, have shown that declining family size in the late nineteenth and twentieth centuries cannot be accounted for adequately in terms of macro-level socioeconomic correlations. Attention has turned instead to examining how aggregate shifts in marriage and reproduction were expressions of a welter of institutional and cultural arrangements operating at several subnational levels.

Opening up new perspectives and extensive bodies of data has inevitably posed technical problems for historical demography. Perhaps the greatest difficulties arise in the attempt to move from local to aggregative levels of analysis. The calculation of conventional demographic measures requires record both of the incidence of births, deaths and marriages, and of the total populations at risk of experiencing these events. Family reconstitution, in supplying the former, provides many checks on the internal consistency of data. But it generally cannot supply the latter owing to well-known limitations of parish registers in most countries. These sources tend to give a very partial picture of migrants. They exclude members of important religious and ethnic groups. In many places records have been lost or were badly kept, especially for crucial urban populations. The distribution of reliable records, therefore, when viewed from a regional or national perspective, is far from uniform, and requires careful selection and

adjustment. Pioneering work on these problems by Wrigley and Schofield (1981) has shown how representative samples may be established, and also how conventional demographic techniques used to forecast future population structures can be modified to generate population sizes and structures at successively earlier historical periods. The limitations and possible generalizability of their approach are currently the focus of much discussion.

historical geography

Historical geography has had a variety of meanings. Once used as a synonym for the history of geographical thought, it has long since ceased to be so employed. In the nineteenth and early-twentieth centuries it was commonly used to embrace the history of exploration and discovery, of mapping the earth, and of changes in political and administrative boundaries. But the birth and infancy of modern historical geography as the geographical study of the past can be traced to the 1920s and 1930s; by the mid-1960s it had matured into a distinctive discipline concerned not only with reconstructing past geographies but also with studying geographical changes.

A significant definition of the discipline was provided by H.C.Darby (1962) in a major statement which integrated old and new views by identifying four main approaches to historical geography: first, geographies of the past—'horizontal' cross-sections of the geography of an area at some past time; second, changing landscapes—'vertical' themes

of landscape transformation, such as the clearing of woodlands and the draining of marshes; third, the past in the present—historical explanations of the present-day geography of a place; fourth, geographical history—investigation of the influence of geographical conditions (environmental and locational) upon the course of history. Historical geography within this mould came to be characterized as an approach in which the data were historical but in which the problems and methods were geographical: it emphasized mapping historical sources in order to demonstrate regional differences in past times and changing landscapes during past periods. The method was demonstrated *par excellence* in Darby's work on the Domesday geographies and on the draining of the Fens (Darby 1940; 1952–77).

From the early 1970s the Darbian tradition of an historical geography grounded in source-based empiricism and methodological pragmatism came increasingly and importantly to be interrogated in the light of developments in contemporary human geography and in the social sciences in general. An initial willingness by some historical geographers to participate in attempts to 'explain' the world though general theories of spatial organization was soon replaced by a wider rejection, or at best limited acceptance, of positivist spatial science when applied to historical studies, and then by a deliberate endeavour to explore other approaches to historico-geographical enquiry, involving encounters with historical materialism and humanistic idealism. Significantly, historical geographers have been in the forefront of the attack on positivist spatial science while at the same time deploying social theory in geography and arguing the case for the geographical imagination in social science. With a renewed recognition both of the need for an historical perspective within contemporary human geography and for a geographical perspective within history (and the social sciences), historical geography is making a vital contribution both to its parent and to cognate disciplines.

Historical geography as the study of past (largely human) geographies reflects the diversity of geography itself. It embraces not only geography's traditional, central concerns with regions, places and areas but also the modern, peripheral concerns of the ecological, locational and landscape schools of geography.

First, some notable books and atlases have been published treating the historical geographies of particular countries, areas and continents. Second, other studies focus upon the changing relationships of people with their physical environments, with the impact of cultures upon natural ecologies. Such studies themselves take a variety of forms: some are concerned with tracing historically the interactions between peoples and their physical environments which provide the material resources for sustaining both life and distinctive lifestyles in particular places; others are concerned with reconstructing historical geosophies, with questions about people's perceptions (and misperceptions) of their physical environments; while other studies monitor the impact of peoples upon their physical environments, engaging with questions about environmental management (and mismanagement) in the past.

Third, within historical geography there is a long-established school of location and diffusion studies, concerned with the spread of phenomena over space and through time. For long associated with the work of Carl Sauer and the Berkeley school of cultural geography in North America, diffusion studies have themselves changed under the impact of Torsten Hägerstrand, a Swedish geographer, so that they now range from

informal, qualitative studies of the spread of the domestication of plants and animals to formal, quantitative studies of the spread of agricultural innovations and of diseases.

Finally, the landscape school within historical geography is similarly represented by contrasting approaches: some studies remain focused upon reconstructing the transformation of landscapes by human (principally economic) activity, while others explore the symbolic design and representation of landscapes, and the decoding of their meanings and iconographies.

historical linguistics

Historical linguistics, as opposed to the history of linguistics, is the study, reconstruction, theoretical explication and modelling of language change over time. It is the linguistic counterpart of (diachronic) cultural anthropology, cultural or social history, or evolutionary biology.

In the nineteenth century, linguistics *was* predominantly historical: it was the study of evolution and change, not of structure. Following Saussure's (1916) radical dichotomy of linguistics into synchronic and diachronic studies as mutually exclusive pursuits, there was a reversal of interest, a period lasting well into the 1960s, when (in the English-speaking world at least) 'prestige' linguistics was synchronic ('structural'), and historical linguistics was either a minority pursuit of general linguists, or, from the linguist's point of view, an autonomous backwater institutionalized in the universities and journals as comparative philology, or history of English/German, and so on. (There are notable European exceptions, for example the work of the Prague School, and American exceptions in the work of Sapir, Bloomfield, Hockett, and others—but the generalization holds overall.)

As interest shifted from primary concern with data-processing to deeper theoretical concerns, often with explanatory pretensions (Lass 1980), historical linguistics gradually became integrated as a subfield of general linguistics. Each succeeding or competing school (paradigm) developed a synthesis, in which techniques of synchronic description and analysis and explanatory claims were applied to historical data, and often (partly at least) validated by their diachronic success. (This assumed, perhaps reasonably, that theories of what something *is* ought to bear on theories of its mutations over time: this could be compared to the largely successful wedding of synchronic genetics and evolutionary theory in biology.)

Historical linguistics follows four main lines of enquiry.

'Factual'/'Reconstructive'

This area covers three traditional activities: first, reconstructing unattested *états de langue* on the basis of comparison of descendant forms in different languages (for example, Proto-Indo-European **yúg-o-m* 'yoke' on the basis of Latin *jug-u-m,* Greek *zúg-o-n,* Sanskrit *yúg-a-m,* and so on; second, construction of chronicle histories of languages or language families (including reworkings of older histories on the basis of new evidence

or interpretation); third, etymology or constructing phonological and semantic histories of particular words or groups, often showing up relations among forms that seem at first unrelated (such as the connection between *feather,* Greek *pétros* 'rock', and Latin *petere* 'strive' established by Maher 1973). These activities were the foundation of the discipline and are still practised, applied in some cases to unwritten or exotic language families (see Dixon 1980 on Australian) or to microhistories of unexplored aspects of familiar languages (see Lass 1976 on neglected pieces of the history of English).

Theoretical Interpretative

The reinterpretation of known histories of languages in terms of current (often competing) research paradigms, and the use of historical data to make general theoretical points or validate particular models. Examples are the structuralist synthesis in Hoenigswald (1960) and the generativist synthesis in King (1969). Lightfoot (1979) attempted to reinterpret aspects of the history of English syntax in the light of a 'restrictive' transformational theory. Harris (1979) produced a history of French syntax drawing on work in word-order typology and theories of syntactic universals.

Sociolinguistic

Contemporary quantitative methods of studying linguistic variation in speech communities, especially the covariation of linguistic and social variables, have led to apparent observations of change in progress (something formerly thought impossible). These studies (e.g. Labov *et al.* 1972; Trudgill 1974), while not strictly historical, have none the less had a profound impact on historians, as they have for the first time made clear the primary mechanism of historical change—variation, cumulatively weighted in particular directions.

Sociohistorical linguistics

Sociolinguistic theory has been projected into history to form a new subdiscipline, sociohistorical linguistics, which is a major synthesis of these two directions, and is perhaps the most important contemporary development in the field (Romaine 1980).

history

History has some claim to be considered one of the world's oldest professions, and the subject was taught in some European universities, from Oxford to Göttingen, in the seventeenth and eighteenth centuries (Gilbert 1977). However, the rise of history as an academic discipline in the west coincided with the rise of the social sciences in the nineteenth century. The relation of historians to these subjects was often one of rivalry and conflict. Inspired by the work of Leopold von Ranke (1795–1886), historians were moving away from the history of society which some of them had practised in the eighteenth century and concentrating their attention on the production of narratives of political events firmly based on official documents. They tended to define their discipline by contrast to the social sciences, especially to sociology, although they were often interested in geography as a handmaid to their subject, while a handful of economic historians, such as Gustav Schmoller (1838–1917) had an interest in economic theory. Karl Lamprecht (1856–1915) in Germany and James Harvey Robinson (1863–1936) and others in the USA advocated a new kind of history which would pay considerable attention to culture and society and also draw on the concepts and theories of social scientists, but these historians were isolated among their professional colleagues. At the end of the nineteenth century, the conventional wisdom of the historian's craft, expressed in philosophical form by Wilhelm Dilthey (1833–1911), Wilhelm Windelband (1848–1915), Heinrich Rickert (1863–1936) and Benedetto Croce (1866–1952), was that history was concerned with unique events (leaving the establishment of general laws to the social

sciences), and that historians tried to understand the past from within (while social scientists attempted to explain it from outside). For their part, sociologists such as Auguste Comte (1798–1857) and Herbert Spencer (1820–1903) regarded historians as at best collectors of raw material for theorists to utilize.

This intellectual landscape had not changed very much by the middle of the twentieth century. In Britain, for example, the views associated with Dilthey and Croce were reiterated with force by R.G.Collingwood (1888–1943), the one philosopher of history to be taken seriously in the English-speaking world (perhaps because he doubled as a historian of Roman Britain). There had been a few rebellions against the hegemony of political narrative, but in 1950 they could not yet be described as successful. Marxist historians had not yet produced many important works—the exceptions include Jan Romein's *The Lowlands by the Sea* (1934) and Emilio Sereni's *Capitalism in the Countryside* (1947). Only in two areas was change truly visible. Economic historians had become a significant group within the profession, with their own journals, such as the *Economic History Review,* their own heroes, such as the Belgian Henri Pirenne (1862–1935) and the Swede Eli Heckscher (1879 1952), and their own debates, which often had more in common with debates among economists than with those of their fellow-historians. In France, a broader approach to history, inspired by Lucien Febvre (1878–1956) and Marc Bloch (1886–1944) and associated with the journal *Annales,* had begun to attract attention, and a remarkable work on the Mediterranean world in the age of Philip II was published in 1949 by Fernand Braudel (1902–85), particularly original in its exploration of what the author called 'geohistory', a historical geography influenced by the work of Vidal de la Blache but rather more deterministic.

Retrospectively, the 1950s now appear to be something of a historiographical turning-point. Serious Marxist history finally came on stream, generally produced outside the communist bloc (by Eric Hobsbawm and Edward Thompson in Britain, Pierre Vilar in France, etc.), but occasionally within it—an outstanding example being the work of the Polish economic historian Witold Kula (1916–88). In France, the *Annales* group, under Braudel's leadership, came to dominate the profession, both intellectually and institutionally. In the USA, France, and elsewhere, the 'new economic history', like economics, became increasingly ambitious in its aims, and quantitative in its methods. It was sometimes taken as a model for other kinds of history. Historical demography, for instance, which emerged as a sub-discipline in the 1950s (inspired by increasing concern with contemporary population growth), is a form of quantitative social history (Wrigley 1969). Other social historians and historical sociologists also took a quantitative turn at this time, though some resisted; E.P. Thompson's classic study *The Making of the English Working Class* (1963) contains a characteristically savage critique of what the author called sociology, more exactly the quantitative historical sociology of Talcott Parsons's follower Neil Smelser, who had recently written about the Industrial Revolution. Quantification also played an important role in the 'new political history', practised in the USA in particular, whether the emphasis fell on election results, voting patterns in Congress, or attempts to count strikes and other forms of protest (Bogue 1983). Similar methods were applied to religious history, particularly in France, with statistics for annual confession and communion taking the place of voting figures. For example, in his original and controversial book on 'baroque piety and dechristianisation',

Michel Vovelle (1973) studied some 30,000 wills from eighteenth-century Provence, using them as indexes of views of death and of changes in religious attitudes. His work offered a possible link between cliometrics and another concern of the 1950s, 'psychohistory'. In France, following the tradition of Durkheim and Lucien Levy-Bruhl (1857–1939), interest in historical psychology focused not on individuals but on collective mentalities, as in a series of studies by Philippe Ariès (1914–84) on changing attitudes to childhood and to death over the centuries. A few bold spirits, among them the French medievalist Jacques Le Goff, attempted to study mentalities in the manner of Claude Lévi-Strauss, emphasizing binary oppositions in general and the opposition between nature and culture in particular. In the USA, where the ideas of Sigmund Freud were more deeply embedded in the culture than elsewhere, some historians and psychoanalysts attempted to study the motives and drives of religious and political leaders such as Martin Luther, Woodrow Wilson, Lenin and Gandhi, while a president of the American Historical Association invited his colleagues to consider psychohistory as their 'next assignment' (Langer 1958).

With few exceptions, historians failed to respond to Langer's invitation. What some of them did do in the 1970s, like their colleagues in related disciplines, to some extent as a reaction to the events of 1968, was to reject determinism (economic or geographical), as they rejected quantitative methods and the claim of the social sciences to be scientific. In the case of history, this rejection of the work of the previous generation was accompanied by new approaches to the past, four in particular, which can be summed up by four slogans in four languages: 'history from below', *microstoria, Alltagsgeschichte,* and *histoire de l'imaginaire.*

First, 'history from below', is an ambiguous term, and both meanings are important: not only the history of ordinary people in the past but also history written from the point of view of ordinary people. It is perhaps the most important change in the discipline in the twentieth century, a true Copernican Revolution in historical writing which compensates for the inadequacies of a tradition of elitist historiography that ignored the experiences, the culture and the aspirations of dominated groups (Guha 1982). This shift has encouraged and has in turn been encouraged by the rise of oral history, giving ordinary people an opportunity to describe their experience of the historical process in their own words. However, the practice of history from below has turned out to be much less simple than was originally thought, largely because of differences between different kinds of dominated groups—the working class, the peasantry, the colonized, and of course women. It was around the 1970s that the movement for women's history became generally visible, thanks to the rise of women's studies and feminism, and the result was to undermine any assumption of the unity of the 'subordinate classes'. In the second place, the study of the working class, or of women, or of popular culture, in isolation from the study of the middle class, or men, or elite culture, is now generally considered to be misleading, and attention is turning to the relations between these different groups.

Second, *microstoria* or microhistory may be defined as a concern with the past at the level of a small community, whether village, street, family or even individual, an examination of 'faces in the crowd' which allows concrete experience to re-enter social history. This approach was put on the historical map by Carlo Ginzburg's *Cheese and Worms* (1976), a study of the cosmos of a sixteenth-century Italian miller, as revealed in

his replies to interrogations by the Inquisition, and by Emmanuel le Roy Ladurie's *Montaillou* (1975), which was also based on inquisitorial records and used them to produce a portrait of a fourteenth-century village which the author himself compared to community studies such as Ronald Blythe's *Akenfield*. These two books were not only bestsellers but also exemplary in the sense of inspiring a school or at least a trend. Condemned by more traditional historians as a kind of antiquarianism and as a dereliction of the historian's duty to explain how the modern world emerged, microhistory has been defended by one of its leading practitioners, Giovanni Lévi (1991), on the grounds that the reduction of scale reveals how political and social rules often do not work in practice and how individuals can make spaces for themselves in the interstices between institutions.

Third, *Alltagsgeschichte* or 'the history of the everyday' is an approach which developed, or was at least defined in Germany, drawing on a philosophical and sociological tradition which includes Alfred Schutz (1899–1959) and Erving Goffman (1922–82), Henri Lefebvre-and Michel de Certeau (1925–86). Like microhistory, with which it overlaps, the history of the everyday has been important as a way of reinserting human experience into social history, which was perceived by some of its practitioners as becoming increasingly abstract and faceless. The approach has been criticized for its concern with what the critics call trivialities, as well as for ignoring politics, but it has been defended, in much the same way that microhistory has been defended, on the grounds that it shows how trifles may be clues to important, subterranean changes (Lüdtke 1982).

Fourth, *histoire de l'imaginaire* or the history of mentalities might be defined as the everyday version of intellectual history or the history of ideas, in other words the history of habits of thought or unspoken assumptions rather than of ideas which have been consciously formulated by philosophers and other theorists. This approach, which originated in France in the 1920s and 1930s, has gone through something of a revival. As not infrequently happens in these cases, however, what is revived is not quite the same as what had existed earlier. Historians working in this area show an increasing concern with 'representations' (literary, visual or mental), and also with what French historians, following Jacques Lacan and Michel Foucault, call the *imaginaire* (perhaps best translated as the 'imagined' rather than the 'imaginary'). With this shift has come what is often called a new emphasis on the construction, constitution or 'social production' not only of different forms of culture—the 'invention of traditions', for example—but also of states and societies, which are now often viewed not as hard or objective structures, but rather as 'imagined communities' (Anderson 1991; Hobsbawm and Ranger 1983). In other words, historians like their colleagues in other disciplines are experiencing the effects of the 'linguistic turn'.

It is worth noting that all four of the approaches described are linked in some way to social anthropology, since anthropologists are concerned with 'the native's point of view' and work in small communities, observing everyday life and studying modes of thought or belief systems. Indeed, a number of historians practising these approaches would describe themselves as historical anthropologists, and introduce their work with references to E.E.Evans-Pritchard, to Victor Turner or, most often, to Clifford Geertz (Walters 1980).

Despite the importance of these four linked trends, they are not sufficient to describe recent changes in historical writing (let alone to characterize the work of more traditional historians). As was only to be expected, there are movements in different and even in opposite directions. While some scholars try to observe social change through the microscope, others, in the spirit of the 'total history' preached and practised by Fernand Braudel, try to look at the world as a whole. The best-known representative of this approach, apart from Braudel himself, is Immanuel Wallerstein, a sociologist of Africa turned historian of capitalism, in a series of volumes on 'the modern world-system'. Marxist in inspiration, these influential volumes draw on the economics of development and world systems theory in order to show connections between the rise of Venice and Amsterdam and the underdevelopment of eastern Europe and South America (Wallerstein 1974–). As might have been predicted, other attempts to see the history of planet earth as a whole have adopted an ecological viewpoint, examining, for instance, the consequences of the encounter between Europe and America as a 'Columbian exchange' of plants, animals, and, not least, diseases, and so 'placing Nature in History' (Crosby 1972). Braudel's geo-history has come to look rather static in the light of current concerns with the interaction between the landscape and its human and animal populations (Cronon 1990; Worst 1988).

At the same time as these new developments, and in reaction to some of them, readers of history have witnessed two revivals, the revival of politics and the revival of narrative. There have been many pleas by historians to put politics back into history, if not to restore its former dominance. In some respects the climate of the 1980s and 1990s has been favourable to a revival of politics, since the general rejection of determinism has made room for discussions of strategy and tactics which we may call political. However, under the influence of the trends discussed above, political history has been reconstructed to include what Michel Foucault described as micropolitics—in other words, strategies and tactics at the level of the village or the family as well as that of the state. Even diplomatic history, necessarily focused on states, has widened its concerns to include an interest in mentalities and in rituals.

More frequently discussed and more controversial is the trend towards the revival of narrative and of the history of events once so forcefully dismissed by the leaders of the *Annales* School (Stone 1979). As in the case of politics, the term revival is somewhat misleading. The history of events used to be written as if the past included nothing else, whereas historians, like some sociologists and anthropologists, are now explicitly concerned with the relation between events and structures (whether these structures are social or cultural, if that distinction still makes sense). As for narrative, it has returned in a new form, or more exactly a variety of new forms, since at least a few historians—like their sociological and anthropological colleagues are conscious of their use of rhetoric, interested in literary experiment, and even (like some contemporary novelists) in transgressing the traditional boundaries between fact and fiction (White 1978). One of these new forms is the narrative of small-scale events, a technique commonly deployed by microhistorians, and a considerable contrast to the traditional Grand Narrative which emphasized key events and dates such as 1066, 1492, 1789, 1914, and so on. Another is the story told from more than one viewpoint, in order to accommodate differences in the perception of events from above and from below, by opposite sides in a civil war, and so

on. Given current interest in encounters between cultures, it is likely that this dialogic form of narrative will be practised more and more frequently in the future. As this entry takes the form of a monologue, this is perhaps the moment to draw attention to the fact that it has itself been written from a particular point of view, that of a middle-class Englishman, and that—like most articles in this volume—it is especially though not exclusively concerned with developments in the west.

history of medicine

Doctors have long been conscious of traditions of the past. One of the Hippocratic treatises (third century BC) was entitled *Ancient Medicine,* and the veneration long accorded to the Hippocratics, Galen and other ancient medical writers guaranteed a steady stream of editions of classical authors well into the seventeenth century. From the eighteenth century, historical surveys of medicine began to be produced by doctors such as John Freind, Daniel Leclerc and Kurt Sprengel. Physicians seeking membership in the Royal College of Physicians of London were still expected to be literate in the literature of antiquity until the mid-nineteenth century, but the growth of science within medicine, the development of national traditions within Europe and places where European influences dominated, and the increased use of the vernacular in teaching and writing gradually raised awareness of the present at the expense of the past, rendering the ancients genuinely *historical* figures.

In late nineteenth-century Germany, the history of medicine was energetically pursued by a number of doctors and philologists, and Institutes for the History of Medicine were established in several universities, most importantly in Leipzig, where Karl Sudhoff held the chair from 1905 to 1925. Henry Sigerist, Owsei Temkin and Erwin Ackerknecht all worked in Leipzig before emigrating to the USA, from the late 1920s. Whereas the history of medicine had previously been viewed as part of cultural or intellectual history, Sigerist brought to his scholarship a vision of the wider social forces which have always shaped notions of health and disease, and the doctor-patient encounter. As director of the Institute of the History of Medicine at Johns Hopkins University from 1932, Sigerist helped create a small professional discipline in his adopted country, and encouraged doctors to take seriously the study of their profession's past.

By the 1950s, medical history was being taught within a few medical schools in the USA, Germany, Spain and several other countries, and most professional medical historians came to the subject from a medical background. At the same time, parallel developments in the history of science helped foster a wider scholarly community. Most historians were comfortable operating within the ordinary conventions of 'Whiggism' (Herbert Butterfield's phrase), in which the study of medical history revealed the gradual triumph of truth over error, and science over superstition.

Since the 1960s, the practice of medical history has changed. From being a subject pursued largely by doctors for doctors, it has become the concern of scholars from many disciplines, including *(inter alia)* economic and social history, historical demography, sociology and anthropology. This has meant that the centre of gravity of academic history of medicine has shifted from the medical schools to social sciences departments.

Allied to this has been the greater range of sources brought to the discipline. Traditionally, medical historians concentrated on the great names and famous achievements of the past. Medical historians are now as likely to be interested in health as in the history of disease and discovery, to be concerned with the ordinary and mundane as

with the elite, to write about the patient as the doctor. To this end, new kinds of printed and manuscript sources as well as artefacts have been put to the service of medical history. These include such materials as self-help manuals and advice books, diaries and personal papers of ordinary doctors as well as sufferers, the administrative and financial records of medical institutions, case books and iconographical material, legal records and theological tracts. Once health is included in the discipline's brief, the terrain becomes very wide.

The medical history being written today is more probing than of old. It has challenged comfortable notions of inevitable progress and disinterested professional behaviour. Several topics have been actively pursued. Following Michel Foucault's pioneering work in the 1960s, the history of psychiatry has attracted much attention. Historians have argued that definitions of mental disorder are historically contingent and psychiatry itself has been an agent of social control. Fringe and alternative practitioners have been rescued from historical oblivion. Tropical medicine has been revealed to be a tool of empire. Women, both as healers and as sufferers, have been minutely scrutinized. The politics of health and welfare have been analysed.

To accommodate these kinds of enquiries, a number of new journals and societies have been established. These have supplemented rather than replaced more traditional outlets and associations, and tensions between doctors and historians occasionally surface. The social history of medicine has been accused of having left the medicine out. Nevertheless, the subject has expanded and become more confident, even in an era of widespread academic retrenchment.

Hobbes, Thomas (1588–1679)

Thomas Hobbes is one of the most important figures in the development of modern science and modern politics. As a contemporary of Bacon, Galileo and Descartes, he

contributed to the radical critique of medieval Scholasticism and classical philosophy that marked the beginning of the modern age. But he alone sought to develop a comprehensive philosophy—one that treated natural science, political science and theory of scientific method in a unified system. He published this system in three volumes, under the titles *Body* (1655), *Man* (1657) and *Citizen* (1642). In the course of his long career, Hobbes also published treatises on mathematics, on free will and determinism, on the English common law system, and on the English Civil War. Although his work covered the whole of philosophy, Hobbes made his greatest contribution to modern thought in the field of political philosophy. On three separate occasions, he presented his theory of humankind and the state; the most famous of his political treatises, the *Leviathan* (1651), is generally recognized as the greatest work of political philosophy in the English language.

In all branches of knowledge, Hobbes's thought is characterized by a pervasive sense that the ancient and medieval philosophers had failed to discover true knowledge, and that a new alternative was urgently needed. It is this sense that defines Hobbes as a modern thinker and gives his work its originality, verve and self-conscious radicalism. In natural science (metaphysics and physics), he rejected the Scholastic and Aristotelian ideas of abstract essences and immaterial causes as nothing more than vain and empty speech. The nature of reality is matter in motion, which implied that all phenomena of nature and human nature could be explained in terms of mechanical causation. In the theory of science, Hobbes dismissed the disputative method of Scholasticism and classical dialectics as forms of rhetoric that merely appealed to the authority of common opinion and produced endless verbal controversies. The correct method of reasoning combined the resolutive-compositive method of Galileo and the deductive method of Euclidean geometry. By combining these, Hobbes believed that every branch of knowledge, including the study of politics, could be turned into an exact deductive science.

In political science proper, Hobbes was no less radical in his rejection of the tradition. He opposed the republicanism of classical antiquity, the ecclesiastical politics of medieval Europe, and the doctrine of mixed-monarchy prevalent in seventeenth-century England. All these doctrines, Hobbes claimed, were seditious in intent or effect, because they were derived from 'higher' laws that allowed people to appeal to a standard above the will of the sovereign. Hobbes blamed such appeals, exploited by ambitious priests and political demagogues, for the political instability of his times, culminating in the English Civil War. The solution he proposed was political absolutism—the unification of sovereignty in an all-powerful state that derived its authority not from higher laws but from *de facto* power and the consent of the people.

With these three teachings—mechanistic materialism, exact deductive science, and political absolutism—Hobbes sought to establish science and politics on a new foundation that would produce certain knowledge and lasting civil peace.

From the first, Hobbes's philosophical system generated controversy. In the seventeenth century, Hobbes was treated as a dangerous subversive by all who believed in, or had an interest in, the traditional order. Christian clergymen condemned his materialist view of the world as atheistic and his mechanistic view of humankind as soulless; legal scholars attacked his doctrine of absolutism for placing the sovereign

above the civil laws; even kings, whose power Hobbes sought to augment, were wary of accepting the teaching that political authority rested on force and consent rather than on divine right (Mintz 1962). In the eighteenth and nineteenth centuries his defence of absolute and arbitrary power ran counter to the general demand for constitutional government. Hobbes has been treated more favourably in the twentieth century then ever before. Although some scholars have seen certain parallels between Hobbes's Leviathan state and twentieth-century tyrannies (Collingwood 1942), most clearly recognize that Hobbes's enlightened despot, whose primary goal is to secure civil peace, is vastly different from the brutal and fanatical heads of totalitarian states (Strauss 1959).

Such studies can be divided into four groups, each reflecting the perspective of a contemporary school of philosophy as it probes the origins of modernity. First, guided by the concerns of contemporary analytical philosophy, one group argues for the primacy of method and formal logic in Hobbes's system and views his politics as a set of formal rules which serve as utilitarian guidelines for the state (McNeilly 1968; Watkins 1965). A second group has examined Hobbes's theory of political obligation from a Kantian point of view. According to this interpretation, Hobbes's argument for obedience goes beyond calculations of utility by appealing to a sense of moral duty in keeping the social contract, and by requiring citizens to have just intentions (Taylor 1938; Warrender 1957). Developed by Marxist scholars, a third interpretation uses Hobbes to understand the ideological origins of bourgeois society and to provide a critical perspective on bourgeois liberalism by exposing its Hobbesian roots (Coleman 1977; Macpherson 1962). The fourth interpretation reflects the concerns of the natural law school. According to the foremost scholar of this school, Hobbes is the decisive figure in transforming the natural law tradition from classical natural right to modern natural 'rights'; Hobbes accomplished this revolution by asserting that the right of self-preservation, grounded in the fear of violent death, is the only justifiable moral claim (Strauss 1936).

homosexualities

Homosexuality is a category invented as an object of scientific investigation by a Hungarian doctor, Benkert, in 1869, amidst a flurry of attempts to classify sexuality (Foucault 1979). It is hence a distinctively modern term. By contrast, same-sex erotic experiences have existed across time and space with varying degrees of visibility, frequency and social organization. In different parts of the world, homosexualities assume widely divergent forms from male cult prostitution to female romantic friendships; they may be patterned by age as in ancient Greece or some societies like the Sambia; by gender as in the North American Berdache; or by class, as in master-slave relations in antiquity (Faderman 1981; Greenberg 1988). There is no unitary experience.

It is not quite clear when the distinctive modern or western form emerged. Some connect it to the rise of capitalism, others to the emergence of a modern medicine, still others to the emergence of major urban centres. However it emerged, throughout the past two centuries, homosexuality has been seen negatively—as sin, sickness or crime. Until the 1970s, the dominant mode of thinking about homosexuality in the west was clinical: caused by degeneracy, biological anomaly or family pathology, and treatments ranging from castration to psychoanalysis were advocated. While such approaches do still continue, since 1973 the American Psychiatric Association has officially removed homosexuality from its nomenclature. Homosexuality is no longer a sickness (Lewes 1988). Male homosexuality has also been illegal in most European countries and US states; not until the 1960s—a decade after the decriminalizing proposals of the British Wolfenden Report and the American model penal code of 1955 proposed by the American Law Institute did the legal situation significantly change.

Throughout this time of hostility, there were always challenges. Magnus Hirschfield established the Institute for Sexual Science in Berlin in 1897 and campaigned for acceptance of homosexuality till the 1930s when the Nazis started their policy of extermination (Plant 1986). Others—Carpenter and Wilde in England, Gide and Genet in France—were pursuing literary defences (Dollimore 1991). It was not until the period after the Second World War that a substantial body of published research suggested the ubiquity and normality of homosexual experience. The Kinsey Reports in 1948 and 1953 suggested that 37 per cent of men had some post-adolescent homosexual orgasm and 4 per cent had a preponderance of such experience (13 per cent and 3 per cent, respectively, for women). Kinsey also suggested there was a continuum of homosexual-heterosexual attraction (on a scale of 1 to 6) and that homosexuality was to be found in all walks of life.

There was a progressive build-up of homophile organizations through the twentieth century, but it is the New York Stonewall Riots of 27–8 June 1969 that is generally considered to symbolize the birth of the modern international Gay and Lesbian

Movement (Adam 1987). The scientifically imposed term 'homosexual' was shifted to the self-created ones of 'lesbian' and 'gay'; pathological medical rhetoric was converted to the political language of 'gay is good'; a wide array of organizations for gays and lesbians became widespread in most large cities; and millions of gay men and women started to 'come out' and identify positively with the category 'gay'. Over the next twenty-five years, the gay and lesbian community was to become a visible and powerful social community, political lobby and 'pink economy' on a global scale.

A striking, and unexpected, development was the arrival of AIDS and HIV infection around 1981. Although AIDS concerns many people, in the western world it has had a disproportionate impact upon gay men both as sickness and as symbol. As sickness, many gay men in major cities (like San Francisco) have found their lives disrupted by a life-threatening disease, and have developed self-help institutions of support to cope with this AIDS crisis. Lesbians, too, have been involved in developing major programmes of community care. But as symbol, AIDS has been used as part of a conservative backlash to renew the stigmatizing attacks on homosexuality which were so prevalent in the earlier part of the twentieth century. At times, it has looked as if homosexuality was about to become 'remedicalized' as disease. But, ironically, in resisting these attacks the lesbian and gay communities appear to have become stronger, more visible and more political (Kayal 1993).

Since the late 1960s there has been a major development in research, writing and publication around homosexuality—the rise of 'lesbian and gay studies' (Abelove *et al.* 1993; Plummer 1992). In the 1970s, psychologists debunked the 'sick homosexual' and refocused on homophobia—the fear of homosexuality. Sociologists initiated a debate on the homosexual role, the ways in which 'homosexualities' were always 'socially constructed'; and the processes through which people came to identify themselves as gay. Historians and anthropologists researched homosexualities in different settings across the world (Duberman *et al.* 1989). Feminist scholars shaped many important debates on a wide range of matters like sexuality, female relationships, literary texts, and race (Douglas 1990). On all these areas, debates, conflicts and international conferences have proliferated (Altman *et al.* 1989; Weeks 1985).

By the late 1980s a younger generation was bringing a new and challenging strategy: 'queer' theory, 'queer' politics and 'queer' lifestyles. These deconstruct heterosexuality as an organizing assumption of everyday life and replace it with a much wider sense of transgressive differences around sexualities and genders (Sedgwick 1990). It remains to be seen whether this will become a widespread new construction of same-sex desires.

house

The relationship between house form, environment and culture is a theme that has been explored by architects, archaeologists and anthropologists (Guidoni 1979; Rapoport 1969; Wilson 1988). An anthropological focus on the house derives from the way houses have importance in particular cultures, as material constructions, as social groups, and as the subject of symbolic elaboration (Waterson 1991). For example, in many societies, important principles of social classification, such as age and gender, are embodied in the internal arrangement of space within houses. Houses thus become the vehicles of acquiring and perpetuating social distinctions (e.g Bourdieu 1990).

Houses also endure over time and provide fixed points of reference for people. Anthropologists confronted with societies which do not conform to the models of classic kinship theory have turned to the house as a way of comprehending sociality. These societies do not necessarily have lineages, or else these do not function as described in classic ethnographies. Seeing these societies as made up of enduring houses is one attempt—to fit their analysis more closely to indigenous categories.

Lévi-Strauss's (1983a; 1983b; 1987) concept of *'sociétés à maison',* house-based societies, is one such attempt which brings together the material, social and symbolic aspects of the house. Lévi-Strauss's argument relates principally to the Kwakiutl *numayma,* the medieval noble house in Europe, the houses of eleventh-century Japan and

of certain Indonesian societies. The house 'reunites' or 'transcends' (1983a) a series of opposing principles, such as filiation/residence, patri-/ matrilineal descent, close/distant marriage Characteristically, filiation and marital alliance are equally important as well as mutually substitutable (1983b: 1224). Lévi-Strauss (1987) emphasizes how 'alliance' acts as both a principle of unity and of antagonism in house-based societies where neither descent, property nor residence, taken alone, are criteria for the constitution of groups. The married couple is at once the centre of the family but also a source of tension between families—particularly over residence. The house then becomes 'the objectification' of the unstable relation of alliance to which it gives an illusory solidity. In this respect Lévi-Strauss has applied the notion of 'fetishism' to the house, using as examples certain Indonesian cultures with highly elaborated architecture. In other respects, however, Lévi-Strauss pays rather little attention to the material properties of the houses he examines.

Lévi-Strauss's writings have inspired other studies of the house in these terms. Anthropologists have tried to apply his model to the analysis of various societies in South-East Asia (Macdonald 1987). This in turn has led to a critique of his paradigm which appears to subvert the old categories of kinship analysis only to substitute another, equally rigid, one (Carsten and Hugh-Jones 1995). If a focus on the house is to provide an escape from the constraints of kinship theory, it can only do so through a more flexible approach which pays close attention to what people do with houses and how they conceive them in particular cultures. It will bring together the study of architecture with that of kinship, religion and economy, and be based on an understanding of houses and the people who live in them as involved in a single, dynamic process of living.

household

The defining characteristic of household membership is the occupation of living space which is reserved for the exclusive use of that household. In certain populations, however, many other ties may unite members of the household including the pooling of incomes, the taking of at least one main meal together, responsibility for the socialization of the young and the welfare of all members, while the household may even serve as the locus of production. Households are likely to have been largest and most complex when they fulfilled all of these functions. When more of such activities took place elsewhere, as was increasingly likely from the late nineteenth century, the ties between household members were loosened and it became more feasible to live in smaller residential groups or even alone. In increasing numbers of households since the 1960s, it is no longer the case that members of the household take even one main meal together. In Britain the definition of the household as a unit of co-residence and housekeeping was replaced in 1983 with a more flexible definition referring to co-residence in combination with either the sharing of one meal a day or the sharing of living accommodation (*Social Trends* 1984 and 1985).

In 1991, 27 per cent of all British households contained just one person, 11 per cent of the population lived alone and households on average contained 2.5 persons *(Social Trends* 1994). Such small households are not at all unusual in developed populations. For example, an average household size of at least three persons was recorded for only three west European countries at the beginning of the 1990s: Portugal, Spain and the Irish Republic (Begeot *et al.* 1993). In the past larger households were more common. In pre-industrial England the average was 4.75 persons per household and less than 6 per cent of households consisted of persons living on their own (Laslett and Wall 1972). Households were somewhat larger still in rural parts of Denmark in 1787 and in Norway in 1801 (averages of 5.0 and 5.5 persons per household respectively) and considerably larger (over 7.0 persons per household) in many Austrian populations of the seventeenth and eighteenth centuries, and in northern Sweden in the seventeenth century (Lundh 1995; Wall *et al.* 1983). An average of over 9.0 persons per household was reached by a Russian serf population in the early nineteenth century (Czap 1983).

Differences in the kinship structure of the household sometimes underlay these differences in household size. In much of north-western Europe nuclear family households comprising parents and unmarried children predominated, even before industrialization, while complex households involving the co-residence of two or more related couples were more readily formed in parts of southern and in eastern Europe. Within western Europe the composition of households also varied considerably in terms of the numbers of children and servants present and the frequency with which unmarried persons headed households (Wall 1991).

In the case of England two factors in particular account for the fact that in the late twentieth century households are much smaller than those of pre-industrial times: the

decline in marital fertility and the virtual elimination from the household of the resident domestic and farm servants. The incidence of farm service for men declined markedly in most areas of England in the latter part of the eighteenth and early part of the nineteenth centuries, while domestic service (largely performed by women) persisted into the early decades of the twentieth century. The number of children per household (including households where there were no children) fell from 2.1 in 1911, little above the level typical of pre-industrial times, to 1.8 in 1921, 1.3 in 1947 and 0.9 in 1981. Since the end of the Second World War there has also been a marked decline in the frequency with which households are extended to include relatives outside the core couple and parent-child group (Wall 1991; 1995).

Demographic change explains many of the modifications that have occurred in the composition of the household. For example, the fall in fertility of the late nineteenth and early twentieth centuries initiated an immediate decline in the size of the average household and later made it less likely that parents approaching old age would still have unmarried children resident in their households (Wall 1994). Another demographic change to have a profound impact on household and family patterns of elderly people in the post-war period has been the greater improvement in female than in male life expectancy. This has prolonged the period that women spend as widows and therefore at risk of living on their own, while ensuring that many more elderly men than in the past have a spouse to provide primary care in their old age. In England in the eighteenth century, the structure of the household responded to demographic change (Wall *et al.* 1983). An earlier age at first marriage and higher proportions marrying than in the late seventeenth century, together with a fall in adult mortality, increased the proportions of households headed by married couples and led to an expansion in the size of the child population and in the average size of the household. Population growth, by making labour relatively more abundant and therefore cheaper, may also have encouraged farmers in arable areas to switch in the eighteenth century from the use of resident male labour (servants) to labourers who had households of their own and could be employed on a more casual basis.

However, improvements in living standards over the course of the twentieth century, and particularly since the 1950s, have enabled many more people to live alone, who in earlier times would have either lived with relatives or lodged with a non-relative. Variations in the standard of living also exert important but indirect influences on household patterns through alternatively lowering or raising the age at first marriage or cohabitation, thereby increasing or decreasing the pace of household formation. Nevertheless, in England neither urbanization nor industrialization appear to have promoted a major modification in the structure of the household. Even in the middle of the nineteenth century, there were no major differences between the structure of urban and rural households, apart from the greater number of lodgers attached to urban households. The modest increase between pre-industrial times and the middle of the nineteenth century in the number of relatives in the household other than members of the immediate family of the household head was at one time thought to be associated with industrialization (Anderson 1971). However, this increase is now known to have occurred in both rural and urban areas in response to demographic, as well as economic, change (Wall *et al.* 1983).

The impact of cultural influences on the household is less easy to measure. No written rules or customs recommended the formation of specific types of households, identified an appropriate age for children to leave the parental home, or ordered that elderly people should be cared for in the households of their children. Yet the relative uniformity of household and family patterns in the English past, despite contrasting economic and demographic circumstances, implies that residence patterns were influenced by norms, even if these were never written down, and no penalties applied if the norms were not followed.

human capital

Human capital is the stock of acquired talents, skills and knowledge which may enhance a worker's earning power in the labour market. A distinction is commonly made between *general* human capital—which is considered as affecting potential earnings in a broad

range of jobs and occupations—and *specific* human capital, which augments people's earning power within the particular firm in which they are employed but is of negligible value elsewhere. An example of the former would be formal education in general skills such as mathematics; an example of the latter would be the acquired knowledge about the workings of, and personal contacts within, a particular firm. In many cases human capital is of an intermediate form, whether it be acquired 'off the job', in the form of schooling or vocational training, or 'on the job' in terms of work experience.

In several respects the economic analysis of human capital raises problems similar to that of capital as conventionally understood in terms of firms' plant and equipment. It is likely to be heterogeneous in form; it is accumulated over a substantial period of time using labour and capital already in existence; further investment usually requires immediate sacrifices (in terms of forgone earnings and tuition fees); its quality will be affected by technical progress; the prospective returns to an individual are likely to be fairly uncertain, and the capital stock will be subject to physical deterioration and obsolescence. Nevertheless there are considerable differences. Whereas one can realize the returns on physical or financial capital either by receiving the flow of profits accruing to the owner of the asset or by sale of the asset itself, the returns on human capital can usually be received only by the person in whom the investments have been made (although there are exceptions, such as indentured workers), and usually require further effort in the form of labour in order to be realized in cash terms. The stock of human capital cannot be transferred as can the titles to other forms of wealth, although the investments that parents make in their children's schooling and in informal education at home are sometimes taken as analogous to bequests of financial capital.

While the idea of investment in oneself commands wide acceptance in terms of its general principles, many economists are unwilling to accept stronger versions of the theory of earnings determination and the theory of income distribution that have been based on the pioneering work of Becker (1964) and Mincer (1958). This analysis generally assumes that everywhere labour markets are sufficiently competitive, the services of different types of human capital sufficiently substitutable and educational opportunities sufficiently open, such that earnings differentials can be unambiguously related to differential acquisition of human capital. On the basis of such assumptions estimates have been made of the returns (in terms of increased potential earnings) to human investment (measured in terms of forgone earnings and other costs) by using the observed earnings of workers in cross-sectional samples and in panel studies over time. The rates of return to such investment has usually been found to be in the range of 10–15 per cent. However, it should be emphasized that such estimates often neglect the impact of other economic and social factors which may affect the dispersion of earnings.
